John C. Bulkeley
Portland Rd.,
Wallerawang.
1926.

We are proposing to publish, as a supplement to the biographical articles and personal references in the *Australian Encyclopaedia*, a volume containing a List of the most authentic portraits of the persons concerned. Where such a portrait consists of an original painting or drawing, we propose to give the name of the artist and also particulars of the size and the medium employed (oils, water-colours, pastel, pencil, or crayon), together with the name and address of the present owner or the name of the gallery or other institution in which it can be seen.

We should be glad to be supplied with any relevant information by the possessors or custodians of such portraits. No report is required of portraits in published books or magazines, but we desire to record engraving and lithographs published separately and also original photographs where other portraiture is not known to exist.

The proposed volume will be illustrated with small reproductions of any such accessible portraits as a liberal selection will admit. Apart from its natural human interest the book should be a valuable work of reference for those interested in the history, literature, and art of Australia.

Macadamia, a genus of the family Proteaceae, consisting of trees or tall shrubs with verticillate leaves, endemic in eastern Australia. The corolla-tube opens on the underside of the lobes of the petals before they separate; anthers shortly stalked, and produced into a gland or very short appendage; fruit a globular nut, with an exceptionally hard coat. *M. ternifolia* (Queensland Nut—but it is found also in northern New South Wales) is a bushy tree more than 30 feet high, with a stem diameter of 8 inches. The timber is firm and fine-grained, and takes a good polish. The tree (which reaches maturity in about seven years) is ornamental, and during six months of the year bears a crop of edible (but very hard-shelled) nuts of excellent flavour. They are sometimes sold as 'popple' or 'poplar' nuts—a corruption of Bopple Mountain near Gympie in Queensland, where they are plentiful. As they form a nutritious article of food for the aborigines, timber-getters are not allowed to fell the trees. In 1923 a thin-shelled variety was discovered on the Tweed River in northern New South Wales; it improves by cultivation, and is under investigation by the Queensland department of agriculture.

Macarthur, Sir Edward (1789-1872), born at Bath in England in 1789, was in 1790 brought by his father John Macarthur (q.v.) to Sydney and privately educated at Parramatta. He returned to England, and on 20 October 1808 joined the army as ensign in the 60th regiment (lieutenant, 1809; captain, 1819; major, 1826; lieutenant-colonel, 1841; colonel, 1854; major-general, 1858; lieutenant-general, 1866). He served in Spain under Sir John Moore through the campaign of Corunna, in Sicily, and again in Spain and in France under Wellington from Vitoria to Toulouse. His subsequent military career was undistinguished, but he established a reputation for administrative ability; in 1837 he was assistant adjutant-general in Ireland, and in 1851 became deputy adjutant-general in Australia. In 1855 he succeeded Sir Robert Nickle (q.v.) as commander of the British troops in Victoria, in 1856 administered the government of Victoria during an interregnum; he returned to England in 1860, and died in London on 4 January 1872. (C.B., 1857; K.C.B., 1862.)

Macarthur, George Fairfowl (1825-1890), third son of Hannibal Hawkins Macarthur, was born at Subiaco near Parramatta on 19 February 1825, educated at The King's School, Parramatta (he was one of its first pupils), and was afterwards coached by Dr. Woolls (q.v.) to fit himself for Oxford. This becoming impossible owing to his father's losses in the financial crisis of 1843-4, he studied for Anglican orders and was ordained deacon in 1848 and priest in 1849. In 1852 he was appointed to St. Mark's church on Darling Point, Sydney, and while in charge there opened St. Mark's collegiate school; this prospered so greatly that in 1858 he resigned the parish and moved his school to Macquarie Fields, about 27 miles south-west of Sydney. For the next ten years he devoted himself to the school, modelling it on the great public schools of England, and establishing the first cadet corps in Australia. In 1868 he was invited to become head of The King's School, which had been closed since 1864. Though the buildings were much dilapidated and half his pupils were not allowed to follow him from Macquarie Fields, he accepted the post for sheer love of his old school, and during 17 years rebuilt it with such skill and success that he was known as the school's 'second founder.' In June 1886 he resigned, and lived in retirement until his death on 16 June 1890.

Macarthur, Hannibal Hawkins (1788-1861), born at Plymouth on 16 January 1788, in 1805 migrated to New South Wales at the invitation of his uncle John, but after gaining some experience in wool-growing took a cargo of sandalwood to China for his uncle and returned to England in 1808. In November

1812 John Macarthur, finding himself detained in England because of his share in the mutiny against Bligh, persuaded Hannibal to go back to Sydney to manage the commercial side of his various enterprises; but the young man preferred wool-growing, purchased Captain Waterhouse's farm near Parramatta, and there superintended the shipping of John Macarthur's wool. When his uncle returned to Australia in 1817, Hannibal devoted himself to his own estate and in 1820 took up land at Arthursleigh near Goulburn, where he amassed a 20,000-acre estate. Curiously enough though his relations with Macquarie were consistently amicable he fell foul of that mildest of governors, Brisbane, who not only dismissed him from the magistracy but singled him and John Blaxland out as persons who could not be recommissioned when a new commission was issued. In 1830 he was appointed to the legislative council on the death of J. T. Campbell, and held the seat till the abolition of the council in 1843; he would then have been one of the nominated members of the new council had not Parramatta elected him as its representative. His political career was undistinguished. In 1848 he retired, became commissioner of crown lands at Braidwood and afterwards police magistrate at Ipswich in the Moreton Bay district, and in 1853 returned to England, where he died at Norwood near London on 26 October 1861.

Macarthur, JAMES (1798-1867), born at Parramatta in 1798 and in his early years taught by Huon de Kerilleau (see MITCHELL, JAMES), was taken to England with his younger brother William by their father, John Macarthur, in 1809, educated at private schools there, taken on a tour through France and Switzerland in 1815, and brought back to New South Wales in 1817. For some years thereafter he assisted his father in the management of Camden Park, taking also a minor part in the public life of the colony; he revisited England with petitions from the colonists regarding freer institutions, immigration, and the convict system, and while in London took the opportunity to publish in 1837 *New South Wales, Its Present State and Future Prospects.* Returning to Sydney in 1839, he was in October nominated to the legislative council. In 1843 he contested the election for the Cumberland seat, but was defeated, and refused to enter the council as a nominee; in 1848 he was elected by the Camden constituency, and moved the resolutions which sent Wentworth and Deas Thomson to England to ensure the passage through parliament of the act granting New South Wales responsible government. In 1856 Camden returned him to the new legislature, but ill-health forced him to retire in 1859; he refused Governor Denison's offer of a knighthood, visited England in 1860, was a commissioner for the colony at the London exhibition of 1862, returned to Sydney in 1864, and in June 1866 was nominated to the legislative council, of which he was a member when he died on 21 April 1867. He and his brother William were among the pioneers of the wine industry in Australia.

Macarthur, JOHN (1767-1834), born near Plymouth in Devonshire in 1767 and educated at a private school, was the second son of Alexander Macarthur who had been concerned in the Jacobite rising of 1745, fled to the West Indies thereafter, and eventually settled at Plymouth as an army agent. In 1782 John entered the army as an ensign, and at the close of the war in 1783 was placed on half-pay and retired to a farmhouse near Holsworthy, on the borders of Cornwall and Devon; here he read a good deal (principally English and Roman history and the general principles of law), and contemplated resigning his commission with a view to being called to the bar. In 1788, however, he was appointed to the 68th (Durham) regiment, and on 5 June 1789 exchanged into the New South Wales Corps (q.v.), reaching Port Jackson on 18 June 1790. On arrival he was sent as commandant to Parramatta. On 12 February 1793 he was granted 100 acres at Rose Hill, and on 1 April 1794 received a second 100-acre grant, a prize offered to the first man who should clear and cultivate 50 acres; here he erected a 'very excellent brick building,' and called the place 'Elizabeth Farm' in honour of his wife. In the same year he was appointed superintendent of public works by Lieutenant-governor Grose, and became paymaster to the regiment.

Meanwhile he made farming the serious business of his life. On 26 February 1796 he retired from the superintendency, and quarrelled violently with his successor and Governor Hunter; when they complained to the British authorities, Macarthur replied by charging Hunter with laxity—but apart from a voluminous correspondence nothing occurred.

In 1796 he imported merino sheep of poor quality from The Cape Colony and began experimenting with their wool, meanwhile adding to his estates and his influence with his fellow-officers (who were all traders at heart) by steady and profitable attention to his wheat-growing and stock-breeding. When he went to England in 1800 to investigate the merino breed more carefully, Governor King plaintively suggested to the colonial office that 'if Captain Macarthur returns here in any official character, it should be that of Governor, as one-half the colony already belongs to him, and it will not be long before he gets the other half.'

Returning to New South Wales in 1801, Macarthur embroiled himself during September in a quarrel with his commanding officer Colonel Paterson, and in the ensuing duel Paterson was badly wounded. King placed Macarthur under arrest, and then hoped to end the matter by sending him as commandant to Norfolk Island; but Macarthur refused to accept release from arrest and demanded a court martial, whereupon King sent him to England to stand his trial there. The results were equally unpleasant for both. Macarthur was promptly ordered back to New South Wales on the ground that all the witnesses were there and no trial could take place without them; the Duke of York, who was then commander-in-chief of the British army, issued a general order in which King was rebuked for trying to shift responsibility off his own shoulders, and Macarthur was told flatly that he had no right to demand a court martial if King chose to release him. This rebuke ended Macarthur's military career; he threw up his commission, and devoted himself to persuading important people in England that the finest wool in the world could be grown in Australia. Procuring merino rams of excellent quality from King George's own flocks, he went back to Australia in 1805 with a permit from Lord Camden, then in charge of the colonies, to choose 5000 acres of land in any situation he liked. The grant would have been for 10,000 had not Macarthur antagonized Sir Joseph Banks

by showing irritation at the great man's rather casual treatment of him; Banks retaliated by advising Lord Camden to halve the grant until Macarthur had fully proved his contentions about the quality of his wool.

Back in New South Wales, the eager wool-grower blocked his own path by insisting on choosing his 5000 acres at the Cowpastures, a reserve sacred to government-owned cattle. King protested, and referred the matter to England, but before an answer could be received he had been replaced in the governorship by Bligh. Meanwhile Macarthur had been allowed to occupy the disputed area provisionally, had transferred to it the major part of the stock from his Parramatta farms, naming it 'Camden Park' after the minister who had favoured him. Bligh, confronted at once with this *fait accompli* and with a renewed order from the colonial office to confirm the grant—and firmly convinced that this aggressive Macarthur was at the bottom of all the trouble with the New South Wales Corps which he had been sent out to settle—rated him soundly for wanting so much land, and took every opportunity to harass him. In 1807 a convict escaped in a schooner that had been chartered by Macarthur, and gave Bligh another grievance. Towards the end of the same year Macarthur imported two stills—for perfectly legitimate uses, he said; Bligh ordered that they should be reshipped, and that for the offence of importing them Macarthur should be tried by a criminal court, which in those days consisted of seven military officers and the judge-advocate, Richard Atkins. Macarthur resisted arrest and, when at last brought before the court, objected to its jurisdiction on the ground that Atkins was his inveterate enemy. Atkins ordered him to prison; the other officers granted him bail; Bligh intervened and had him thrown into prison on an escape warrant; Johnston, then in command of the Corps, signed an order for his liberation, and allowed himself to be persuaded to depose Bligh, assume the government, and appoint Macarthur colonial secretary.

While Johnston remained in command, Macarthur was practically the ruler of the colony, but Paterson when he took charge in January 1809 sent both Johnston and Macarthur to England for trial. After hearing both sides informally—and especially after receiving from Bligh a mass of letters written in a very bad temper, in which he made accusations against everybody he could think of—the British government was not anxious to put anyone on trial. Johnston insisted, and had to be cashiered; Macarthur remained untried, but was forbidden to return to Australia until he admitted wrong-doing and promised to behave himself. This he refused to do, and remained in exile until 1817, when Lord Camden thought him sufficiently punished and allowed him to return unconditionally. The rest of his life was spent mainly at Camden in the supervision and improvement of his live stock and estates. In 1822 the Society of Arts in London awarded him two medals, one for having exported to England 150,000 lb. of fine wool, the other for bringing his wool up to the standard of the best Saxon merino. In 1825 he was nominated to the New South Wales legislative council, of which he remained a member till his death on 10 April 1834.

In a letter to his wife written in 1809 Macarthur described his son John in words that might well be applied to himself:—

> . . . Under this softness I can discover an indescribable fierceness of independence and an obstinacy to pursue what he has once determined on, which neither reason nor dread of future consequence are likely to operate upon him to relax.

Few of his official superiors had a good word for him, and many of them thought him self-seeking, mutinous, and greedy. But among his equals he was often liked and always respected; what really angered the others was his 'indescribable fierceness of independence.' Strong and able—possibly the ablest man except Macquarie among the founders of Australia—he left among his contemporaries the impression of a hard and sometimes vindictive spirit; but his worst faults, whatever they may have been, are atoned for by his genius as a sheepbreeder and his gift of the merino sheep to his country. One among his virtues deserves special notice. In an age, and a community, notorious for its licentiousness, when it was considered proper to include a list of concubines in an official return, Macarthur's life was irreproachable and his affection for his family sincere, lasting, and noble.

See BLIGH, WILLIAM, JOHNSTON, GEORGE, SHEEP, and WOOL.

Macarthur, SIR WILLIAM (1800-1882), born at Parramatta in December 1800, in 1809 went to England with his father John Macarthur and his brother James, was educated at Grove Hall Academy, Bow, and returned with them to New South Wales in 1817. He devoted himself to farming, assisting his father in various projects, and in 1839 brought out six German vine-dressers to improve the Camden vineyards. In 1841 he gained medals in London for exhibits of wine and brandy, and in 1844 published a book *On the Culture of the Vine, Fermentation, and the Management of Wine in the Cellar.* He sat in the New South Wales legislative council from 1849 to 1855, when he was made New South Wales commissioner for the Paris exhibition; reaching England late in March, he found that no place had been reserved for the exhibits, but rectified the blunder, worked hard to display the Australian products, and at the close of the exhibition was decorated with the Legion of Honour by the French emperor. He returned to the colony in 1857 and resumed his work at Camden Park, repeated his Paris success at the London exhibition of 1862, and after his return to the colony in 1864 was nominated to the legislative council; but he cared little for politics—to which his brother and constant companion James was devoted—and his seat lapsed through absence in August 1882. He died unmarried on 29 October 1882. (Kt. Bach., 1856.)

Macartney, HUSSEY BURGH (1799-1894), son of Sir John Macartney, baronet, a member of the last Irish house of commons, was born at Dublin on 10 April 1799 and educated at Trinity College, Dublin (B.A., 1821; D.D., 1847). After taking his degree he entered the Irish Church (deacon, 1822; priest, 1823), and held cures in the dioceses of Meath, Ardagh, Ross and Kildare. In 1847 Bishop Perry of Melbourne invited him to take up work in Australia. He reached Port Phillip on 24 January 1848, and was appointed to the parish of Heidelberg; in November he became archdeacon of Geelong, in January 1852 was made dean of Melbourne and incumbent of St. James's church, and from January 1855 to April 1856 administered the diocese of Melbourne in Bishop Perry's absence. In 1857 he became archdeacon of Melbourne, and in 1860 gave up parish work and devoted himself entirely to the

diocese, which he again administered from January 1863 to September 1864, from February 1874 to January 1877 in the interregnum between the bishoprics of Dr. Perry and Dr. Moorhouse, and from March 1886 to March 1887 in that between Dr. Moorhouse and Dr. Goe. He represented his diocese in two general synods. In 1864-6 he visited England and Ireland. He died at Melbourne on 8 October 1894 (see MISSIONS).

McCallum, FRANK, better known as Captain Melville, was transported to Tasmania in 1838; in 1852 he took to bushranging on the roads leading from the Victorian goldfields to Melbourne, and by the end of the year had a price on his head for daring highway robberies. On 24 December he boasted in Geelong of his exploits, and the police chased and captured him. He was convicted of highway robbery, sentenced to 32 years' penal servitude, and confined on the hulk *President*. A year later he was removed to the *Success* (q.v.), where discipline was less harsh, and was permitted to work in the government stone-quarry at Point Gellibrand. On 22 October 1856 he and other convicts who were being conveyed to work suddenly overpowered the guard, killed the corporal, and pulled away in a boat, but were soon overtaken. McCallum was sentenced to death but reprieved. He was removed from the *Success* to the Melbourne gaol shortly before the murder of John Price (q.v.) on 26 March 1857, which he had possibly helped to plan. On 28 July he savagely attacked the governor of the gaol, and shortly afterwards became subject to paroxysms of fury such as precede dementia. He committed suicide in his cell on 11 August 1857. See BUSHRANGING.

MacCallum, SIR MUNGO WILLIAM, born at Glasgow in Scotland in 1854, and educated at the Glasgow high school and the university of Glasgow (B.A., 1875; M.A., 1877; LL.D., 1907), won the Luke fellowship at his university and afterwards studied at Berlin and Leipzig. In 1879 he was appointed professor of English literature and history in the university of Wales, and in 1887 became Challis professor of modern literature in the university of Sydney. This chair he held uninterruptedly until 1920; resigning then, he was nominated professor emeritus and—the chair having been divided into four when he left it—honorary professor of English literature. In 1898 1914 and 1916-19 he was dean of the faculty of arts and an ex-officio member of the senate: since 1919 he has been an elected member of that body. In 1924 he was made vice-chancellor under a new act of parliament which gave that name for the first time to the chief administrative officer of the university (previous vice-chancellors had been merely deputy-chairmen of the senate, appointed annually.) Professor MacCallum was in 1906-12 chairman of trustees of the public library of New South Wales, and is a member of the Commonwealth literary pensions board; in 1925 the university of Oxford made him an honorary D.Litt. Among his many published works the most notable are *Studies in Low German and High German Literature* (1883), *Tennyson and the Arthurian Legend* (1894), and *Shakespeare's Roman Plays and Their Background* (1910). (K.C.M.G., 1926.)

McCaughey, SIR SAMUEL (1835-1919), born at Tullynuey near Ballymena in county Antrim, Ireland, on 1 July 1835, migrated to Australia at the age of 20 and reached Melbourne in April 1856. After three months' experience as a 'jackeroo' on Kewell station in the Wimmera (which belonged to his uncle Charles Wilson), he was made manager of the station. In 1860 he with two partners bought Coonong station in the Narrandera district of New South Wales, and there he built up a remarkable stud flock; its foundation was a draft of Widgiewa ewes and one of rams from Mona Vale in Tasmania, owned by R. Q. Kermode (see SHEEP). In 1883 he bought ten Californian rams and some American ewes in Sydney, and was so satisfied with his purchase that he shortly afterwards visited the United States and brought back 524 stud sheep selected from the best strains in Vermont—spending in all about £50,000. He was among the first breeders to realize that sheep were to be valued for their mutton as well as for their wool; and side by side with the Coonong stud he established flocks of large-framed sheep from Wanganella, Boonooke, and South Australia. In 1880 he bought Toorale and Dunlop, two large stations on the Darling River south-west of Bourke, and in 1881 invested largely in Queensland stations. At one time he shore a million sheep every year.

He was an early and persistent advocate of irrigation for pastoral as well as for agricultural uses. In 1899 he bought North Yanco on the northern banks of the Murrumbidgee, and from a dam and pumping-station a few miles above the estate constructed many miles of channel to irrigate 40,000 acres, on part of which he grew lucerne and other fodder-crops, running stock on the remainder. The object lesson was so lucid that the New South Wales government arranged to establish on North Yanco an experimental farm, and in the end bought the station from McCaughey and constructed the gigantic Burrinjuck dam (see IRRIGATION) to impound water for the supply of a great irrigation settlement. By this time (1911) McCaughey, who had devoted himself almost vehemently to his work both as breeder and as irrigationist, was growing old; in 1911-12 he sold Toorale and Dunlop and his Queensland stations, and retained only Coonong, his original New South Wales home. This property he sold in June 1919 to Roy McCaughey, his nephew. From 1899 to 1919 he was a member of the New South Wales legislative council.

His benefactions were among the most generous ever known in Australia. He gave £5000 to aid the 'bushmen's contingent' in the South African war (q.v.), £10,000 to the 'Dreadnought' fund, and £25,000 to the Red Cross funds, besides insuring 500 recruits against death or total disablement. He also gave liberally to the Salvation Army and the Burnside Homes (see BURNS, SIR JAMES). Dying at Yanco homestead on 25 July 1919, he bequeathed over £300,000 to the university of Sydney, £250,000 to that of Queensland, £250,000 to the Presbyterian Church authorities in New South Wales and Queensland (including £20,000 to the Scots College in Sydney and £26,000 to the Burnside Homes), £10,000 each to four other Sydney schools, £5000 each to three Sydney hospitals, and £5000 to the Salvation Army. Perhaps his most valuable legacy was one devoted to the technical training of the children of deceased or totally disabled soldiers, under the administration of the A.I.F. Canteens Funds Trust. Fifteen thousand such children will benefit by this bequest, which will yield about £600,000. (Kt. Bach., 1905.)

M'Cay, Sir James Whiteside, born at Ballynure, Ireland, on 21 December 1864, one of a brilliant family well known in Australian journalism, was educated at Scotch College and the university of Melbourne (M.A., 1892; LL.M., 1895), and called to the Victorian bar in 1895. He entered the house of representatives as member for Corinella in 1901, and became minister for defence in the Reid government of 1904-5. He was a keen member of the militia (lieutenant, 1886; captain, 1889; major, 1896; lieutenant-colonel, 1905; colonel, 1907; brigadier-general, 1914; major-general, 1915), and at the outbreak of the war in 1914 General Bridges chose him to organize and command the 2nd (Victoria) infantry brigade. After putting it through a training remarkable for its severity and thoroughness at Mena Camp, he commanded it at the landing on Gallipoli, and personally led a portion in its famous advance on 8 May 1915 at the second battle of Krithia. Being wounded that night on the battlefield, he was invalided to Australia where he acted for a time as inspector-general, but after the evacuation of Gallipoli was appointed to command the 5th division then forming in Egypt. He trained this division and commanded it in the battle of Fromelles, for the unfortunate issue of which he was in no way responsible. Being noted for his thoroughness, he was in 1917 appointed to command the A.I.F. training depots in England, a position which he occupied until the end of the war. (C.B., 1915; K.C.M.G., 1918; K.B.E., 1919). See Australian Imperial Force.

C.E.W.B.

McCoy, Sir Frederick (1823-1899), born in Dublin in 1823 and educated there and at Cambridge, was diverted from the practice of medicine (for which he had been trained) by obtaining a commission to arrange collections of specimens for the Geological Society of Ireland and the Royal Irish Academy. He was next employed on certain palaeontological enquiries, and in 1846 was invited to Cambridge by Adam Sedgwick to arrange a collection in the university's Woodwardian Museum. During this engagement he was appointed in 1850 to the chair of mineralogy and geology at Queen's College, Belfast, and carried on his two tasks side by side until 1854, when his Cambridge work was completed, and he was able to embody its results in *British Palaeozoic Rocks and Fossils.* In that year he was made professor of natural science in the newly established university of Melbourne, and found himself expected to control the study of geology, zoology, palaeontology, botany, mineralogy, chemistry, and even comparative anatomy; of these subjects he chose the first four for his own, and handed on the others as soon as possible to other teachers. During his tenure of the chair he published a *Prodromus of the Palaeontology of Victoria* (1874-82) and a *Prodromus of the Zoology of Victoria* (1885-90), but his most important contribution to the progress of the colony was the establishment and building up of the National Museum. This, when he took charge of it, was merely a collection of stuffed animals housed in the crown lands office; McCoy removed it (in spite of protests from the Philosophical Society) to the university, and managed it till his death, defying or evading all attempts to put it under the control of trustees. His other scientific activities were manifold, but of less importance. Cambridge in 1886 made him a D.Sc., the Geological Society of London awarded him the Murchison medal (1879), the Royal Society made him a fellow (1880), and he received other honours from Italy and Austria. He died at Brighton Beach near Melbourne on 13 May 1899. (C.M.G., 1886; K.C.M.G., 1891.)

McCrae, George Gordon, born at Leith in Scotland on 29 May 1833, is the son of Andrew Murison McCrae, writer to the signet, who in 1839 at the suggestion of his friend Sir T. L. Mitchell migrated to Sydney, but settled almost at once in the new township of Melbourne. The family reached Melbourne on 1 March 1841, and Andrew McCrae took up land for a cattle-run near Arthur's Seat. After a short experience of commercial and banking work, G. G. McCrae on 1 January 1854 entered the office of the Victorian auditor-general, and after promotions through several government departments reached the position of deputy registrar-general, from which he retired, having reached the statutory age-limit, in 1893. He has since lived in retirement at Hawthorn, a suburb of Melbourne. McCrae's chief service to his country, however, has been rendered outside his official life. Joining during the sixties the coterie of literary men—R. H. Horne, Marcus Clarke—who founded the Yorick Club, made the reputation of the *Colonial Monthly,* and attracted into their circle both Adam Lindsay Gordon and Henry Kendall, he began to devote his leisure to authorship, and in 1867 produced two ballads of aboriginal life—*The Story of Balladeadro* and *Mamba the Bright-eyed.* In 1873 he published *The Man in the Iron Mask,* which some critics consider his masterpiece, others preferring the later *Rosebud from the Garden of the Taj* (1883), which was published only in the *Melbourne Review.* Though his verses are widely scattered through many Australian periodicals, the only other volume of verse yet published is *The Fleet and Convoy* (1915). A novel, *John Rous,* appeared in 1918: but other novels, besides dramas, poems, and the third of his ballads of the aborigines (*Karakorok*), are still unpublished.—His second son, Hugh Raymond McCrae, born at Hawthorn in 1876, is notable among the younger school of Australian poets; his published volumes are *Satyrs and Sunlight* (1909), *Colombine* (1920), and *Idyllia* (1922), and (in prose) *The Du Poissey Anecdotes* (1922).

McCron, Francis (1810-1853), better known by his stage-name Francis Nesbitt, was born in Ireland in 1810 and against his family's wishes adopted the stage as a profession, becoming a member of a travelling company in which he met G. V. Brooke and Barry Sullivan; during a visit to Glasgow he also met Gordon Griffiths, who was subsequently engaged to perform at the Victoria theatre in Pitt-street, Sydney. In 1840 he returned to Ireland, married, and migrated to Sydney, which he reached on 7 January 1841 in the *Marchioness of Bute.* His letters of introduction (one to Governor Gipps was not delivered) procured him the post of tide-waiter in the customs, but he quarrelled with a superior officer, and after one night's experience of police duty applied for work at the Victoria theatre. He was engaged to appear as Pizarre, became popular, and revived the falling fortunes of the theatre; when the owner opened the City theatre in Market-street on 20 May 1843, Nesbitt spoke the opening address, which had been written by William a'Beckett (q.v.). During the next few years he played in Launceston, Hobart, Melbourne, and Adelaide, but in 1846-7 reappeared at the Vic-

toria theatre, and towards the end of 1847 retired to Maitland, where he supervised an amateur company. In 1849 the Californian gold-rush attracted him to San Francisco; there he played at the Kearney-street theatre under his own name, McCron, but quarrelled with the local actors, and was forced to leave the stage and seek the diggings. It is said that on his way back from them, having had no luck, he was 'stuck up' by a gang one of whose members was an Australian; appealing to this man, and satisfying him by a recitation of Tell's address to his native mountains (from a translation of Schiller's 'William Tell') that he really was Nesbitt, he was released, nursed back by the gang to health and good spirits, and sent back to the coast with means to return to Sydney. He did not, however, renew his former successes; he made appearances at Sydney, Melbourne, and Geelong, and collapsed during a performance at the Geelong theatre, dying next day—29 March 1853. G. V. Brooke afterwards erected a headstone over his grave in the Geelong cemetery. See DRAMA.

McCubbin, FREDERICK (1855-1917), born at Melbourne on 25 February 1855, studied art at the artisans' school of design and the national art school, where he with Tom Roberts and C. D. Richardson formed the first life-class. In 1884 he was appointed drawing-master at the national art school, and in 1891 temporarily directed it. In 1885 he and Tom Roberts established the first of the famous artists' camps at Box Hill, near Melbourne, and he was thrice president of the Victorian Artists' Society (1903-4, 1908-9, 1911-12). In 1912 he helped to initiate the Australian Art Association. As far back as 1897 he exhibited at the Old Salon in Paris, and later at the Grafton galleries in London, but visited Europe for the first time in 1907. He died at Melbourne on 22 December 1917.

McCubbin was a student in the days when the copying of studio pictures was the normal method of art instruction and even inspiration, and he never quite lost the habit of producing arranged and 'composed' work. But his natural instincts were for open-air painting and the straightforward delineation of sincere human interest. In a series of notable pictures which included 'Down on his Luck,' 'A Bush Burial' (at Geelong), 'On the Wallaby' (in the Sydney gallery), and 'Pioneers' (in the Melbourne gallery), he depicted the pathetic side of the early settlers' life. In later years he was content to paint pure landscape. As a portrait-painter he was unequal, his best work in this kind being portraits of J. A. Panton, Louis Abrahams, and Alfred Deakin. W.M.

McCulloch, ALLAN RIVINGSTONE (1885-1925), born at Cabarita near Sydney on 20 June 1885, obtained employment at the Australian Museum in July 1898, and worked there for three years as a volunteer before becoming a permanent member of the staff. Early in 1906 he was placed in charge of the vertebrate section of zoology, and began to concentrate his attention on the study of fishes. The carelessness (or incapacity) of several early workers in Australian ichthyology had left that science in an unsatisfactory condition, and McCulloch determined to place it on a sound basis; by dint of industry and perseverance, combined with natural aptitude and an intense love of his subject, he attained his object, and in 1922 published a *Check List of the Fishes of New South Wales* which is both brilliant in conception and fundamentally sound. His many papers on ichthyology contributed to scientific journals are noted for their accuracy and draughtsmanship. He was already ranked among leading ichthyologists when, exhausted by incessant work, he died at Honolulu on 1 September 1925, while attending the second Pan-Pacific Food Conservation Conference. T.C.R.

McCulloch, SIR JAMES (1819-1893), born at Glasgow in 1819 and trained for mercantile pursuits, while still young entered the employ of Messrs. J. and A. Dennistoun, and in 1853 was sent as a junior partner to Melbourne to open a branch of the firm there. In 1854 he was nominated to the old council, and when a new legislature was elected under the system of responsible government in 1856 he was returned to the assembly by the Wimmera. In 1857 he was commissioned by Barkly to form a ministry, but finding himself unable to procure a coalition took office as commissioner of customs under W. C. Haines (1857-8). He was afterwards treasurer under W. Nicholson (1859-60). When in 1863 the third O'Shanassy ministry resigned office, Barkly again appealed to McCulloch, who formed what was by far the strongest cabinet the colony had seen or was to see for many years; it included Higinbotham, Michie, Verdon, Heales, and Francis, held office continuously for 5 years (27 June 1863 to 6 May 1868), after a short interval regained it for another 14 months (11 July 1868 to 20 September 1869), and after a rather longer interval returned to office for a similar period (9 April 1870 to 19 June 1871). McCulloch's term of office was notable for several violent political episodes, particularly in connection with the establishment of a protective tariff and with the 'Darling grant.' The struggle over the tariff was much embittered by McCulloch's methods of passing it. Backed by the assembly, but confident that the council would reject any separate bill for a protective tariff, he 'tacked' his new scale of duties on to the ordinary appropriation bill for 1865; the council, debarred by the constitution from amending a money bill by the omission of individual clauses, laid the bill aside; McCulloch went on collecting the new duties despite a judgment of the supreme court ordering him to refund them, and with the aid of Sir C. Darling devised a legal but high-handed method of paying official salaries and other public obligations without the sanction of an appropriation act. At the end of 1865 a general election, amid intense excitement, gave him an increased majority, and during 1866 a compromise was effected, McCulloch dropping the 'tack' and the council passing the tariff in a separate bill. By this time, however, the British government had interfered. Darling was their officer, and in their opinion should have refused to allow the collection of duties as soon as the supreme court had ordered restitution, while his acquiescence in the trick by which salaries, etc., had been paid was even more blameworthy. This censure became known; McCulloch's friends organized demonstrations of sympathy with the governor; Darling, always weak and now overexcited, betrayed his resentment of the censure and proceeded to attack personally several local politicians who had opposed him; his recall was thus made inevitable. The assembly, guided by McCulloch, promptly voted him an address in which he was praised as a peacemaker and told that he had steadfastly adhered to the principles

of constitutional government, and emphasized its opinions by voting a grant of £20,000 to Lady Darling to compensate her husband for the pecuniary loss caused by his recall. The sequel is told under DARLING, SIR CHARLES; it may be said here that McCulloch's loss of office in May-July 1868 was due to a quarrel with the British authorities over this grant, and that by July Darling had made his peace with those authorities and the grant was no longer required.

McCulloch's ministry of 1870-1, though it carried the abolition of state aid to religion, was far less advanced in views than his earlier ministry, and he himself was slowly growing conservative. He had never been a convinced protectionist, and could not accept the demands for increased protection that Graham Berry and his followers were incessantly pressing on him. Further, he had lost Higinbotham, whose support had always assisted his popularity. In June 1871 Duffy and Berry ousted him, and in August 1872 he retired to the agent-generalship. In 1875, however, he returned to Victoria and to Parliament as a supporter of Berry, but when Berry took office with a policy of land-taxation, he turned him out and formed another ministry (20 October 1875 to 21 May 1877), chiefly notable for its introduction of the closure as a piece of parliamentary machinery. By now, however, he was identified with the squatter party, and the elections of 1877 finally ejected him from politics. In 1885 he left Australia, and died at Ewell in Surrey on 31 January 1893. (Kt. Bach., 1869; K.C.M.G., 1874.)

MacDonnell, SIR RICHARD GRAVES (1814-1881), son of the Richard MacDonnell who was late in life provost of Trinity College, Dublin, was born in Dublin on 3 September 1814, educated at Trinity College (B.A., 1835; M.A., 1836; LL.B., 1845; LL.D., 1862), called to the Irish bar in 1838 and to the English in 1841, and in 1843 made chief justice of the Gambia colony, of which in 1847 he became governor. In 1852 he was transferred to St. Lucia, and the next year to St. Vincent. During these periods of office he had won the reputation of being a courageous explorer and a good organizer, but one inclined (as is necessary in mainly negro colonies) to exercise an autocracy which English settlers would resent. The choice of him by the colonial office to succeed Sir Henry Young (q.v.) in South Australia at the very moment when important constitutional changes were being made—and those in the direction of fuller self-government—was therefore unexpected. Reaching Adelaide on 8 June 1855, he dissolved the legislative council and promulgated his own scheme for a new single-chamber constitution. This scheme had to be withdrawn almost immediately in favour of a copy of the Tasmanian constitution, that again being much amended and liberalized before it was enacted and brought into force. Throughout the long struggle MacDonnell's influence was persistently conservative, and his reserved and often dictatorial attitude towards his ministers caused unnecessary friction, for which his great abilities did not compensate; one result was to make the South Australian constitution more democratic than it would have been, and far more so than that of any other colony at the time. When, however, it was promulgated, and the governor's powers were no longer those suitable in a crown colony, MacDonnell adjusted himself to the new conditions quickly and thoroughly, and became both popular and useful. Among the important events that occurred during his term of office were the passing of the Torrens act (q.v.), the construction of railways from Adelaide to the Burra, most of the explorations of J. McDouall Stuart, and the annexation of the 'no man's land' between longitude 132° E. and the border of Western Australia. On 4 March 1862 MacDonnell retired, his term being at an end; after a holiday, he was appointed governor of Nova Scotia (1864-5) and subsequently of Hong Kong (1865-72). He then retired from the colonial service on a pension and died at Hyères in France on 5 February 1881. (C.B., 1852; Kt. Bach., 1855; K.C.M.G., 1872.)

McEncroe, JOHN (1795-1868), born near Cashel in Ireland on 26 December 1795, educated at Maynooth, and ordained priest in 1819, taught for a short time at the Meath diocesan seminary and was then transferred to the diocese of Charleston in the United States, where for seven years he acted as vicar general to Bishop England. His health then gave way, and he returned to Ireland; not long afterwards he was offered an American bishopric, but preferred to join the Australian mission, to which J. H. Plunkett (q.v.) procured his official appointment as an additional chaplain. In 1832, before he left Ireland, Plunkett described him as 'a very respectable Clergyman, prudent in the discharge of his duties in this Country, and never mixing himself with any of its political parties.' Reaching Sydney on 17 June 1832 he at once won the affection of Father Therry, and worked harmoniously with him, but (having had wider experience of diocesan work) saw that the provisional attachment of the Australian mission to the diocese of the Mauritius was unworkable. From the first, therefore, he sent to Rome strong recommendations that a bishopric should be established in Australia, and the credit of obtaining one is largely his. From 1839 to 1841 he was stationed at Norfolk Island, where he erected the first Catholic chapel. Apart from his regular duties —which were carried on until his death with a broad-mindedness and level-headedness that greatly enhanced their value—he is specially noted as the founder of the *Freeman's Journal* in 1850. When in 1854 Dr. Davis, the coadjutor-archbishop of Sydney, died during the absence of Archbishop Polding in Rome, it was Father McEncroe whom the local clergy unanimously chose to administer the diocese. Though vigorously opposed to Archbishop Polding's choice of priests for the Sydney mission, he was, after Ullathorne's departure, the archbishop's confidential adviser in every forward movement, and the reorganization of the Catholic schools after Parkes's first education act was largely his work. Dr. Polding made him dean of the cathedral and, later, archdeacon of the diocese, and in the latter capacity he visited Rome and Ireland in 1858-9 and selected Dr. Forrest of Maynooth to be first rector of St. John's College within the university of Sydney.

His interest at this time, an interest which he did not attempt to conceal, was to bring out Irish priests to minister to the Catholics of Sydney, who were chiefly of Irish descent. Failing to secure a change in the archbishop's policy, he advocated the formation of new suffragan sees, from which the Benedictine influence would be kept out. For this policy, in the circumstances of the colony, there is a good deal to be said, and McEncroe's motives were completely apostolic. His last mission was that of St. Patrick's on Church Hill, Sydney, where he

worked until his death on 22 August 1868. A short, inadequate biography was published in 1868 by J. G. O'Connor of Sydney. E.M.O'B.

MacGillivray, JOHN (1822-1867), son of the eminent Scottish naturalist William MacGillivray, born at Aberdeen on 18 December 1822, studied medicine at Edinburgh, but before completing his course was in 1842 appointed assistant-naturalist to Professor Jukes in H.M.S. *Fly*, then under orders to survey Torres Straits, southern New Guinea, and the eastern coast of Australia. Returning to England in 1846, he obtained a similar appointment in H.M.S. *Rattlesnake* under Owen Stanley, with T. H. Huxley as a fellow-worker. Of this voyage (which ended in 1850) he wrote a *Narrative of the Voyage of H.M.S. Rattlesnake*, (London, 1852). Late in the same year he joined H.M.S. *Herald* as naturalist, with a view to surveying western South America and the neighbouring islands; but in 1855 he left the ship at Sydney, joined a party of sandalwood traders, spent five years in the South Sea islands, and made numerous and valuable collections, especially of island plant. He died at Sydney on 6 June 1867, and his herbarium was sent to Sir W. J. Hooker to be preserved at Kew Gardens near London.

McGowen, JAMES SINCLAIR TAYLOR (1855-1922), was born at sea on 16 August 1855, and three weeks later was taken ashore at Melbourne. In 1870 he was apprenticed to boiler-making, and in 1875 entered the service of the New South Wales railways. Becoming prominent in his trade union, he was in July 1891 returned by Redfern (the Sydney suburb in which the railway workshops are situated) to the legislative assembly, and represented the constituency without a break until 1917; losing his seat in February of that year, he was in May appointed to the legislative council, and was a member of that body till his death. In 1894 he was chosen leader of the Labour party in the New South Wales parliament, and after many strenuous years became on 21 October 1910 the first Labour premier and treasurer of his State. He was early in 1911 summoned to London to represent the State at the coronation of King George V, and during his absence the party leadership fell into the hands of a more active subordinate, so that on McGowen's return he was induced to surrender all real power and content himself with less important offices. On 30 June 1913 he was replaced in the premiership by William Arthur Holman, under whom he served for seven months as minister for labour; he then left office, and remained a private member until in 1917 he was defeated at the polls because he favoured conscription during the war—a policy to which the Labour party in 1916 and onwards was bitterly opposed. For a time he was chairman of the housing board in connection with repatriation (q.v.), and in 1921-2 was a state censor of cinematograph films. In youth he was an ardent cricketer and active in establishing the system of electoral cricket; he was also a pioneer of the eight-hour movement. He died at Petersham, a suburb of Sydney, on 7 April 1922.

McGregor, GREGOR (1848-1914), born at Kilmun in Scotland on 18 October 1848, and educated privately, in 1867 obtained employment in the Clyde shipbuilding yards, but in 1876 migrated to South Australia and took up farming. After 11 months of this work he met with an accident which made him practically blind for the rest of his life; finding it difficult to obtain permanent employment, he was from 1885 to 1891 a builder's labourer in Victoria. In 1891 he returned to South Australia and became an active member of the local Labour party, being elected in May 1894 by the Southern District to the legislative council as a Labour representative. In March 1901 he left state politics to enter the federal senate as one of the six South Australians, and retained this position until his death, leading the Labour section of the senate during the whole period. In each of the three Labour ministries (Watson, 1904; Fisher, 1908-9; Fisher, 1910-13) he was vice-president of the executive council, and in the parliament of 1913-4 led the opposition in the senate. He was one of the most temperate and most widely trusted of Labour leaders, and his death on 13 August 1914, while standing for re-election, was regretted by friends and opponents alike.

MacGregor, SIR WILLIAM (1846-1919), born on 21 October 1846 at Towie in Aberdeenshire, was the eldest son of John MacGregor, a farm-labourer. He received part of his early education at the Strathdon manse, and afterwards taught in a small school at Tillyduke. In 1865-7 he attended the Aberdeen grammar school, in 1867 entered King's College, Aberdeen, and took an arts course, but soon afterwards changed his intentions and studied medicine, first at Glasgow and then at Aberdeen (M.B. and C.M., 1872; Watson gold medal; L.R.C.P. Edin., 1872; M.D., 1874; hon. D.Sc. Camb., hon. D.Sc. Q'ld.). He also studied at Berlin, Florence, and Paris. In 1872 he was for a time resident medical officer at the Glasgow royal infirmary and at the Aberdeen lunatic asylum; but chest weakness compelled him to migrate to the Seychelles, where in 1873 he became assistant medical officer; in 1874 he was appointed surgeon of the Port Louis civil hospital in the Mauritius. From 1875-88 he was chief medical officer in Fiji, at times also acting as receiver-general, commissioner for lands, colonial secretary, and auditor, and on several occasions as high commissioner and consul-general for the western Pacific. In 1876 he suppressed a disturbance in the mountains of Viti Levu, and in 1877 was appointed a member of the native regulation board. In 1879 he reported on the financial condition of Tonga. In 1886, as colonial secretary to the Fiji commission, he sat at the first federal council of Australasia; here he made a great impression on Sir Samuel Griffith, who was instrumental in having him appointed administrator of British New Guinea in 1888 (lieutenant-governor, 1895). In 1899 he was made governor of Lagos, where he opened up large tracts of country with roads and railways, and during his term represented the West African colonies and protectorates at the coronation of King Edward VII. In 1904 he was transferred to Newfoundland, where he endeavoured to stamp out tuberculosis, which was then overrunning the island.

On 2 December 1909 he became governor of Queensland, retiring in July 1914. In April 1911 he was elected first chancellor of the university of Queensland, which came into being largely through his efforts. During the war his great knowledge of Pacific affairs was utilized by the colonial office in considering the future of that part of the world. On 3 July 1919 he died at Aberdeen.

MacGregor was a man of many parts, sincere, discriminating, and courageous. In Papua his best work (by his own judgment) was (*a*) the

establishment of a native police-force and a system of village constables and (*b*) the allotment of specified districts to the various missions, to prevent overlapping. The use of natives in government service originated with him: at his arrival not a single native was so used, but when he retired 20 per cent of the administrative expenditure went in pay for native services. His land regulations and those forbidding the issue of liquor and opium to natives helped materially to lay the foundations of Australian policy in Papua. He was awarded the founder's medal of the Royal Geographical Society for his explorations in the interior of New Guinea, and the Mary Kingsley gold medal 1910 for his labours in combating malarial fever in Lagos. In 1897 he published *British New Guinea, Country and People*, and his ten annual reports on British New Guinea are of the greatest value both to anthropologists and to philologists. (C.M.G., 1881; K.C.M.G., 1889; C.B., 1897; G.C.M.G., 1907; P.C., 1914.) L.A.

McIlwraith, SIR THOMAS (1835-1900), born at Ayr in Scotland on 17 May 1835 and educated at Ayr academy and the university of Glasgow, was trained to engineering and in 1854 migrated to Victoria and joined the engineering staff of the Victorian railways. In 1861 he dropped his profession to become a squatter in Queensland, and in October 1868 was sent to the legislative assembly by Maranoa. In 1874 he was for nine months minister for works and mines under Arthur Macalister (during two of those months he had his great rival Samuel Griffith as a colleague) but then abandoned politics for a few years. In 1878 he was returned for Mulgrave, challenged and defeated the Douglas ministry as soon as parliament met, and on 21 January 1879 formed his first ministry and entered on his long contest with Griffith. The outstanding episode of this term of office was his annexation of Papua (q.v.) which the British government disowned, thereby losing to Germany all the north-eastern coast of the island. In the same masterful spirit McIlwraith ratified over the head of parliament a contract for a direct mail-service between London and Brisbane via Torres Straits; but his attempt in 1883 to force assent to a railway on the land-grant principle from Charleville to the Gulf of Carpentaria was defeated, and he was ousted from office by Griffith. In 1888 he had his revenge, headed the poll for Griffith's constituency of North Brisbane, and formed his second ministry, which lasted only five months owing to a dispute with Governor Musgrave. Benjamin Kitt had been sentenced to three years' imprisonment for stealing two pairs of boots. McIlwraith and his cabinet wanted to release the man on probation; Musgrave refused, and, when the matter was pressed, insisted that it was one to be decided by the governor alone, offering at the same time to refer the whole question to the colonial office. McIlwraith persisted in his contention, and resigned office; the ministry was reconstructed under Boyd Morehead (q.v.), McIlwraith representing it in the legislative council without portfolio. In the end the colonial office decided (*a*) that a governor was bound to obtain the advice of his ministers before taking any action, (*b*) that, having received the advice, he might follow it or not as he thought fit, (*c*) that in this particular case Musgrave was within his rights, but 'would have exercised a sounder judgment if he had subordinated his personal opinion to the advice of his ministers.' In 1889 McIlwraith left Morehead on a minor question of finance (the amount of money to be spent on the Brisbane railway-station), and in August 1890 joined his old opponent Griffith in a coalition ministry which lasted until 1893 (McIlwraith taking the premiership when Griffith became chief justice), and was reconstructed as the Nelson ministry of 1893-8. In this McIlwraith was chief secretary and minister for railways, but failing health compelled him to retire in 1895. He refused the agent-generalship, settled in England, and died there on 17 July 1900.

McIlwraith's personality was his great asset; he was a big man with a 'bulldog' head, who always knew his own mind and could express his opinions forcibly and defend them doggedly. Moreover, he scorned details and minor issues, and was unhappy unless he had some unusual or grandiose policy to advocate. Such a man is fated, as McIlwraith was, to lead a party triumphantly until the last moment but one, when his followers suddenly discover themselves almost committed to schemes beyond the grasp of their imagination, and abandon the leader pell-mell. In a federated commonwealth he might have become the Cecil Rhodes of Australia. (K.C.M.G., 1882.)

McInnes, WILLIAM BECKWITH, born at Ringwood in Victoria in 1889, at the age of 14 entered the art school attached to the Melbourne gallery, and studied there under F. McCubbin and Bernard Hall until 1911. In 1912 he visited Europe to study and practise his art, extending his travels from the Hebrides in the north to the coast of Morocco in the south. Returning to Australia, he soon became known as a landscape painter, but gradually devoted the major part of his time to portraits, and in 1918 was made drawing-master at the art school where he had studied as a boy. He won the Archibald prize (see ARCHIBALD, JULES) for portraiture in 1921 and the three following years, and is represented in the Sydney, Melbourne, Brisbane, and Castlemaine galleries. W.M.

McKaeg, JOHN, of whose earlier years nothing is known, reached Sydney in 1831 and gathered a congregation of Baptist worshippers in a room rented for the purpose in King-street. This room being found too small, in 1832 he took a room in Hart's buildings in Pitt-street, and soon raised funds for building a church. In September 1832 McKaeg, accompanied by Ralph Mansfield (q.v.), Samuel Terry and Thomas Lawton, obtained from Bourke (then governor) a grant of the site in Bathurst-street on which the Baptist church now stands. Building materials were purchased, but the erection was delayed, and in 1834 McKaeg resigned his post. See BAPTISTS. J.C.

McKay, HUGH VICTOR (1865-1926), was born at Raywood, Victoria, on 21 August 1865, and educated at Drummarton state school. His early years were spent in farming on his father's property; at 18, having a special aptitude for agricultural work, he assumed full control of the farm. In 1884 he invented a harvesting machine which was an improvement on one devised by John Ridley (q.v.) in that it combined winnowing with stripping. This crude implement of McKay's, made from parts of other farm implements and a number of kerosene tins, aroused no enthusiasm, but he persevered, touring Victoria on a bicycle in the endeavour to overcome the conservatism of the 'men on the

land.' Eventually, in 1888, he was able to build a factory at Ballarat, and gradually overcame the indifference of the farmers and the opposition of other implement makers; his output increased, and the merit of his machine became acknowledged both at home and abroad. In 1906 he transferred his plant from Ballarat to Sunshine, near Melbourne, and during the next two decades the Sunshine Harvester Works grew to their present dimensions. There McKay had the satisfaction of seeing a wilderness slowly transformed into a model township with more than 4000 inhabitants, and the factory develop into workshops covering 35 acres. Over 2000 hands are employed, wages and salaries paid exceed £600,000 per annum, and the materials used are almost wholly of Australian production. Since labour and other conditions in Australia differ from those in older countries, McKay invented implements more suitable for the Australian farmer, so that, single-handed, he can do work that would elsewhere require assistance.

During the war he was a member of the Board of Business Administration associated with the defence department, and the Sunshine works were utilized for the manufacture of munitions; in 1918 he received the C.B.E. in recognition of his services to war industries. A charitable trust which he established for the improvement of conditions of life in the inland districts of Australia has an income of about £10,000 and is administered by three trustees. He died at Rupertswood, Victoria, on 21 May 1926. (C.B.E., 1918.)

Mackellar, Sir Charles Kinnaird (1844-1926), born at Sydney on 5 December 1844 and educated at the Sydney Grammar School, at first adopted a pastoral career, but in 1866 studied medicine at the university of Glasgow (M.B., C.M., 1871). Returning to New South Wales, he practised his profession until in 1882 he was appointed medical adviser to the government and first president of the board of health, which he organized. In August 1885 he was nominated to the legislative council, and in 1886-7 represented the Jennings ministry there as vice-president (February-December 1886) and minister for mines (December 1886-January 1887). In October 1903 he resigned his seat in the council and was elected by the New South Wales parliament to fill a vacancy in the Commonwealth senate caused by the resignation of R. E. O'Connor (q.v.); this appointment, however, lasted only to the end of November, when the federal parliament was dissolved, and Mackellar was renominated to the New South Wales council. In 1901 he sat on a commission that investigated the needs of neglected and delinquent children, and from that time onwards devoted himself to improving the methods by which the State dealt with them. From 1902 to 1914 he was president of the state children's relief board. He died at Woollahra, Sydney on 14 July 1926. (Kt. Bach., 1912; K.C.M.G., 1916.)

His daughter Isobel Marion Dorothea Mackellar, born at Sydney, has written three books of verse, *The Closed Door* (1911), *The Witch-maid* (1914), and *Dream-harbour* (1923), and three novels, *The Little Blue Devil* (with Ruth Bedford, 1912), *Outlaw's Luck* (1913), and *Two's Company* (with Ruth Bedford, 1914). When at her best Miss Mackellar must rank in the front line of Australian poets. She has feeling, fancy, a simple and frank choice of the fittest epithets, and a commendable directness of observation. Her 'My Country,' a simple and sincere patriotic poem, is known wherever there are Australians.

Mackennal, Sir Bertram, born in Melbourne on 12 June 1863, from an early age studied sculpture under his father and at the school attached to the Melbourne gallery. On the advice of an English sculptor, Marshall Wood, he migrated in 1882 to London and set up a studio with Charles Richardson, an Australian artist. For a time he studied at the art school of the Royal Academy; but in 1885 went to Paris; in 1886 returned to England to take charge of the art department of some potteries at Coalport in Shropshire. In 1887 he was commissioned to design and carve the panels on the front façade of the Victorian houses of parliament. After completing this and a few other commissions he went back to Paris in 1891, settled there, and in 1893 exhibited at the Salon the original model of the 'Circe' now in the Melbourne gallery; for this he was awarded a *mention honorable.* In 1894 he crossed to London and showed the 'Circe' at the Royal Academy. In 1901 and 1926 he revisited Australia.

Since 1894 he has exhibited regularly at the Academy, of which he was made an associate in 1909—the first Australian to be admitted—and a full member in 1922. The Chantrey bequest has placed in the Tate gallery 'Diana Wounded' and 'Earth and the Elements.' A South African war memorial by him is at Islington; Queen Victoria memorials at Lahore, Blackburn in Lancashire, and Ballarat; equestrian statues of King Edward VII in London and Calcutta; a memorial tomb of King Edward and Queen Alexandra in St. George's chapel at Windsor; and several statues of King George V at Delhi. His memorials of the war of 1914-18 stand (or will stand) in St. Stephen's hall at Westminster, in the playing-fields at Eton, and on the St. Kilda-road at Melbourne. 'The Horses of the Sun' are over the doorway of Australia House in London. His portrait statues or busts include those of Dame Nellie Melba, Sarah Bernhardt, and Marie Tempest. In Australia, besides the sculptures already mentioned, he is represented by a figure, 'Oceana,' in the Union Club at Sydney, a 'temple tomb' in Kew cemetery near Melbourne, a colossal head, 'War,' in front of the federal parliament-house at Melbourne (to be removed to Canberra when that town becomes the Commonwealth's capital), and a Shakespeare memorial in front of the Mitchell Library at Sydney. (M.V.O., 1912; K.C.V.O., 1921.)

Mackenzie, Sir Robert Ramsay (1811-1873), born at Coul in Ross-shire, Scotland, on 21 July 1811, in 1826 migrated to New South Wales and settled at Riddlesdale near Dungog. In 1837 he took over from E. G. Cory, his neighbour on the Williams, two New England stations between Walcha and Uralla, and a little later occupied land beyond Glen Innes; but his preference for city life, which left the stations to managers, led to heavy financial losses in 1844. In 1846 he made a rich marriage, transferred his activities to the Brisbane River valley, and became a wealthy squatter. In December 1859 Sir George Bowen picked him to be first colonial treasurer of Queensland (in the Herbert ministry), but after three years he resigned, objecting to Bowen's land policy and being too cautious to approve of his big-loan policy. In 1860 he was made chairman of the first board of education,

but in 1861 was rebuked by parliament for refusing to subsidize denominational schools, resigned the chairmanship at once to Macalister, and in 1862 left the board altogether. In February 1866 he rejoined the ministry—which was being re-formed under Arthur Macalister—as colonial secretary, but retired again when in July Herbert regained office for three weeks. He spent the next year in fighting Macalister, whom in August 1867 he ousted from the premiership; he then formed a ministry which passed the act adopting Sir J. Cockle's (q.v.) consolidation of the laws of Queensland. He also attained fame by postponing the deliverance of a ministerial statement because an eclipse of the sun was due. Defeated by Charles Lilley in November 1868, he within a month succeeded his brother in the baronetcy of Mackenzie of Coul. In 1871 he returned to Scotland, and died there on 19 September 1873.

Mackerels, fishes of the family Scombridae; several kinds occur in Australian waters, but the best known is *Scomber australasicus,* which is common on all the coasts south of the tropics. It is a small fish, rarely exceeding 14 inches in length, and sometimes moves along the coasts in great shoals, pursued by larger fishes and dolphins. In endeavouring to escape from its enemies, it swarms into inlets and harbours, where it is captured by line fishermen. Though apt to decay rapidly (especially if the flesh be not well bled), a fresh mackerel is not to be despised as a food-fish. The Australian species is very closely allied to the Chub Mackerel, Spanish Mackerel, or Thimble-eyed Mackerel (*Scomber colias*) of European and American seas. Another species, *Rastrelliger kanagurta,* is widely distributed in the Indian and Pacific oceans, and has been recorded from tropical parts of Australia.

Fishes of the genus *Scomberomorus,* called in Australia 'Spanish mackerel,' are esteemed both as game and food-fish, attaining a length of about six feet. They are compressed and slender in form, and beautifully marked with dark bars and spots on a silver ground. In Queensland, where they are commonly called 'kingfish,' they are captured with a large hook concealed in a bright-coloured rag and trailed behind a boat on a strong line. They are also eagerly sought by rod-fishermen, who use fine lines and troll behind a launch a garfish beset with many small hooks. Three or four distinct species of Spanish mackerel are known from the Australian coasts, all inhabitants of open tropical waters, though some periodically extend southward as far as Sydney.

The Frigate Mackerel (*Auxis thazard*) and the Horse Mackerel (*Sarda chiliensis*) are other members of the group, and range over the open oceans. They have torpedo-shaped bodies and large forked tails, which enable them to travel through the water with great speed. They occasionally appear in schools along the coasts, but little is known of their habits in Australia.

A.R.McC.

McKinlay, JOHN (1819-1872), born at Sandbank on the Clyde in 1819, came to New South Wales in 1836 to join his uncle on a sheep-station, and ten years later settled at Ki on the Murray in South Australia. Here he began to explore the unoccupied country lying between the Darling and Lake Torrens, and later took up several runs in that area; he also induced the colonial government to recognize the Murray River as an important highway of trade. In 1861, when anxiety was felt as to the fate of Burke and Wills, he was chosen by the government to lead the search party which left Adelaide on 16 August (see EXPLORATION BY LAND). He discovered traces of Burke and Wills, and found the remains of Gray. On his return 13 months later the South Australian parliament made him a grant of £1000, and in May 1863 the Royal Geographical Society of England presented him with a gold watch. In 1865, B. T. Finniss (q.v.) having failed to convince the South Australian government that Escape Cliffs on Adam Bay was a suitable site for the capital of the Northern Territory, McKinlay was sent to investigate the area between the Adelaide, Liverpool, and Roper rivers in the hope of finding an inland site for the capital. Unfortunately he did not reach Adam Bay until 5 November, had to traverse swampy country in an exceptionally wet season, and with difficulty reached the East Alligator River, from the mouth of which he returned to Adam Bay on a raft covered with the skins of his horses and provisioned with their flesh. Disheartened by this failure, he returned to South Australia, settled on a farm near Gawler, and died there on 31 December 1872.

Maclagan, E. G. S. See SINCLAIR-MACLAGAN, E. G.

MacLaurin, CHARLES (1872-1925), son of Sir H. N. MacLaurin (q.v.) was born in Sydney on 22 November 1872 and educated at the Sydney Grammar School and the university of Edinburgh (M.B., Ch.M., 1895; F.R.S.C. Edin., 1910). On his return to Australia in 1898 he was attached to the Royal Prince Alfred hospital (in which he eventually became senior honorary surgeon), and in 1911 made lecturer in clinical surgery at the university of Sydney. In 1915 he went to England as lieutenant-colonel in command of the Australian auxiliary hospital at Wandsworth, and afterwards to the front as surgeon-specialist to No. 2 Australian Casualty Clearing Station. In 1917 he was invalided back to Sydney, and was surgeon-specialist to Randwick military hospital until the end of the war. In 1922 he published *Post Mortem,* a series of historical sketches dealing with the pathology of famous men and women after a fashion previously adopted only by French medical experts. His second book, *Mere Mortals* (1925, published posthumously), is of the same *genre.* He died at Rose Bay near Sydney on 19 April 1925.

L.G.D.

MacLaurin, SIR HENRY NORMAND (1835-1914), born at Kilconquhar in Fifeshire in 1835, and educated at the universities of St. Andrews and Edinburgh (M.D., 1857), joined the navy in 1858 as assistant-surgeon and served at Athens during the revolution of 1862. Later he was medical officer at Greenwich Hospital, but retired from the navy in 1871, migrated to New South Wales, and settled in Sydney. In 1883 he was elected a fellow of the university senate, in 1885 appointed chairman of the board of health and of the immigration board, and in 1889 nominated to the legislative council; in 1893-4 he represented the Dibbs ministry in that house. He was also a director of the Bank of New South Wales, and a trustee of St. Andrew's College within the university, and of the Royal Prince Alfred hospital. But his chief work was done for the university, of which he was vice-chancellor in

1887-9 and 1895-6, and chancellor from 1896 until his death on 24 August 1914. He took charge of university affairs at a critical stage in its history, when the government had considerably reduced the subsidy and was threatening to withdraw it altogether unless the department of education was given a much greater share in its control. He averted this danger, managed the Challis bequest (see CHALLIS, J. H.) so adroitly as to put university finance on a sound footing, and by his influence with political leaders secured fresh grants both for new professorships and buildings and for the general work of the institution. (Kt. Bach., 1902.)

MacLaurin, HENRY NORMAND (1878-1915), son of Sir H. N. MacLaurin (q.v.), was born at Sydney on 31 October 1878, educated at Sydney Grammar School and the university of Sydney (B.A., 1899), and called to the New South Wales bar in 1904. Joining the New South Wales forces, in 1899 he was appointed 2nd lieutenant (lieutenant, 1900; captain, 1903; major, 1908; lieutenant-colonel, 1913; colonel, 1914; brigadier-general, 1914). In 1913 he had been promoted to the command of the 26th infantry regiment (citizen forces) when, on the outbreak of the war in 1914, he was selected by General Bridges to train and command the 1st (New South Wales) infantry brigade. The appointment was almost experimental, MacLaurin being only 35 and comparatively untried; but his magnificent moral qualities enabled him to rise completely to the occasion. At the landing on Gallipoli, 27 April 1915, a few hours after relieving Colonel Sinclair-Maclagan (q.v.) and the tired staff of the 3rd brigade, both MacLaurin and his brigade-major, Irvine, while organizing resistance to an enemy counter-attack, were shot from the rear by Turkish snipers. Although the A.I.F. thus early lost an officer whom it recognized as the beau-ideal of Australian manhood, his influence among his subordinates was clearly discernible to the end of the war. It was several weeks after MacLaurin's death that an order was promulgated promoting a number of A.I.F. colonels, including MacLaurin, to the temporary rank of brigadier-general. He was therefore only known to the A.I.F. as colonel. See AUSTRALIAN IMPERIAL FORCE. C.E.W.B.

Maclay, N. DE M. See MIKLUHO-MAKLAY, N. N.

Macleay, ALEXANDER (1767-1848), head of a family that figured largely in the history of New South Wales for 50 years, was born in Ross-shire, Scotland, on 24 June 1767 and educated for commerce, but in 1795 joined the British civil service as chief clerk to the prisoners-of-war board, and from 1806 to 1818 was secretary to the transport board. In 1825, when the friction between Brisbane and his secretary Frederick Goulburn made it necessary to recall both of them, and Darling's reputation as a martinet seemed to indicate him as a suitable successor to Brisbane, Bathurst chose Macleay for the new governor's adviser, both for his common sense and for his experience of transport conditions, and persuaded him to take the secretaryship. Appointed to the legislative council on 20 December 1825, before he reached the colony, he assiduously carried out the constantly increasing duties of his office under Darling and Bourke from 7 January 1826 to 31 December 1836; he then retired from official life on his pension as ex-secretary of the transport board, but in 1843 was elected to the new legislative council by the counties of Gloucester, Macquarie, and Stanley (i.e. the north-coast district), and was made speaker. He retired from public life on 19 May 1846, and died on 19 July 1848.

Macleay's administrative and political work constituted only a fraction of the service he rendered to the colony. In 1794 he had become a fellow of the Linnean Society—then only six years old—and held its secretaryship from 1798 to 1825; the Royal Society made him a fellow in 1809 and a councillor in 1824, and several learned societies in foreign countries admitted him to membership. His special hobby was entomology, and in 1825 he was said to have the finest private collection of insects in existence. This collection—in making which he came into close relations with J. W. Lewin (q.v.) over some new Australian species—he brought almost intact to Australia, and it formed the nucleus of the great Macleay collection now in custody of the university of Sydney. But he also took an interest in ornithology, and made the Linnean Society many presentations of South American and Australian bird-skins both before and after his arrival in New South Wales. The residence of such a man in a colony that lacked almost every kind of scientific organization and equipment and had few learned men among its inhabitants, was of great value both as a stimulus and for the actual researches he instigated and undertook. He was possibly the first (in an article signed 'U' and published on 1 January 1828) to suggest the establishment of a museum, and certainly in 1832 formed a 'colonial museum' and procured for it an endowment of £200 a year. He was also the first president and staunchest friend of the Australian Museum from its incorporation in 1836, and was for many years president of the Australian Subscription Library. Residing at first in Sydney (the site of his house is now occupied by Loftus-street, between the lands and education departments), he received two grants of land, one of 54 acres at Elizabeth Bay, the other 2500 acres near Ulladulla; the first he made a nursery for rare trees, shrubs, and plants from all parts of the world—Joseph Hooker described it as a 'botanist's paradise'—and his use of the second for farming and stock-breeding was much praised by Darling; a block of 15,000 acres near Camden, which he bought in 1827, was similarly developed and used for experiments in horticulture and fruit-growing. His encouragement of exploration led to the naming after him of an island, a range of hills, and two rivers; and his botanical enthusiasm was commemorated by Robert Brown (q.v.) in the generic name of a poppy (*Macleaya cordata*) which has unfortunately been since re-absorbed in *Bocconia*.

He himself usually spelt his name McLeay; the forms M'Leay and MacLeay also occur. To prevent confusion, the spelling which was adopted by his son and nephew is here used for the whole family.

Of his 17 children two deserve special notice. WILLIAM SHARP MACLEAY (1792-1865), his eldest son, born in London on 21 July 1792 and educated at Westminster School and Trinity College, Cambridge (B.A., 1814; M.A., 1818), entered the diplomatic service and was for a time stationed in France, where he met Cuvier and other naturalists. From 1825 to 1836 he was stationed in Cuba to administer matters

connected with the abolition of the slave-trade; then, returning to England and retiring from the civil service, he was elected to the councils of the Linnean and Zoological societies and of the British Association for the Advancement of Science; about this time he discussed with Charles Darwin the publication of the results of the *Beagle's* voyage. Towards the end of 1838, partly to study Australian insects and partly because the English climate was too rigorous for him after so many years in the West Indies, he joined his father in New South Wales, reaching Sydney in March 1839. Here he busied himself with the collection of insects (to which he added P. P. King's specimens from northern and north-western Australia), the care of the Elizabeth Bay garden, and investigations into the local marine fauna. He was a trustee of the Australian Museum (1853-1862) and for some time a member of the national board of education. His published scientific work belongs mainly to the period before 1839. He had a gift for friendship, and knew intimately all the scientifically minded Australian visitors or residents of his day, among whom the two most notable were T. H. Huxley and Robert Lowe. He died on 26 January 1865.

Another son, Sir George Macleay (1809-1891), born in London and educated at Westminster, followed his father to New South Wales in 1827, and lived most of his Australian life at Alexander's Brownlow Hill farm near Camden, which after the father's death was left to him. His vigorous youth expressed itself largely in exploration, and in 1829 Sturt asked for him as a companion on the famous expedition to the mouth of the Murray; Macleay took his full share of the many hardships, and the friendship thus established was unbroken till Sturt's death in 1869. After his father's death George Macleay was elected to the legislative council by the Murrumbidgee electorate (1851-6), was a member of two committees on the constitution, and represented the same constituency in the legislative assembly in 1856-9, being in the latter year succeeded by his cousin William. Returning to England, he settled in Surrey, and for 30 years devoted himself to horticulture and the entertainment of Australian friends and men of science, returning to Australia for only a short visit—to settle the affairs of William Sharp, whose heir he was—in the early seventies. In 1869 he was given the C.M.G.—apparently a belated recognition of his share in Sturt's explorations, since it had been intended at the same time to give Sturt (who died on 16 June of that year) the knighthood of the same order. He died at Mentone, France, on 24 June 1891. (C.M.G., 1869; K.C.M.G., 1875.)

A trustworthy account of the family is J. J. Fletcher's presidential address to the Linnean Society of New South Wales, published in the society's *Proceedings* for 1920; for W. S. Macleay, Patchett Martin's *Life and Letters of Robert Lowe* should also be consulted, and for Sir George Macleay, Mrs. N. G. Sturt's *Life of Charles Sturt.*

Macleay, Sir William John (1820-1891), nephew of Alexander Macleay, was born at Wick in Caithness-shire on 13 June 1820, educated at the university of Edinburgh, and trained for the medical profession; but, his widowed mother dying when he was 19 years old, he was induced by his uncle to come to Australia, and reached Sydney with his cousin W. S. Macleay in March 1839. He took up sheep-farming, at first near Goulburn, later at Kerarbury on the Murrumbidgee, and for 15 years was known only as a successful breeder. In 1855, taking to politics, he was elected to the council by the pastoral districts of the Lachlan and lower Darling. When the new constitution came into force, the same constituency returned him to the assembly for the period 1856-9; in 1859 he succeeded his cousin George as member for the Murrumbidgee, holding the seat continuously until November 1874, when he resigned to undertake an expedition to New Guinea. On his return he was in October 1877 nominated to the legislative council, and remained a member till his death on 7 December 1891. He himself did not in later life use the name John, preferring to be known as William Macleay.

In 1863 he was chairman of a committee of the assembly on the defence of Port Jackson. In December 1864 he distinguished himself by his courage in repelling an attack of the bushrangers Gilbert, Hall, and Dunn at Plumb's Inn near Goulburn, and was one of the seven to receive as official recognition in 1875 a gold medal 'for gallant and faithful services' rendered during the bushranging epoch. An indefatigable worker in the cause of railway construction and inland communication, he had the satisfaction of being present in September 1878 at the opening of the railway to Wagga. He is best known as an entomologist, icthyologist, and patron of science. In 1875 he organized the *Chevert* expedition to investigate the fauna of New Guinea and the Torres Straits, and thus acquired a vast collection of specimens in all departments of natural history. He contributed to scientific journals numerous papers on Australian Coleoptera, and in collaboration with Dr. H. G. Alleyne published 'The Fishes of the *Chevert* Expedition.' His *Descriptive Catalogue of Australian Fishes* was of economic importance. For it he received a gold medal from the International Fisheries Exhibition in London; it also won him in 1880 the chairmanship of a commission to enquire into Australian fisheries, which resulted in the fisheries' act of 1881, still in force. The Macleay natural history collection, afterwards presented to the university of Sydney and housed in the Macleay Museum, was in part inherited from Alexander and W. S. Macleay, but was greatly enlarged by continual purchase of specimens and by the regular employment of professional collectors. Its value lies in its extensive representation of the Australian fauna. To this benefaction he attached an endowment of £6000 to pay the salary of a curator. In 1862 he founded the Entomological Society of New South Wales; it lapsed in 1873, but the next year its more comprehensive successor the Linnean Society of New South Wales (see Societies, Learned) was founded, and carried on chiefly through Macleay's generosity. When its library and effects were destroyed in the garden palace fire, Sir William largely replaced the library, and in 1885 gave the society land and a building, supplemented by an endowment of £20,000. Among his other benefactions were £12,000 for bacteriological research and £35,000 for the foundation of four research fellowships of £400 per annum in biology or geology—known as the Linnean Macleay fellowships, tenable by bachelors of science at the university of Sydney. For many years he was a trustee of the Australian Museum. (Kt. Bach., 1889.)

MacMahon, Sir Charles (1824-1891), son of an Irish master of the rolls, was born near Dublin on 11 July 1824, entered the army in 1842, saw service in Canada with the 71st light infantry and in India with the 10th hussars, retired with the rank of captain in 1851, served a short time in the Royal Irish Constabulary, and in 1852 migrated to Victoria, where next year he was made assistant-commissioner of police. In 1854 he became chief commissioner, but resigned in 1858 on account of a quarrel with the premier, O'Shanassy, and entered politics in 1861 as member for West Bourke. Curiously enough, he almost immediately became a minister without portfolio in O'Shanassy's ministry of 1861-3; but, although he represented the same constituency for another 20 years almost without a break (1866-78, 1880-6) he never again held office. From 1871 to 1877 he was speaker of the assembly; charged by Berry with undue favouritism to the McCulloch ministry of 1875-7 (during the notorious 'stonewall' and 'iron hand' episodes), he was rejected in 1877, but was replaced for a few months in 1880 when James Service was in office. He died at East Melbourne on 23 August 1891. (Kt.Bach., 1875.)

McMillan, Angus (1810-1865), born in Skye in 1810, migrated to Australia and landed in Sydney on 23 January 1838, and found employment on the sheep-station of Lachlan Macalister near Goulburn. Early in 1839 Macalister despatched McMillan 'to look out for stations' in the unknown region south of Monaro. Starting from Currawong on the Snowy River on 28 May 1839, he worked down the Snowy almost to Buchan, but was then forced to turn to Omeo, which had already been occupied. By the end of the year, however, he was settled on the Tambo, and in January 1840 forced his way down that river to the coast and traversed the Gippsland lake area as far as the Macalister and Latrobe rivers. A second journey in July took him no farther, but a third in October-November traversed the southern ranges to Tom's Cap; his next attempt, in February 1841, took him to Port Albert, and thus opened up a practicable route from Monaro to the sea, along which drays followed him in May. On the strength of this achievement he is always recognized as the discoverer of Gippsland (which, by the way, he called Caledonia Australis), although Strzelecki (q.v.), following his tracks in 1840 to the Macalister and thence striking south-west across the Thomson and Latrobe and encountering insurmountable difficulties in the ranges beyond, had by May 1840 extricated himself near Western Port and so reached Melbourne. It was, however, the fertile country of northern Gippsland and the track to Port Albert, with its facilities for shipping cattle, that the squatters desired, not the difficult ranges of Strzelecki's finding; so that, while the Polish traveller imposed his names on the map, the Scot remained hero of the adventure. After a good deal of nomadic squatting McMillan settled down at Bushy Park on the Avon, became protector of the local aborigines, and entered the Victorian assembly as the first representative of Southern Gippsland. In November 1864 he was asked by the government to open up tracks from Crooked River (near Dargo) to Omeo and Harrietville, and had completed 200 miles of them when illness overtook him and he died at Iguana Creek on 18 May 1865.

Maconochie, Alexander (1787-1860), born in 1787, entered the navy at the age of 15 and received his captaincy before the close of the Napoleonic wars. In 1836, while secretary to the Royal Geographical Society, he was invited by Sir John Franklin (q.v.) to accompany him to Tasmania as private secretary; they reached Hobart early in 1837. Before leaving England, Maconochie had been asked by the Society for the Improvement of Prison Discipline to report to them on the operation of the convict system; this request was officially approved on the understanding that communications should pass through the colonial office. In May 1837 Maconochie began to formulate an attack on the assignment system (q.v.) on the ground that under it punishment was uncertain, unequal and almost without exception demoralizing; he proposed to substitute for it the direct control of prisoners by official superintendents trained to develop a reformatory and social system of discipline—a somewhat sketchy proposal which he later developed into the 'mark system' explained under Convicts. Franklin submitted this report to men with much Tasmanian experience, and their comments were for the most part unfavourable; their evidence was forwarded to London in October, and printed in April 1838 as a parliamentary paper, *The Present System of Convict Discipline in Van Diemen's Land.*

Meanwhile Maconochie had interested himself also in the fate of the aborigines, suggesting to Bourke and the colonial office that they should be enlisted in the public service (especially in the constabulary), their families being encouraged to settle in native villages under government protection. Bourke was so much impressed by the scheme (which had already been tried on a small scale in Flinders Island) that he introduced it in a modified form in the Port Phillip district, and later in the year the colonial office recommended it to Gipps (see Black Trackers). In 1838, however, Maconochie, having alienated Franklin by his extreme attitude on convictism and his open attacks on local officials, was dismissed from office. He devoted his enforced leisure to a systematic development of his proposals, and in 1839 published in Hobart *Australiana: or Thoughts on Convict Management,* followed by *General Views regarding the Social System of Convict Management.* Meanwhile his earlier report had reached a wide public in England and considerably influenced the select committee of 1837-8 on transportation—which recommended that 'the mode of governing them (convicts) lately suggested by Captain Maconochie might in part at least be attempted with advantage.' When, owing to the pressure of public opinion the British Government decided to try out reforms on Norfolk Island, Maconochie was the obvious instrument; but the actual choice was left to Gipps, who consulted Franklin and obtained his approval of Maconochie's appointment.

The story of Maconochie's work at Norfolk Island in 1840-44 is told under Convicts. When he was relieved of office in 1844, he returned to England to open a long struggle with the home office and local authorities, who were wedded to the system of cellular isolation. 'Human nature' he wrote 'is not improved by being broken across.' In 1846 he published *Crime and Punishment,* which caused considerable stir among penologists; this was followed by a series of pamphlets dealing with his work at Norfolk

Island or explanatory of his ideas. In 1848 he published a pamphlet, *Emigration, with advice to Emigrants*, in which he endeavoured to prove the fallacy of the Wakefield system of colonization. In October 1849 he was appointed governor of the new Birmingham gaol, and was permitted to introduce the 'mark' system among the juveniles. But the assistant-governor, who had influence with the visiting justices, disapproved of his leniency; it was further said that he gave too much time to promulgating his theories and not enough to the details of administration, and in October 1851 he was forced to resign. He figured prominently during the proceedings of a royal commission appointed two years later to inquire into charges made against his successor, on the findings of which was based Charles Reade's *It's Never Too Late to Mend*. Despite great pecuniary loss and disappointment, Maconochie remained an indefatigable pamphleteer in the cause of prison reform. He did not, however, again hold office, and died at Morden in Surrey on 25 October 1860. (K.H., 1836.) See CONVICTS and NORFOLK ISLAND.

Macquarie, LACHLAN (1761-1824), born on 31 January 1761 on the island of Ulva near Mull in Argyleshire, was the eldest son of Lauchlan Macquarrie, 16th chief of the clan Macquarrie, who entertained Dr. Johnson during his tour of the Hebrides. Young Lachlan —who seems to have been responsible for dropping both the 'u' of his first name and the second 'r' of his surname—entered the army on 9 April 1777 (ensign, 1777; lieutenant, 1781; captain, 1788; major, 1796; lieutenant-colonel, 1802; colonel, 1810; major-general, 1813), and served with the 84th regiment in Nova Scotia and the 71st in New York and Charleston during the war of the American revolution. At the close of the war he was sent to Jamaica, and in 1784 placed on half-pay. In 1787 he was appointed to the 77th regiment on condition of raising 15 recruits for it (he managed to obtain 17). Leaving England on 28 March 1788 for India with his regiment, in Cape Town he met William Bligh—then on his way to Tahiti in the *Bounty*—and took him aboard the troopship for dinner and dancing. In India he saw active service against Tippoo Sahib at the sieges of Cannanore (1790) and Seringapatam (1791); also in the Dutch settlement of Cochin on the Malabar Coast (1795), in Ceylon (1796)—where he was given separate command—and at the second siege of Seringapatam in 1799. In 1793 he married Jane Jarvis, daughter of the chief justice of Antigua, but she died in 1796 and left him for many years disconsolate. In 1800 he was made deputy-adjutant-general to David Baird, who had been given command of an expedition designed to co-operate with Sir Ralph Abercromby in driving the French out of Egypt; in February 1801 he left India, crossed Egypt from the Red Sea to the Nile, sailed down to Cairo, and arrived just in time to witness the capitulation of Alexandria. After returning to India in July to become military secretary to Jonathan Duncan, governor of Bombay, Macquarie went back to England early in 1803, was given the assistant-adjutant-generalship for the London district, and bought back a family estate on Mull which his father had been forced to sell to pay his debts. Anxious for once to remain at home —for he was in 1805 busily wooing the lady who became his second wife and gave her name to Mrs. Macquarie's Chair in the Sydney Domain —he appealed to both civilian and military authorities to be permitted to stay in London; but neither 'bad health' nor 'urgent private affairs' availed him, and in April 1805 he sailed for Bombay, nominally to rejoin his regiment (the 86th), but really to act once more as military secretary to Jonathan Duncan. By October 1807 he was back in London, after an overland journey from the head of the Persian Gulf across Persia, Armenia, and Russia. Meanwhile he had exchanged into the 73rd regiment, and had been gazetted its lieutenant-colonel as far back as 30 May 1805; after his marriage on 3 November 1807 he settled down at Perth, where the regiment was stationed.

In 1808 the news of the Bligh mutiny caused great searchings of heart at the colonial office, and Castlereagh (who then controlled the office) determined to substitute for the naval governors, always at loggerheads with a pseudo-military garrison, a series of military governors supported by their own regiments. To initiate this scheme he chose Colonel Nightingall, the commanding officer of the 73rd, and on 22 December 1808 Macquarie received orders to get the regiment ready for an early embarkation at Portsmouth. When in April 1809 Nightingall fell seriously ill and was compelled to resign his appointment, Castlereagh decided that the least embarrassing change would be to offer the post to Nightingall's next-in-command. On 8 May, therefore, Macquarie received his commission as governor and the local rank of colonel in New South Wales, sailed from England on the 22nd, and on 28 December reached Port Jackson. It is typical of the times that, although he anchored in Watson's Bay at 9 a.m. on the 28th, he did not reach Sydney Cove until the evening of the 30th, landing next day, and taking over control from Colonel Paterson on 1 January 1810.

To impress on the population the fact that mutiny and irregular government were at an end and the rule of law restored, Macquarie made this an occasion of much ceremony. His commission as governor was read at noon 'in the presence of all the inhabitants, with all due form and solemnity,' the 73rd and 102nd regiments (his own and the New South Wales Corps) being drawn up in a square at the meeting-place; in the evening there were bonfires and other illuminations. The impression made was good, and from that time forward 'due form and solemnity' accompanied the new governor's movements.

Macquarie's first despatch, penned nine weeks after his arrival, foreshadowed one side of his administrative activities. Insufficient accommodation, he wrote, compelled him to commence building barracks to hold 1000 men; a new general hospital was needed, as well as granaries, stores, and barracks for convicts; a surveyor-general and a competent architect should be sent out as soon as possible. Public buildings were evidently an important part of his schemes for the colony. A few months later he began town-planning. He divided Sydney into five districts, with a watch-house in each; the principal streets were to be 50 feet wide; he renamed them, and caused boards bearing the new names to be set up. Further, he laid out a market square in a central position, marked out a reserve, to be named Hyde Park, for recreation and amusement, and set apart as a common for grazing purposes the land which is now Centennial Park.

He next proceeded to inspect as much of the inland settlement as was at that time accessible. On 6 November 1810 he rode off at 6 a.m. to the upper part of George's River, inspected the farms there, and took a boat to examine the country along the river-banks. There and then he marked out the site of a new township to be called Liverpool after Lord Liverpool, then British prime minister. Bankstown, Botany Bay, Parramatta, Baulkham Hills, Menangle, and the Cowpastures on the Nepean were visited successively. Down the Nepean Macquarie journeyed to its junction with the Grose (which makes it the Hawkesbury), settled the sites for Windsor, Richmond (which he named), Pitt Town, and Wilberforce. On 10 December he was back at Castle Hill inspecting the government farm there, and returned to Sydney after 37 days' travel over practically the whole of the colony's hinterland. No governor before or since has displayed such energy and persistence in making himself acquainted with the country.

In 1811 Macquarie crossed Bass Strait and visited Hobart, the voyage occupying 19 days on account of stormy weather. At Hobart he settled the sites of new military barracks, a military hospital, a new general hospital, and a county gaol; named all the streets—calling the principal thoroughfare after himself—and caused signboards to be set up defining the limits and direction of each street.

His longest and most important journey was carried out in 1815, over the road made under his instructions by William Cox (q.v.) of Windsor. Most of the resounding names bestowed by him upon the ranges, rivers, and plains that he passed *en route* have gone into oblivion, but Mount York remains, and the Macquarie River, and the Lachlan River which Evans discovered shortly afterwards.

His many journeys familiarized him with the conditions prevalent in all parts of the settlement, and he was not slow to improve them where possible. The settlers on the Hawkesbury he helped through difficulties, first with floods and then with blackfellows. Those of them, on the other hand, who took advantage of the rough hill-country beyond to indulge in illicit distilling, and their accomplices who smuggled the raw spirits into Sydney, he pursued with the utmost rigour. Exploration he encouraged persistently, and his road-making and bridge-building were worthy of a Roman proconsul; the 276 miles of public road constructed during his governorship are evidence of his far-sightedness. See EXPLORATION BY LAND.

With the aborigines he first tried peaceful persuasion. With a strange lack of humour he had posted up on trees in the bush a proclamation addressed 'To the Black Natives,' which stated that their custom of assembling near the British settlements and there fighting and inflicting injuries upon each other was intolerable and inimical to British civilization. It added that, unless they desisted, they would be severely punished, and that further attacks upon white settlers would meet with retribution. This extraordinary proclamation was signed by John Thomas Campbell, secretary to the government. As the blacks took no notice, Macquarie despatched against them three military detachments, with white settlers and friendly natives as guides, to the Cowpastures and the regions beyond Liverpool and Windsor, with instructions to clean up the whole country from the Kurrajong to the Illawarra. After a month the expeditions returned with a number of prisoners, including four small black children (two boys and two girls); with these Macquarie founded a school for aboriginal children at Parramatta, but at the annual muster of blacks at Parramatta returned them to their relatives.

The settlers on the Hawkesbury gave much provocation to the blacks. Many who were emancipists were lazy, improvident, and addicted to drink, and the high prices for rum charged by Macquarie's contractors for Sydney hospital (see HOSPITALS) gave an impetus to the manufacture of 'moonshine' in the Hawkesbury ranges. One result was that wanton attacks were frequently made by drink-maddened settlers upon the neighbouring aborigines, and their reprisals—justifiable though they were—led to punitive expeditions against them by Macquarie's orders.

In his treatment of the convicts, who formed such a large part of the population, Macquarie found himself in conflict with the justiciary, the magistrates, the chief officials, and the free inhabitants of the colony. He held that, when the criminal had purged his offence, he should be allowed an opportunity to build up his life anew. Accordingly he went on board every convict transport as it arrived and delivered a homily, in which he explained to the transportees that their former misdeeds would not be remembered against them in this new country, and that it depended upon themselves to remake their lives. Hardened criminals scoffed at the exhortations, and took advantage of the exhorter whenever possible.

In order to secure labour for his building and town-planning schemes he kept numbers of prisoners in Sydney and in the other towns that he founded. In particular he retained the services of almost all the skilled mechanics, to the great chagrin of the free immigrants who wanted skilled labour to develop their land-grants. Moreover, the officials and the free immigrants drew between themselves and the convicts an impassable line which Macquarie flatly refused to recognize. It was a fixed principle with him that men whose sentences had expired, or had been remitted for good conduct (emancipists, q.v.), should be helped to forget their past. He extended the hospitality of government house to such men as James Meehan (q.v.) and William Redfern (q.v.), both men of education and talent. Meehan became assistant surveyor-general, accompanied Macquarie on most of his inland journeys, and was a constant guest at government house. Redfern became Macquarie's family physician. The governor's habit of inviting these emancipists to his table caused many 'exclusives' to refuse his invitations, and when in 1819 John Thomas Bigge (q.v.) came out to report to the colonial office on Macquarie's administration, he was scandalized to find that he was expected to sit at the same table with persons who had worn the broad arrow.

Andrew Thompson, a settler on the Hawkesbury, had been transported for setting fire to a stack, had served out his sentence, and grown wealthy as a government contractor, trader, and money-lender. In the first year of his governorship (1810) Macquarie made Thompson chief magistrate for the Hawkesbury. The appointment was hotly resented by the free population. Thompson died in the same year, and Macquarie on hearing of his decease wrote of him as 'an

excellent worthy man and much and justly regretted by every one.' Then it was learned to the amazement of the public that Thompson had left one-fourth of his fortune (which was estimated at £25,000) to the governor—'a most extraordinary instance of friendship and gratitude,' comments Macquarie. Bigge, however, although he censured the governor's administrative conduct severely, expressly reported that he found no trace of corruption in any of Macquarie's actions, and that no breath of suspicion in that regard affected his reputation. For Macquarie's attempt to force the supreme court to admit convict attorneys to practice before it see BENT, ELLIS. Earl Bathurst in 1817 administered a mild reproof, which Macquarie's proud spirit could not brook. He tendered his resignation; Bathurst immediately reassured him and begged him to withdraw it. Unfortunately that letter did not reach its addressee—the post-office was not incorruptible in those days, and it is at least conjecturable that the letter was impounded in transit by some agent of one of the governor's numerous enemies.

In the same year (1817) a certain William Blake, with several others (all of very doubtful character and engaged in very questionable practices), was arrested by soldiers of Macquarie's bodyguard as a trespasser in the private grounds of government house. Macquarie sent the offenders to a magistrate, who sentenced the women to a short term of imprisonment and the men to a dozen lashes apiece. Blake protested that he was a free settler and that it was contrary to the principles of British justice that a free man should be flogged for trespassing. Macquarie refused to interfere with the sentence, and Blake was flogged; he took his tale to Samuel Marsden and Jeffery Hart Bent, who advised him to go to England and present a memorial to Earl Bathurst (they also supplied the funds for his journey). Blake's complaints seem to have been the 'last straw' on the back of the colonial office, which promptly sent out Bigge. Bigge's reports, when they appeared, were on the whole adverse to Macquarie, emphasizing particularly his excessive expenditure on public works (Bigge had no great belief in the colony's future), his attitude to emancipists, and his handling of the 'rum' traffic. But long before these reports had reached London the governor's fate was decided. The non-receipt of any answer to his proffer of resignation in 1817 deeply wounded Macquarie's pride. In February 1820 he told Bathurst of 'the regret and mortification I feel at your Lordship's not condescending even to notice the receipt of my Letter of Resignation,' and again urged that he should be allowed to retire from a situation in which he had been harassed and calumniated beyond endurance. In July Bathurst gave him the long-desired leave, and in November let him know that Sir Thomas Brisbane had been chosen as his successor. Macquarie's acknowledgment in March 1821, emphasizing 'the many indignities and mortifications I have experienced for the last Eighteen Months,' betrays his real feelings about Bigge—whom, curiously enough, he had at first admired for 'his very gentlemanly manners and polite address.' On 1 December the retiring governor handed over his charge to Brisbane, and in February 1822 left Port Jackson in the ship *Surry* for England, where he lived quietly in London until his death on 1 July 1824. His diaries (which are especially voluminous for the period of his Australian governorship), and a mass of memoranda covering the greater portion of his life, are in the Mitchell Library at Sydney.

Macquarie's foibles, and his entire disregard of other people's personal feelings when he felt himself justified in rebuking them, have done his reputation great harm. No man could incur the enmity of Marsden, Bent, and Bigge and escape unscathed. But John Macarthur, who disliked as much as anyone Macquarie's emancipist policy and had no special reason to love him, told a disgruntled official at the colonial office:—'Governor Macquarie is a gentleman in manners, human and friendly to all . . . a man of unblemished honor and character altho' it may not have been his lot to do that which I think no man ever will do—to give satisfaction to all.' Macquarie's habit of attaching his own name to various places and buildings has been much jeered at, but greater men have had worse foibles, and he made his friends and best officers eponyms too; it may be added that the Lachlan River and other Lachlans commemorate his young son, not himself.

Foibles and mistakes, however, are far outweighed by the active excellence of his personal rule. In the proud *apologia* for his administration which he addressed to Bathurst on 27 July 1822 he set forth a few of his claims to the gratitude of the colony and of Britain:—

> I found the Colony barely emerging from infantile imbecility, and suffering from various privations and disabilities; the Country impenetrable beyond 40 miles from Sydney; Agriculture in a yet languishing state; commerce in its early dawn; Revenue unknown; threatened by famine; distracted by faction; the public buildings in a state of dilapidation and mouldering to decay; the few Roads and Bridges, formerly constructed, rendered almost impassable; the population in general depressed by poverty; no public credit nor private confidence; the morals of the great mass of the population in the lowest state of debasement, and religious worship almost totally neglected.

He goes on to enumerate his measures against immediate famine, his social and moral reforms (deliberately including his encouragement of emancipists), his insistence on religious worship and on marriage (as against 'the disgraceful and immoral state of Concubinage, which I found generally prevailing'), his works policy, his treatment of the aborigines, his orphan schools (male as well as female), and many other policies and institutions for which he had been responsible. His statistics of the colony's growth may be shown in tabular form:—

	1810	1821
Population	11,590	38,778
Cattle	12,442	102,939
Sheep	25,888	290,158
Acreage cleared and tilled ..	7,615	32,267
Customs duties levied, about ..	£8,000	£38,000

He added a list of public works occupying over 17 pages of the *Historical Records of Australia*—at Sydney, Parramatta, Newcastle, 17 other townships east of the Blue Mountains and two west, Hobart and two other townships in Tasmania, besides five turnpike roads (80 miles) and nine other carriage roads (196 miles). These are practical evidence of his good government; but it was his unbreakable confidence in the colony's future, his stimulating enthusiasm for every advance in material or moral welfare, his clear-cut determination to make New South Wales there and then a model reformatory and, in good time, free and self-supporting, that constitute his claim to rank

as the greatest and most beneficent governor Australia has seen.

See Bathurst's *Instructions to Mr. Bigge*; Bigges *Reports*, 3 vols. (London, 1822-3); and Phillips's *A Colonial Autocracy* (London, 1909).

J.Sa.

Macquarie's second wife, born Elizabeth Henriette Campbell (1778?-1835), deserves notice not only for the aid she gave her husband in all his benevolent enterprises but for her own independent influence on the development of New South Wales. This, as might be expected, was exercised chiefly in respect of charitable work, especially among the women of the settlement; thus Macquarie's reform of the female orphan institution, though officially attributed to him alone, was known to be largely of her devising, and Michael Robinson (q.v.) explicitly celebrates the 'maternal Fondness' that from that time on cherished the orphans. In the same way, while Macquarie established the school for aboriginal children at Blacktown, it was his wife who personally visited the school and taught the girls to thread needles and sing hymns. She exercised a steady supervision over the settlers' schools also, and consistently advised parents to have their children vaccinated. She was interested in architecture, had her say in the building of government house and of the church at Parramatta, and planned a road along the foreshores of Port Jackson from the mouth of the Tank Stream (q.v.) to Woolloomooloo Bay, on the western point of which she had a seat hewn in the rock to view the harbour. This seat, known ever since as 'Mrs. Macquarie's Chair' (the misnomer 'Lady Macquarie's Chair' is occasionally revived), still exists. Her Christian name was given to Elizabeth Bay, her maiden name to Campbelltown, and the name of her father's estate to the district of Airds near Appin. After Macquarie's death she lived on in London, made intermittently miserable by the profligacies of her son. She died at Jarvisfield in the island of Mull on 11 March 1835.

J.P.McG.

Macquarie Perch, a freshwater fish (*Macquaria australasica*) which is chiefly confined to the western rivers of New South Wales, though it also occurs in some eastern streams. It is a valuable food-fish, attaining a length of 15 inches, and is sometimes incorrectly called 'black bream' or 'blackfish.'

A.R.McC.

Macrozamia. See CYCADACEAE.

Madden, SIR JOHN (1844-1918), born at Cork in Ireland on 16 May 1844, and educated privately in England and France and at the university of Melbourne (B.A., 1863; LL.B., 1865; LL.D., 1869), came with his parents to Victoria in 1857. In 1868 he was admitted to the Victorian bar, and in 1871 entered politics, unsuccessfully contesting an election for West Bourke; this constituency, however, returned him to the legislative assembly at the head of the poll in 1874, and he joined McCulloch's fourth ministry (1875-7) as minister of justice. Seeking re-election after this appointment, he was rejected by West Bourke, but returned in 1876 by Sandridge (now Port Melbourne), and held that seat till the close of his political career. In 1880 he was James Service's minister of justice for five months, but did not hold office again, and in 1883 retired from politics. He refused several offers of a judgeship, but in January 1893 was made chief justice in succession to George Higinbotham (q.v.). On several occasions he administered the government of the colony in the absence of a governor (see GOVERNORS), and in 1899 was formally appointed lieutenant-governor. Outside politics and the law his main interest was in education. In 1875-9 he was warden of the senate of the university of Melbourne, in 1889-97 vice-chancellor, and from 1907 to his death chancellor. During a visit to England in 1906 he received honorary degrees from the universities of Oxford and Aberdeen. He died at Melbourne on 10 March 1918. (Kt. Bach., 1893; K.C.M.G., 1899; G.C.M.G., 1906.)

J.V.C.-B.

Mado, a small fish (*Atypichthys strigatus*) very common round wharf-piles in inlets along the coasts of the southern half of Australia. It affords endless sport to juvenile anglers, but is too small to be of value as a table fish, as it rarely attains a length of ten inches, and is usually much smaller. In colour it is yellowish, with several brown longitudinal bands. An allied species, *A. latus*, is commonly known at Lord Howe Island as 'leather-jacket,' but has no relationship to the true leather-jackets (Monacanthidae) which are so plentiful in Australian waters.

A.R.McC.

Magnesite, a mineral consisting chiefly of magnesium carbonate, occurs in all mainland States of the Commonwealth; some of the deposits are of considerable extent, and most of them of exceptional purity. Attunga near Tamworth (11,546 tons) and Fifield west of Parkes (2265 tons) were the main New South Wales sources in 1925; a little was raised near Cobar, but none in the Bingara and Braidwood areas, which had given good yields in previous years. The amount produced in New South Wales in 1925 was valued at £12,832. A few tons are raised at Heathcote in Victoria and at Beetaloo in South Australia. The deposits near Rockhampton and Bowen in Queensland, Tumby Bay and Leigh Creek in South Australia, and Bulong near Kalgoorlie in Western Australia, are not being worked. The mineral is used principally for fire-bricks and furnace-linings, and sometimes for flooring. The establishment of a flourishing magnesite industry is hampered by the lack of a market for the large amounts of carbon anhydride obtained during its treatment; as long as this by-product cannot be utilized, the mineral does not pay for working in the small quantities required by Australian industries.

Magnoliaceae, a family of trees or shrubs spread chiefly over tropical and temperate Asia and western America. Two genera with seven species are indigenous to Australia. *Drimys* has five indigenous species; *D. aromatica* (Pepper Tree) is in the humid coastal forests a large shrub or small tree, but becomes a dwarfed, prostrate shrub at the 5000-feet levels of the Australian Alps or the mountains of Tasmania. It has small greenish-yellow flowers and globular berries; the latter are a fair substitute for pepper or allspice. The leaves and bark also have a hot, biting taste. The bark closely resembles that of *Drimys Winteri* (Winter's Bark, a South American species), and is said to be sometimes used instead of it as a remedy for scurvy.

Magpie-lark or **Peewee,** a black-and-white bird (*Grallina cyanoleuca*) peculiar to Australia, anomalous in form and habits. Its true position in classification is still uncertain, though

by some authors it has been placed among the Corvidae (crows) and by others among the Prionopidae (wood-shrikes). Throughout the greater part of Australia this is one of the commonest and best-known birds, and rejoices in a variety of popular names. The name 'magpie-lark' was presumably bestowed upon it because it runs on the ground like a lark and has pied plumage; 'little magpie' or 'Murray magpie,' also on account of its coloration; 'mudlark,' owing to its preference for the muddy banks of creeks and waterholes; and 'peewee' or 'peewit,' in imitation of its frequent call. Its food consists of pond-snails and insects; in search of the latter it visits open paddocks, gardens, and cultivated land, running actively about on its comparatively long, stilt-like legs. Its flight is peculiar, some-

Magpie-lark (*length* 10½*in.*)

what laboured though straight, and accompanied by noisy flapping of the rounded wings at the outset. Its call of 'peewee, peewee' is frequently uttered when it settles, and sometimes when it is on the wing.

The sexes are similar, but may be distinguished by the fact that the throat is black in the male and white in the female. The nest is an open structure, large in proportion to the bird, placed on the horizontal limb of a large tree and composed of mud, mixed with a little grass to strengthen it, and lined with grass. The eggs are four or five in number, whitish in ground-colour, and thickly marked with purplish-brown spots, which usually unite to form a zone round the larger end. When nesting, magpie-larks are pugnacious, chasing away crows, kookaburras, and even eagles from the neighbourhood of their home by darting at them while uttering their shrill call. In a chase of this kind other birds of the same species within hail will join. They are rather sociable with their own species, and large parties often unite during autumn and winter to roost in some favourite clump of trees.

W.B.A.

Magpies, perching birds about 17 inches in length, with black-and-white plumage, belonging to the genera *Gymnorhina* and *Strepera*. The former genus contains the birds universally known as magpies in Australia, though, as they have no special connection with the magpies of England and America, ornithologists have invented for them the names 'crow-shrike' and 'piping-crow.' The latter term may be said to have official or legal sanction, since the white-backed magpie, which appears in the coat-of-arms of South Australia, is described in the language of Heralds' College as a 'Piping-crow volant, perchant.' (The remarkable feat of flying and perching at the same time has been achieved by the artist who drew the bird for the coat-of-arms, but not by the bird itself.) The birds of the other genus, *Strepera*, are variously known as bell-magpies or black magpies, as well as by the aboriginal name of 'currawong' in New South Wales and Queensland, and by the less harmonious term 'squeaker' in Western Australia.

It was usual until recently to place *Gymnorhina* among the Laniidae (shrikes); *Strepera* was classed with the Corvidae (crows). As long ago, however, as 1876 A. R. Wallace suggested that they were closely related to one another and to the genus *Cracticus*, containing the Australian butcher-birds (q.v.), and recent investigation of their anatomy by Dr. J. A. Leach of Melbourne has confirmed this suggestion. The three genera, therefore, are now united to form the family Gymnorhinidae. Both genera of magpies are peculiar to Australia and Tasmania.

Throughout northern Australia and eastern Australia north of the Murray the Black-backed Magpie (*Gymnorhina tibicen*) is the representative of its genus; in eastern Australia south of the Murray, and in South Australia and Tasmania, the White-backed Magpie (*G. hypoleuca*) takes its place. The distinction between them is implied in their names, but in the region where the two species meet intermediates are not uncommon. In south-western Australia a third species, the Varied-backed Magpie (*G. dorsalis*), is found; the adult male of this form resembles the white-backed magpie, the females and young have the back mottled with blackish-brown, like the black-backed magpie.

Magpies are among the most popular of Australian birds through their abundance, their melodious songs, and their bold habits. When nesting, they will attack eagles and hawks, and even men. They do an immense amount of good by devouring grasshoppers and other large insects, and mice; but, unfortunately, in many districts their numbers have been seriously diminished by poison laid for rabbits. Their nests

Black-backed Magpie.
(*length* 17*in.*)

are large open structures of sticks, built in trees; they lay from three to five eggs, which vary greatly in colour—most are bluish-gray in ground-colour, with clouded markings of brown.

Magpies are often kept in confinement, and in addition to their own notes learn to whistle simple tunes and sometimes to speak a few words. They are sociable birds, uniting in flocks and

feeding harmoniously in company, often indulging in mimic contests and pursuit of one another, apparently for enjoyment. At the commencement of the breeding-season, however, the males become pugnacious and fight savagely.

The bell-magpies (*Strepera*) are shyer and less sociable birds than their relatives, and their loud calls, though fairly melodious, cannot be regarded as musical. They build large nests of sticks in trees, and lay three or four eggs, which are brownish with darker markings. Their food consists of insects and fruit, mostly obtained on the ground. The Pied Bell-magpie (*S. graculina*) of eastern Australia—oftener called 'scrub-magpie' or 'currawong'—is perhaps the best-known. The Hill Bell-magpie (*S. arguta*) is confined to Tasmania; the Black-winged Bell-magpie (*S. melanoptera*) occurs in Victoria and South Australia; the Black Bell-magpie (*S. fuliginosa*), often called the 'black jay,' is found in Tasmania (where it is known simply as the 'black magpie') and south-eastern Australia; the Gray Bell-magpie (*S. versicolor*) ranges from south-eastern Australia to the south-west, where it is called the 'squeaker.'

Other birds sometimes known locally as magpies are the chough, q.v., (occasionally called 'black magpie'), the magpie-lark (q.v.), called also 'little magpie' and 'Murray magpie,' and the white-shouldered caterpillar-eater or 'midget magpie,' a member of the family of cuckoo-shrikes (q.v.). W.B.A.

Mahony, Francis (1862-1917), son of an Irish father and a Cornish mother, and kinsman of the famous 'Father Prout'—Father Francis Sylvester Mahony—was born in Flinders-lane, Melbourne, on 4 December 1862 and brought to Sydney when he was ten years old. On leaving school he entered an architect's office, but much preferred attending Anivitti's classes at the old Academy of Art (see Art Galleries), and soon began to paint for a livelihood. Most of his black-and-white work was done for the *Picturesque Atlas of Australasia* and the *Bulletin*, or to illustrate volumes of Australian verse and prose; the Art Gallery in Sydney has three oil-paintings by him. While his special excellence lay in his treatment of horses—and he knew them 'inside out'—he dealt also with other phases of bush-life, and with Charles Conder and Henry Fullwood pioneered for artists the since much-bepainted Hawkesbury valley. For a time he was instructor to the Art Society of New South Wales; failing, however—mainly for personal reasons—to make his art provide a living in Sydney, he migrated to London in or about 1904. There he was occasionally seen at the Chelsea Arts Club, and oftener at the Langham Sketching Club, but lived for the most part as a recluse, and died in 1917. He was buried in Hanwell cemetery; a headstone, erected by old Sydney friends, marks his grave.

He was generally known as F. P. (Francis Prout) Mahony; but the 'Prout' was an addition of his own.

Maiden, Joseph Henry (1859-1925), born at St. John's Wood, London, on 25 April 1859 and educated at the City of London School, was prevented from entering Cambridge by ill-health that necessitated a voyage to Australia, and in 1881 was appointed curator of the New South Wales technological museum. In 1894 he became also superintendent of technical education, and established a system of instruction in wool-classing which has proved of great value. In 1896 he was made government botanist and director of the Sydney botanic gardens (q.v.), an appointment which involved the superintendence of the Domain, Centennial Park near Randwick, and the state nursery at Campbelltown. He largely remodelled the gardens, and established a national herbarium, to which through his agency were presented nearly 600 botanical specimens collected by Banks and Solander in 1770. In 1912-22 he was lecturer in forestry and agricultural botany at the university of Sydney. In 1900 he attended the international botanical congress held at Paris, and subsequently investigated European methods of forestry and horticulture; in 1904 he was invited to attend the Cambridge meeting of the British Association for the Advancement of Science. He was secretary of the Australasian Association for the Advancement of Science in 1907-21, and received in 1923 the Association's Mueller medal and in 1924 the Clarke memorial medal from the Royal Society of New South Wales. Among other honours bestowed on him may be mentioned the gold medal of the Linnean Society of London (1915), a fellowship of the Royal Society (1916), and the grand medal of the Acclimatization Society of France. In 1924 he resigned his appointments and lived in retirement, busying himself with botanical researches. He died at Turramurra near Sydney on 15 November 1925.

Among his published works are: *Useful Native Plants of Australia* (1889), *Flowering Plants and Ferns of New South Wales* (1895, in collaboration with W. C. Campbell), *Manual of the Grasses of New South Wales* (1898), *Forest Flora of New South Wales* (issued in parts between 1902 and 1925), *A Critical Revision of the Genus 'Eucalyptus'* (issued in 64 parts since 1910), *The Weeds of New South Wales*, and *Life of Sir Joseph Banks* (1909). His numerous contributions to periodical literature (especially to the *Agricultural Gazette of New South Wales* and the *Journals* of the Royal and Linnean societies of New South Wales) include short memoirs of Australian botanists, and papers on prickly pear, Australian fodder-plants, plants reputed poisonous to stock, wattles and wattle-barks. He was one of the founders, and for ten years president, of the Wattle League (see Wattle Day); twice president, and for 22 years honorary secretary, of the Royal Society of New South Wales; president, and for 37 years a councillor, of the Linnean Society of New South Wales; vice-president of the Australian Research Council; and, because of his interest in the acclimatization of Australian plants in California, a vice-president of the Forestry Society of California. (I.S.O., 1916.)

Maize. In the early days of New South Wales maize was more extensively grown than any other crop; in 1791 the area under maize at Parramatta was 300 acres, of wheat only 44—in 1792 1186 acres were under maize, and 208 under wheat. The maize-yield was allegedly 50 bushels per acre. Maize was also the principal crop at Norfolk Island, where it proved itself 'constant, certain, and plentiful;' as a rule two crops were harvested annually, averaging 45 bushels each. The yield often rose to 70-80 bushels, which amount was also obtained in the

alluvial river-flats of New South Wales. For the coastal districts it was a much more reliable crop than wheat. Even 40 or 50 years ago the area under maize was almost the same as that under wheat, but in recent years the coastal districts of New South Wales have found dairying more profitable.

Maize can be grown nearly everywhere on the mainland of Australia, but the highest yields are obtained in the eastern coastal districts. A large proportion is grown for green fodder and ensilage. It is excellent for sowing immediately after land has been cleared of timber, especially when the soil is rank or sour. When new land is cleared for dairying, it is a common practice to sow maize as a first crop, even before the timber is burnt off.

Almost the whole of the Queensland crop is grown in the Moreton (40 per cent), Darling Downs (28 per cent), and Wide Bay (22 per cent) districts. In 1909 the State department of agriculture acclimatized a large number of varieties from America. Both in New South Wales and in Queensland the government supplies seed to farmers, purchases, classifies, and grades their produce, and distributes fresh seed for the next season. In Victoria the area, though smaller than that in New South Wales, is much more productive. Good results are recorded from the sandy soils along the coast, which are not naturally fertile; whereas the acre-yield for the 11 years 1863-74 was only 15 bushels average, it has been steadily increased to the present high level (25½) by the use of good methods of cultivation.

The following are the figures for 1924-5:—

State.	Area under crop.	Yield.	Value.
	acres	bushels	£
New South Wales .	146,564	4,208,200	824,106
Victoria	23,126	891,987	189,547
Queensland	229,160	7,330,827	1,435,619
South Australia ..	7	276	87
Western Australia .	71	333	113
Federal Territory .	21	420	80
Commonwealth ...	398,949	12,432,037	2,449,552

The average acre-yield for the Commonwealth for the ten years 1914-24 was 24.59 bushels, which is 4.73 bushels less than that of the United States, the principal maize-producing country in 1923, but is satisfactory when compared with that of other countries. A small but fluctuating trade in the export and import of maize depends on the success or failure of the local crop. In 1915-16, a year of drought, nearly 4½ million bushels were imported; in 1923-4 the excess of imports over exports was 2,534,891 bushels. The 1924-5 year, however, was exceptional in that the surplus of exports over imports was 2,553,572 bushels.

The export-trade in cornflour is at present very small—in 1924-5 it was 19,177 lb. valued at £490. A moderate amount is annually imported, the principal sources being the United States and Great Britain; in 1924-5 the import was 299,198 lb. valued at £5273.

The principal varieties of maize grown in Australia are:—*Extremely early*: Sundown; *Very early*: Early Morn, Golden Glow; *Early*: Wellingrove, Gold Coin, Golden Superb, Kennedy, Golden Surprise, Iowa Silvermine, Funk's Yellow Dent, Iowa Goldmine, New England Whitetip, Auburn Vale, Craig Mitchell; *Mid-season*: Hickory King, Boone County White, Leaming, Coodra Vale, Golden Nugget, Early Clarence, Golden Beauty, Narrow Red Hogan; *Late*: Yellow Hogan, Fitzroy, Large Red Hogan, Yellow Moruya, Ulmarra Whitecap.

Factories for the manufacture of maize-products have been established in most States. From the endosperm are obtained cornflour and starches, of which some are used in laundries, some in the preparation of baking-powders and in the treatment of paper and cotton. From maize-starch is also obtained maize-syrup (glucose) which is used in technical processes connected with confectionery, jams and jellies, and fruit-preserving, as well as by tanners and brewers. Power-alcohol, dextrin, and gluten-meal are also obtained from maize, and the germ removed in the preparation of starch yields a valuable oil, which is used for soap- and paint-making, lubricating, and lighting, and can be converted into rubber-substitute. The mass from which the oil is expressed makes nutritious stock-food.

Mallotus, a genus of Euphorbiaceae, widespread over tropical Asia and Africa; 10 species are indigenous to Australia, extending from New South Wales through Queensland to northern Australia. The male and female flowers are on distinct plants; fruit a red or yellow capsule, separating into two celled carpels. From the glandular hairs that coat the fruits of *M. philippinensis* is made a red powder, called by the Hindus 'kamala' and used by them as a vermifuge. Silk-dyers boil it with carbonate of soda to make a red dye of great beauty; the bark also is used for dyeing. The tree has a hard, tough timber, gray to light red in colour, which is liable to warp and shrink in drying. The capsules of *M. discolor* yield a yellow dye. This species has a soft, easily worked timber.

Malvaceae, a large and widely dispersed family consisting of herbs, shrubs, or soft-wooded trees with toothed, lobed, or variously divided leaves. Fifteen genera and 125 species are indigenous to Australia. The fruits are usually capsular, rarely a berry. The genus *Malvastrum* (herbs or undershrubs with red or yellow flowers) is chiefly American, with a few species in South Africa; two species are indigenous to Australia, of which *M. spicatum* is regarded by many squatters as a valuable fodder for sheep. The large genus *Abutilon* is well distributed over warm regions; 26 indigenous species—shrubs or herbs, usually with heart-shaped leaves—range across the continent. The flowers are yellow or white; fruit-carpels angular and pointed. The bark of *A. oxycarpum* yields a useful fibre. *A. indicum* possesses demulcent properties. Several species are in common cultivation as ornamental garden plants. The genus *Pavonia* is chiefly South American; the only indigenous species, *P. hastata* (also found in South America), extends from New South Wales to Queensland and is frequently grown as an ornamental shrub. The plants produce two kinds of flowers, one perfect, the other with the corolla suppressed and not opening (cleistogamous); both forms produce fertile seeds. The flowers shade from blue to purple, being darker at the base. The genus *Urena* is largely tropi-

cal, the only indigenous species, *U. lobata*, having a wide, warm-country range from Queensland into northern Australia. It is a tall herb, with pretty pink flowers, which are used in Brazil as an expectorant. The inner bark yields a fibre resembling jute. The genus *Lagunaria* contains one species, *L. Patersoni*, which extends to Norfolk Island. It is a coastal tree in northern New South Wales and Queensland,

Pavonia hastata.

and is frequently planted for shade and shelter in exposed positions on the sea-coast. The genus *Gossypium* (which includes the various exotic species or varieties that produce commercial cotton) is represented by *G. Sturti*, a shrub several feet in height, more or less marked with black dots. It is an inland species, ranging from South Australia to Queensland, and affords food for stock in dry country. See ADANSONIA, BOMBAX, HIBISCUS, LAVATERA, PLAGIANTHUS, SIDA, THESPESIA.

Mammals. The class Mammalia includes all those vertebrate animals in which the young are nourished for a time after birth by the milk of the female parent. The following orders of mammals comprise existing representatives:—

(1) Monotremata (monotremes).
(2) Marsupialia (marsupials).
(3) Edentata—sloths, armadillos, African and American anteaters.
(4) Cetacea—whales and porpoises.
(5) Sirenia—dugongs and manatees.
(6) Ungulata (hoofed mammals), comprising horses, rhinoceroses, tapirs, pigs and hippopotami, cattle, sheep, goats, deer and camels. With these are grouped elephants and hyraces, which, though not hoofed in the strict sense, are more nearly related to this than to any of the other orders.
(7) Carnivora, including cats, hyaenas, dogs, bears, weasels and otters, together with seals and walruses.
(8) Rodentia (rodents), comprising rats and mice, hares and rabbits, squirrels, jerboas, beavers and porcupines.
(9) Insectivora (insect-eating mammals), including moles, shrews and hedgehogs.
(10) Chiroptera (flying mammals)—bats, and 'flying foxes' or fruit-bats.
(11) Primates, including lemurs, apes and monkeys, and the human race.

The most important points to be noted in regard to the mammalian fauna indigenous to Australia are:—(*a*) the occurrence in this region alone of the only two surviving families of Monotremata; (*b*) the predominance of numerous and varied representatives of the order Marsupialia, which, at the present day, is almost entirely restricted to this region, though it was previously widely distributed; (*c*) the absence of representatives of most of the other orders.

See the various mammals under their own names, and consult Gould's *Mammals of Australia*; Lydekker's *Royal Natural History*, vol. iii; Beddard's 'Mammals' in the *Cambridge Natural History* (1902); Ogilby's *Catalogue of Australian Mammals* (1892); Lucas and Le Souef's *The Animals of Australia* (1909); Wood Jones's *The Mammals of South Australia* (1923-5).

W.A.H.

Mandated Territory OF NEW GUINEA, THE, comprises the north-eastern section of the island of New Guinea (under German rule known as Kaiser-Wilhelms-Land) and the islands adjacent to it, together with the Bismarck Archipelago and the two north-western Solomons. The area of the Territory is approximately 91,000 square miles, of which the mainland of New Guinea accounts for 70,000. On the north the Territory is bounded by a conventional line running along the equator from the 141st to the 160th meridian of east longitude; the western boundary-line runs due south along the 141st meridian to its intersection with 5° S. lat., and separates the Territory from Dutch New Guinea; the southern coincides with the northern boundary of Papua on the mainland, and runs thence along 8° S. lat. to the 154th meridian, and thence roughly north-eastward to the intersection of 4° 35′ S. lat. with 160° E. long.; the eastern boundary runs along the 160th meridian.

Discovery and Exploration.—For discoveries on the New Guinea coast before 1615 see AUSTRALIA, DISCOVERY OF. In 1615 the Dutch navigators Le Maire and Schouten made the first important surveys along the north-eastern coast of the island. In 1700 William Dampier (q.v.) visited and named New Britain and other islands off the north-eastern coast. In 1767 Carteret, and in 1768 Bougainville, surveyed part of the northern Solomons; in 1769 d'Iberville visited the islands off the north-eastern coast, and in 1788 John Shortland (q.v.), on his way back to England from Port Jackson, discovered the group that bears his name. Other visitors were Hunter in 1791, d'Entrecasteaux in 1792, and von Krusenstern in 1803-4. In 1827 Dumont d'Urville, and in 1838 McCluer, sailed along the north-eastern coast; Belcher in 1840 also visited these parts. John Moresby in H.M.S. *Basilisk* made surveys in 1874. In 1875-7 the *Challenger* expedition visited these

MAP OF MANDATED TERRITORY OF NEW GUINEA

waters, and Baron von Schleinitz (one of the few German visitors of the early days) explored the coast-line from Fortification Point to the mouth of the Sepik, as well as the Purdy Islands and parts of the Bismarck Archipelago. Between 1875 and 1885 four English naval officers—Lieutenants Bower, Richards, Oldham, and Field—surveyed the north-eastern coast, and in 1884 Finsch was engaged in similar work. Next year Germany annexed the Territory, and in 1895 the German survey ship *Moewe* began the survey and astronomical determination of many points along the coast of Kaiser-Wilhelms-Land and in the Bismarck Archipelago; in 1906 the *Planet* continued this work, surveying and charting the more important harbours, the traffic routes between New Guinea and New Britain, and the channels between the principal islands.

Up to this time the Germans had done little exploration work away from the coast of the mainland or the larger islands—it was not until 1913 that a serious attempt was made to examine the unknown interior. In 1886 the *Samoa* and in 1907 the *Siar* surveyed the lower part of the Markham River. In 1896 the Ramu River was entered by the *Ottilie*, and in 1898 by the *Johann Albrecht* and the *Herzogin Elizabeth*. In 1903 this river was ascended some distance by the *Stephen*. In 1909 the Hamburg South Seas expedition explored a small inland district of New Britain. In 1885 Dr. Finsch investigated the Sepik River (which was renamed the Kaiserin Augusta); in 1909 the Hamburg South Seas expedition explored it for 200 miles; in July 1910 the Dutch-German Boundary Commission traversed an area near the boundary from the northern coast to the Sepik. During this expedition Dr. Schultze discovered one of the river's main sources in the Peripatus Mountains near the Anglo-Dutch boundary. In 1913 the Stolle expedition again explored the Sepik valley and mapped out many tributaries. In July 1914 Commander Cumberlege of the Australian navy took destroyers 200 miles up the river and proceeded in the *Nusa* 150 miles farther. Since the Australian occupation New Britain has been crossed from Gasmata to Stettin Bay, and the Ramu River explored for 170 miles by an expedition under the leadership of Evan Stanley. There still remains a vast area of *terra incognita*, but exploration is progressing steadily; as in Papua, the dense, humid forests with their tangled mass of lianas and undergrowth, and the high, inaccessible mountain ranges, form a great barrier to journeys inland.

Physical Features.—At present the most important part of the Mandated Territory consists of numerous islands, the chief being the Bismarck Archipelago and the northern Solomons—together more than a quarter of the total area. The Bismarck Archipelago comprises more than 600 islands, the largest of which is New Britain (9266 square miles); New Ireland contains over 5000 square miles and New Hanover 579 square miles. Included in the Archipelago are the Admiralty group, consisting of Manus, Lou, Mbuke, Rambutyo, Baluan, Purdy (Nager) and several smaller islands; the Hermit and Ninigo groups and Kaniet, Sae, and Wuvulu islands lying north-west of the Admiraltys; and the St. Matthias group north of New Hanover. The northern Solomons include Bougainville (3500 square miles), Buka close to and north of it, and the Nukumanu, Tauu, Kilinailu, Nuguria, and Nissan groups, east and north-east of New Ireland. Adjacent to the mainland are Bagabag, Karkar, Manam, Long, Crown, Tami, Tarawai, Valif, Kairiru, Mushu, and the Schouten islands—these are not part of the Bismarck Archipelago. The island territory is for the most part volcanic and mountainous. Some of the islands, though but a few miles wide, rise to several thousand feet above sea-level, with a narrow coastal fringe of low or flat land. A few, however, are of comparatively recent origin, coral islands or atolls; others are of coral rock lifted well above sea-level. Most of the coral islands lie north-west of the Bismarck Archipelago and north and north-east of Buka and Bougainville; a few are near the coast of New Guinea, and among the smaller islands of the Admiralty group.

The concavo-convex island of New Britain has a very irregular coast-line and several good harbours—the most important being Blanche Bay with its inlier Simpson harbour, in the northern peninsula, and Talasea harbour on the main north coast. In the Witu group, north-west of New Britain, are two landlocked anchorages, Johann Albrecht and Peter harbours. At the north-western end of New Ireland is the fine harbour of Kavieng. On Bougainville good anchorages can be found at Kieta on the east, Tonolei on the south, and Gazelle harbour on the west; Buka has but one, Queen Carola harbour. Along the New Guinea coast good harbours are most numerous between Cape King William and the southern border, the more important being Morobe (Adolf harbour), Wurtemberg and Baden bays, the northern part of Sachsen Bay, Nassau Bay, Preussen Road, and Hanisch and Finsch harbours. The Maclay coast (see MIKLUHO-MAKLAY), which extends from Cape King William to the eastern end of Astrolabe Bay, has many more or less shallow bays separated by projecting headlands. North of Astrolabe Bay are Madang (Friedrich Wilhelmshafen) and Sek (Alexishafen) harbours. Aitape roads and Vanimo harbour lie towards the north-western end of the Territory.

There are swampy lowlands in the lower reaches of the larger rivers and occasionally for a few miles inland from the coast-line. Otherwise north-eastern New Guinea is extremely mountainous, as are most of the islands off it. Almost the whole Territory is covered with dense forests, grassy lowlands being rare. Close to the Papuan border in the south-west the Star Range forms the watershed between the Sepik River and the Fly River (in Papua). Its highest peak is Capella (13,000 feet). North-east of these mountains begins the main central range, which runs east and south-east through the Territory. In the west it is called the Victor Emanuel Range (10,000 to 12,000 feet), then the Central Range as far as Mount Hagen (11,500 feet), where it unites with the Schrader (7700 feet) and Bismarck ranges: in the latter are Mounts Herbert and Wilhelm, both over 13,000 feet. Near the source of the Ramu and Markham rivers the main range is known as the Kratke Mountains (Mount Zoller, 10,000 feet); near the Papuan border we know little about it, but its highest peak in this district is Mount Chapman (11,876 feet). Between the upper Ramu and the Maclay coast, opposite Vitiaz Strait, lies the Finisterre Range (Mounts Disraeli and Gladstone, 11,000 feet); this range continues into the Huon peninsula, where it is known as the Rawlinson and Saruwaged ranges —in the latter a peak of the same name is over 13,000 feet in height. Coastal ranges in the north-west run from the Dutch border to

Wewak opposite Musau Island; they are the Bougainville Range (4000 feet), the Torricelli Mountains (3000 feet), and the Prince Alexander Range (4000 feet). Between the Bougainville Range and the upper Sepik lie the Bewani Mountains (4000 feet). South of the Victor Emanuel Range, running into Papua, is the Müller Range, the highest peak of which is Mount Blücher. On the islands the highest is Mount Balbi (10,171 feet) on Bougainville. The whole of New Ireland is mountainous; the Schleinitz Range rises steeply to 4000 feet and includes an extensive limestone plateau 2600 feet above sea-level, called Lalet; on the north-eastern coast fertile plains lie between the sea and the mountains, but along the southern coast the Hahl and Verron ranges rise 6000 feet directly from the shore, and in the centre is the Hans Meyer Range. In New Hanover the Tirpitz Range rises 2870 feet, and on Manus there is a mountain of about the same height.

The mainland of New Guinea contains comparatively few evidences of volcanic action, but a curved line of crater islands (many active) stretches along the coast from the Schouten group to New Britain. The islands off the north-eastern coast of New Ireland are probably peaks of a submerged mountain-chain. In New Britain Ulawun (the Father, 7546 feet) and Bamus (the South Son, 7376 feet) are active volcanoes near Open Bay; on the Willaumez peninsula are several volcanoes of varying heights, and numerous geysers. In the extreme west is another group, of which Mount Talawe is said to be active. On the Gazelle peninsula near Blanche Bay there is a group of volcanic peaks, of which Tavurvur is still active at long intervals; the Mother (Kombiu, 2250 feet), the North Daughter (Towanumbatir, 1770 feet), and the South Daughter (Turanguna, 1750 feet), make up a conspicuous feature of Rabaul scenery. Lihir Island off New Ireland has active mud-craters. On Bougainville the central mountain-mass has crater-like formations, and Mount Bagana (6500 feet) is an active volcano. On Buka the southern ridges are of volcanic formation. Bam, Manam, and Karkar, which lie off the New Guinea coast between the Sepik and Madang, have on them active volcanoes.

On the larger islands there are few navigable rivers, and on the mainland only three of importance, the Sepik, the Ramu, and the Markham. The Sepik, which rises in the Star and the Victor Emanuel ranges, has a serpentine course of over 600 miles, flowing at first northward and then practically east for several hundred miles until it enters the sea near Cape Girgir. At its mouth it is about 2000 yards wide, and the shallowest part of the channel is 5 fathoms; it is navigable for large ocean-going steamers for 60 miles, and for smaller vessels (drawing up to 10 or 12 feet) for 300 miles. In the lower and middle reaches it flows through a broad plain, mostly of sago-swamps. Innumerable tributaries drain the ranges on either side, but many are soon lost in extensive flood-areas. The Ramu, which flows into Broken Water Bay, drains the central portion of the Bismarck Range on the west and the south-western part of the Finisterre Range on the east. Its mouth, 430 yards wide, is closed by a bar; but there is an entrance channel about 2¼ fathoms deep. It is approximately 400 miles in length. Between the sources of the Ramu and the Markham is a divide a few miles wide and only 1350 feet above sea-level. The Markham drains the southern portion of the Finisterre Range, the Herzog Range to the south, and the Albert Range near the Papuan boundary. Of minor importance are the Tami, near the Dutch border; the Golgol and the Kabenau, which flow into Astrolabe Bay; the Bulong, draining the Kai peninsula and flowing into Huon Gulf; and the Bu, entering the sea near Cape Rawlins. Close to and sometimes crossing the Papuan boundary is the Waria, which flows into Hercules Bay, and drains a large area of auriferous country.

Geology.—Until further geological field-work has been accomplished, it is impossible to map the exact localities where metamorphic rocks occur, but probably the greater part of the main central chain of mountains and many of its subordinate ranges make up together one great pre-Cambrian complex, which may also include the southern portion of the Bewani Mountains, the Adelbert Range, the Finisterre, Saruwaged, and Rawlinson ranges, and the Huon peninsula. Part of the Baining area in the Gazelle peninsula of New Britain is undoubtedly of this series, and gneisses have been reported in the Schleinitz and Rossel ranges of New Ireland and in the mountainous district of Bougainville south-west of Kieta. Archaean and plutonic rocks have been found throughout this series. Where these rocks occur in the head-waters of the Waria and its tributaries payable gold has been obtained; the area including the upper waters of the Ramu and Markham is somewhat similar, but has not been proved to contain gold in payable quantities. Pre-Cambrian and archaean schists are represented in the Hunstein Mountains on the middle Sepik, and are well developed (with diorites and diorite porphyrites) in the ranges south of the Sepik and east of the 142nd meridian. Serpentinized peridotite, associated with plagioclase basalts which intrude late Tertiary limestone, has been discovered in the north-western corner of the Bougainville Range. Plutonic and hypabyssal intrusions occur in the Bewani and Finisterre ranges. In New Hanover and New Ireland older igneous rocks have been noted, but very little is known about them. Throughout the volcanic zone the younger effusive series of rocks is predominant. On the October River (a tributary of the Sepik near the 141st meridian) outcrops of Mesozoic rocks were found, and on examination were reported to contain fossils like those of Jurassic strata in the Moluccas. In the Bougainville Range and the Torricelli Mountains Cretaceous beds have been recorded, and alveolina limestone in the Finisterre Range near Mount Disraeli; the limestone massif in the Saruwaged Range is also probably alveolina. The Papuan government expedition of 1924 found *Lepidocyclina* limestone on the southern slopes of ranges drained by the Fly and Palmer rivers, so that earlier (possibly Mesozoic) rocks may occur on the northern slopes of the divide in the Mandated Territory. Of the early Tertiary series, oligocene and eocene limestones and glauconitic sandstones have been recorded from the south-eastern and western slopes of the Verron Range in New Ireland, and from the northern slopes of the Bewani Mountains on the mainland. There is still much field-work to be done before this series can be fully located. Of the late Tertiary series more is known.

According to Evan Stanley late Tertiary limestone is well developed on most of the islands. On the mainland the series is mostly restricted to the littoral in the north-east, but east of

Aitape extends into the mountains. On the 141st meridian, south-east of Germania Point, lies an extensive limestone plateau 600 feet above sea-level; and it is probable that all the coastal sandstone ranges in the north-west are capped with coral limestone. In the Bewani Mountains brine-springs—usually associated with occurrences of petroleum (see OIL)—have been recorded; it is probable that Plio-Miocene oil-bearing strata stretch along the coast-line from the Dutch boundary to Astrolabe Bay, being more in evidence in the Vanimo, Aitape, and Madang hinterlands and up the Sepik valley. In the Gazelle peninsula of New Britain a Plio-Miocene series like the oil series of Papua is found in the Toriu valley, but volcanic activity in the neighbourhood may have prevented the deposition of oil in payable quantities.

Minerals and Mining.—Gold, osmiridium, platinum, tin, copper, sulphur, magnetite, manganese, and lead have been discovered, but only gold has been exploited. Phosphatic rock is obtainable in payable quantities in the Purdy Islands; west of Cape Croiselles, on Dylup plantation, the rock may contain a sufficient percentage of phosphates to make it payable, but more careful examination is required. Brown coal has been found, but may not be commercially utilizable. Clays in large quantities (some of high quality) are obtainable in various parts of the Territory, but have not been worked. Reference to the oil series has already been made; several companies are prospecting and arranging for the development of the fields, but up to the end of 1925 oil in payable commercial quantities had not been discovered.

Under the mining ordinance of 1922 a gold-field has been proclaimed in the Morobe district, and four mineral-oil and coalfields in the Aitape, Madang, Namatanai, and Kieta districts. Thirty-five miners' rights have been issued, and 36 dredging and sluicing leases. Since January 1924, when the Territory was thrown open for private enterprise, 26 mineral-oil and coal licences have been issued to prospecting companies. For the year ending 30 June 1925, 7417 oz. of gold, valued at £18,512, were exported.

Meteorology.—Like Papua, the Mandated Territory has two seasons, the north-west monsoon, from December to April—this is usually the wet season, and winds fluctuate from NW. to NE.—and the south-east trade, from May to November, which is generally accompanied by a small rainfall. Along the mainland littoral the average temperature varies from 78° to 82° Fahr.; this is low, considering its proximity to the equator, and is probably caused (*a*) by the cool north-westerly current which strikes the coasts during the south-east season, (*b*) by the numerous high mountain ranges, which cool both the north-west and the south-west winds. Hurricanes do not occur, and storms are not so violent as those prevailing farther south. On the whole the climate may be called equable, though on some islands the humidity is great and the climate enervating. Malaria is common throughout the Territory, but good health may be maintained by the judicious use of quinine, regularity in other habits, bodily exercises, and a very temperate use of alcohol. Of course even these precautions will be of no avail unless mosquito-breeding areas are reduced to a minimum.

Fauna.—Like Australia, the Mandated Territory has a great variety of marsupials and a scarcity of mammals. Of marsupials there are over 40 species, among which are two kangaroos (*Macropus papuanus* and *Thylogale jukesi*); three varieties of dorcas kangaroo (*Dorcopsis*) on the mainland, and one in the Bismarck Archipelago; and several species of tree-kangaroo (*Dendrolagus*). The Phalangeridae include one cuscus (*Cuscus masculatus*), a small squirrel-like flying opossum (*Petaurus papuanus*) found in the Solomons, two striped opossums (*Dactylopsila*) noted on the mainland, and several ring-tailed opossums (*Pseudochirus*) which occur throughout the Territory. One bandicoot (*Perameles cockerelli*) has been discovered in the Bismarck Archipelago; others are said to exist on the mainland. In the larger islands off the coast the pouched rat (*Phascogale*) occurs, as well as a native porcupine (*Zaglossus*). Among mammalia, several flying foxes (*Pteropus*) occur on the mainland, and a smaller one (*Syconycteris australis*) in the Solomons and in New Ireland. The numerous rodents include *Uromys, Chiruromys, Pogonomys,* the giant rats (*Mallomys rothschildi*), and one or two species of water-rat (*Hydromys*). Pigs and dogs are widely distributed, but not indigenous. Cattle and sheep, too, have been introduced and bred successfully. Off parts of the coast the dugong (*Halicore australis*) is found. Fishes, both freshwater and marine, abound, and the Samoan 'palolo worm' is used as food by the natives of the Bismarck Archipelago.

Reptiles are represented by a crocodile (*Crocodilus perosus*), the hawk's-bill turtle (*Chelone imbricata*) which approaches the coast from July to December, a river turtle, and a land tortoise. Monitors (Varanidae) are widely distributed, and there are several families of smaller lizards, including the skink. Frogs and toads are numerous. Over 20 species of snakes have been recorded, among them the python of the Bismarcks, where also is to be found a very poisonous snake, *Pseudelaps mulleri.* Four varieties of venomous water-snake are found; one in particular (*Platurus colubrinus*) is notable as being found among holes in the coral and on trees washed ashore.

Bêche-de-mer (*Holothuria*) is plentiful in several parts of the Territory, and pearl and trocas shell are also obtainable in commercial quantities.

Of the 178 species of birds known at present in the Territory 74 are also found in Europe, among them finches, woodpeckers, vultures, hawks, falcons, owls, hornbills, parrots, and cockatoos. Among the parrots the most noteworthy are *Eclectus pectoralis,* a *Nasiterna,* and a *Loriculus,* and among the cockatoos the brilliantly-coloured *Plissolophus ophthalmicus.* Only 12 of the 18 varieties of pigeons are represented in the islands—the most remarkable is the crested goura. Birds of paradise are distributed throughout the Territory in great variety. Of eight species of mainland cuckoos only one is found in the archipelago. The cassowary is represented by one species (*Casuarius bennetti*) and the scrub fowl by one (*Megapodius eremita*). Wild ducks and geese have also been noted. The few land mollusca which have been distinguished seem to show a relationship with those of the Indo-Malayan regions.

Flora.—The indigenous flora of the Territory seems to be largely blended with Indo-Malayan, Polynesian, and Australian types, but of the 753 species of plants found in New Guinea and the islands over 200 are endemic. In the

Solomons a species of the Zingiberaceae and one of the Sapotaceae are peculiar to the district. Among the numerous indigenous economic plants may be noted *Indigofera tinctoria*, which grows in parts of the Bismarck Archipelago; the areca palm, which supplies the natives with betel-nuts; three varieties of bread-fruit (*Artocarpus integrifolia, A. incisa* and *A. polyphema*); numerous varieties of the banana; and yam (*Dioscorea*), taro (*Colocasia esculenta*), and sweet potato (*Ipomoea batatas*) form the staple diet of the natives in addition to the fruitful coconut and the introduced cassava (*Manihot jotropha*). The sago (*Metroxylon rumphii*) is widely distributed, especially in the vast swamps of the middle Sepik. Another variety (*M. oxytracteatum*) has been distinguished near Finsch harbour. On Buka and Bougainville the natives utilize one of the Cycadaceae, from which they obtain their starchy food. In the mainland ranges a species of *Pandanus* is cultivated and supplies a food-product from its fruit. Many trees produce edible nuts in the dense forests, where wild nutmegs and ginger also grow. The sugar-cane is cultivated. Rattans and bamboos are widely distributed, and in New Britain a fibre (*Pueraria novoguineensis*) is used in the manufacture of native fish-nets. In the archipelago the pounded nuts of *Parinarium laurinum* are utilized in making a cement for caulking boats, and as a plastic mass for covering ceremonial masks. The ivory-nut palm (*Coelococcus salomonensis*) grows well in the Solomons. Tobacco is probably an introduced plant; though widely distributed, it does not seem to grow with an excellent flavour in the islands, but on the lower Sepik and Ramu, where it is prolific, better samples have been obtained. In 1882 Parkinson introduced into New Britain maize, water-melons, pumpkins and pineapples, and all have thrived excellently. Other economic plants of importance are: the nipa palm (*Nipa fructicans*) found along the tidal reaches of rivers; several varieties of mangrove (*Rhizophora*); and many timber-trees, among them cedars, acacias, eucalypts, ebony, sandalwood, *Calophyllum* (which grows only on the coast), and the shade-trees *Terminalia catappa* and *T. okari*. The latter species is confined to the mainland; the kernels of its large nuts, which have an almond flavour, are of great food-value. Two sawmills are operating in New Britain and one at Sek harbour near Madang. Most of the timber cut is used locally. As a forestry expert has not yet surveyed this territory, it is impossible at present to forecast the future of the timber industry, but the minor forest products—medicinal plants, rattans, and fibres, and perhaps gums—could be developed commercially.

Agriculture.—At the Rabaul botanical gardens experimental planting is carried out, and from it economic plants, cuttings, and seeds are distributed. Here also the special variety of eucalypt seedlings are raised for eventually planting in the vicinity of quarantine and other stations on account of the tree's salubrious exhalations. Sudan and other grasses have been grown successfully in experimental plots. Cocoa, coffee, rubber, arrowroot, kapok, and sisal hemp can also be cultivated to advantage, but at present there is little exportation of these except cocoa, grown principally at Vitu, but there are also small plantations at Madang and in New Ireland. There is no doubt that the Territory could produce far more cocoa and find a market for it in the Commonwealth, and this should not be lost sight of in dealing with the native plantations. During the last few years the exports of cocoa-beans, rubber, sisal hemp, and minor agricultural products have steadily decreased.

Copra on the other hand shows a substantial increase, but this has come about more or less automatically as fresh areas have come into bearing. There are between 350 and 400 coconut plantations in the Territory, on which 176,605 acres have been planted up, including 80,000 acres now in bearing. Of native-grown copra 6000 tons are produced annually. Swamp-rice has been experimented with successfully at Sek, and there seems no reason why the natives should not be instructed in the cultivation of this variety, as well as in the cultivation of upland rice which grows so well in Papua. Vanilla, nutmeg, lemon-grass, and maize also grow successfully. The agricultural exports for the year ended 30 June 1925, with their value in pounds sterling, were:—

	Tons	Value
Copra	39,151	815,938
Cocoa beans	135	6,949
Ivory nuts	27	312

Land and Land Tenure.—Before the Australian occupation in 1914 the German government had sold or leased to colonists and companies a total of 702,220 acres; the New Guinea Company held 369,880 acres, other companies 73,700 acres, missions 80,700 acres, and individual planters 177,940 acres. In 1922, civil government having been restored, a land ordinance similar to that current in Papua prohibited Europeans from purchasing land from a native. The administrator alone has the right to purchase, and may lease purchased land for a period up to 99 years. In agricultural leases of more than 30 years' currency the rental is 5 per cent per annum on the unimproved value—the rental for the first 10 years may be remitted. When the lease is for 30 years or less, the rental during the whole term is 5 per cent on the unimproved value, appraised every 10 years. The maximum land-area which can be held under one agricultural lease is 5000 acres. Of land under lease one-fifth must be planted during the first five years, another fifth during the second five years, three-fifths in all during the first 20 years, and at least three-quarters during the remainder of the lease.

Pastoral leases may not exceed 30 years; the rental is 2½ per cent on the unimproved value, but during the first 10 years must not exceed 10s. per 1000 acres. The unimproved value is appraised every 10 years, and within the first 10 years for each square mile leased 20 head of cattle or 100 sheep must have been placed on the land.

History to 1914.—Early in the forties of the last century colonization was much discussed in German political circles, and in 1856 von Graeve advocated the establishment of German colonies in the South Seas—more particularly in the island of New Guinea, half of which at that time lay unclaimed by any European Power. But Bismarck, then German chancellor, was too much occupied with civil and military affairs to trouble himself with suggestions for colonial expansion. It seemed to him contradictory to talk of a German Empire overseas when the German Empire at home had not yet been firmly established. Most German statesmen supported the chancellor. As late as 1871 Bismarck told the Reichstag that Germany wanted no colonies; in the absence of a navy they would only

be a source of weakness. In 1878 the commander of the *Ariadne* annexed New Britain, but his action was repudiated by Bismarck, who also in 1880 rejected a scheme for colonizing New Guinea which was put to him by a deputation of influential Berlin bankers and merchants. Soon afterwards, however, a dispute with Britain over the Fiji Islands, and the annexation by other Powers of great tracts in Africa, influenced Bismarck to reconsider proposals for overseas expansion.

In 1867 the New South Wales government had asked the colonial office to annex New Guinea, alleging 'the increasing traffic between Australia and the Indian Isles, by way of the Torres Straits, which makes the possession of New Guinea by the British Empire a matter of highest importance to Australian colonists.' The colonial office refused either to annex, or to protect voluntary settlers in, New Guinea. Nevertheless in 1877 the discovery of gold there caused a rush of colonists from Australia, and in April 1883, fearing German aggression, Thomas McIlwraith (then premier of Queensland) ordered the annexation of all New Guinea east of the Dutch boundary. This act and its results are discussed under PAPUA. In the end Germany annexed the north-eastern coast of New Guinea and the Bismarck Archipelago in November and December 1884, and on 6 November Commodore Erskine hoisted the British flag at Port Moresby. In 1886 a definite boundary was delimited between the German and the English 'spheres of influence.'

Having acquired her colonies, Germany determined to use them not as locations for her surplus population but as sources of raw material for her industries. On 17 May 1885 the New Guinea Company was formally empowered to administer the newly annexed territories in the western Pacific, and the Reichstag voted 180,000 marks for their protection. But the company failed hopelessly in its attempts to govern, and in 1889 the German government had to resume the fiscal administration; a second attempt by the company, made in 1892-8, was equally unsuccessful, and in 1899 it sold its rights to the German government for four million marks and became merely a privileged trading company. It had from the first lacked prestige, and the many changes in its staff worked against efficient administration and control of the native population. In the islands it did better than on the mainland, but even there it was weak and unrespected; punitive expeditions against the inland tribes resulted in reprisals that damaged both missionary and trading interests, and the several missionary bodies quarrelled with each other and with the company. On 1 April 1899 the government took over control and divided the protectorate into (*a*) Kaiser Wilhelms Land—the New Guinea mainland—with headquarters at Friedrich Wilhelmshafen and sub-stations at Morobe and Aitape (which they knew as Eitape); (*b*) the Bismarck Archipelago, with headquarters at Herbertshohe and sub-stations at Kavieng (Kawieng) and Namatanai; (*c*) the northern Solomons, with a sub-station at Kieta. In 1910 the Carolines, Pelews, Marianne, and Marshalls (including Nauru) were absorbed in the New Guinea Protectorate. Under German administration the protectorate was not a success. Certainly the economic development of the commercial companies progressed, but individual efforts were more or less stifled. Gold had been discovered in the Bismarcks, but other minerals remained unexploited. Towards the end of 1913, however, exploration was seriously undertaken, and scientific investigations were begun in preparation for a progressive policy. Just before the declaration of war in 1914 oil had been prospected for unsuccessfully. In its dealing with the native races the German government was forced to use 'pidgin-English,' as the natives learnt this far more quickly than they could German.

The governor was appointed by the Kaiser, with wide powers, and had no local councils to assist him. Three officials took part in the general administration, and two superior judges were in charge of the judicial department. A technical department supervised public works and instituted scientific researches. The Protectorate was divided into seven administrative districts under the control of magistrates, and a system of village constables (luluais) was initiated somewhat similar to that in force in Papua; to each district was allotted a detachment of native police (nearly 500 in all) under white officials. Until 1890 the Protectorate was under the control of the German foreign office, but was then transferred to the newly-established colonial department. In 1902 an honorary advisory council was superimposed on the department, but five years later control was transferred to a newly-created colonial office with large and independent powers.

The Military Occupation.—On 12 September, 1914 the Australian Naval and Military Expeditionary Force (see AUSTRALIAN IMPERIAL FORCE) captured Rabaul, and five days afterwards terms of capitulation were signed by Colonel Holmes and Herr Haber, the acting-governor of German New Guinea. Military resistance to the occupation was to cease throughout the Protectorate (i.e. in the northern island-groups—now held under mandate by Japan—as well as in the region south of the equator) but Germans might remain in charge of their businesses and plantations. Military detachments were despatched to out-stations. When Holmes returned to Australia, Commander S. A. Pethebridge was appointed military administrator; on his death in 1918 he was succeeded by Brigadier-general G. J. Johnston, and he in 1920 by Brigadier-general T. Griffiths. Griffiths was transferred to Nauru (q.v.) on 3 February 1921, and Brigadier-general E. A. Wisdom became administrator. After the capitulation many Germans remained in official positions, but were gradually replaced by Australians. During the military occupation, the jurisdiction of the district officers was analogous to that of the former German officials, and most of the German laws were still enforced; taxes on business, the native poll-tax, and the customs tariff were continued in a slightly altered form; and native regulations were issued, based on a draft which the Germans had intended bringing into force in 1915.

Under the terms of surrender the German civil officials were returned to Germany, and officers of the regular army sent to Australia as prisoners of war; of the other German colonists, many were deported for military reasons, and others left voluntarily. In 1920 an expropriation ordinance vested the properties of German companies or subjects in a public trustee, and in 1921 they were transferred to a custodian of expropriated properties. A board was appointed to manage them pending sale or valuation. In 1919 a royal commission enquired into the affairs of the territory; a minority report suggested either the amalgamation of the ter-

ritorial public service with that of Papua or at least the appointment of a single administrator, but the majority report, recommending a distinct government for the Territory, was adopted by the Commonwealth government.

The Mandate.—On 9 May 1921 the territory south of the equator came under the control of the Commonwealth by a mandate from the League of Nations. Under this instrument 'The Mandatory shall have full power of administration and legislation over the territory subject to the present mandate as an integral portion of the Commonwealth of Australia, and may apply the laws of the Commonwealth of Australia to the territory, subject to such local modifications as circumstances may require.' Slave-trading is prohibited; forced labour is allowable only for essential public works, and must be paid for. Traffic in arms and ammunition is to be regulated by the convention of September 1919. Natives may not be supplied with intoxicants. No military training may be carried on except for local defence and police. No naval or military bases may be established in the Territory. Any form of worship may be practised, and all missionaries who are nationals of any state that is a member of the League of Nations are free to travel or reside in the Territory. No alteration may be made in the mandate without the consent of the council of the League of Nations, to which an annual report must be made. Any dispute between the Mandatory and another member of the League of Nations shall be submitted to the permanent court of international justice, if it cannot be settled by negotiation.

General Wisdom, then military administrator, was made civil administrator of the Territory. The administrator, who has no assistant legislature, is appointed by the Commonwealth; among the administrative departments are included the central court judges and the magistrates (district officers). The territory is divided into 11 districts, each in charge of a district officer, and some of them subdivided under deputy district officers. The districts are: Rabaul, Talasea, and Gasamata, in New Britain; Kavieng and Namatanai, in New Hanover and New Ireland; Manus, including the Admiraltys and the adjacent islands; Kieta, in the northern Solomons; and Morobe, Madang, Sepik, and Aitape on the mainland. A force of 500 native police is distributed among the districts to keep them under control and open up new country. The German system of luluais is continued. No legislative act of the Commonwealth has force in the Territory unless it is expressly so stated in the act. The governor-general has power to make ordinances having force of law in the Territory.

The expropriation board has gradually taken over German businesses and plantations, and repatriated most German civilians. In 1925 a few properties still remained unvalued. Except those to be resumed for administrative purposes, all will be offered for public sale by tender, and up to June 1926 130 lots had been sold, realizing £474,921—the official valuation was £397,159. Many returned soldiers who had been engaged on plantations as members of the board were among the successful tenderers. The sale marks a distinct advance in the economic progress of the Territory. As soon as the residue of the properties is sold the expropriation board will cease to function. In 1925 the federal parliament decided to appoint an advisory council to assist the administrator in his duties. The council embodies the directors of health and agriculture, the commissioner for native affairs, the government secretary, and the treasurer, and has power to propose new ordinances and recommend alterations and additions to the old.

Shipping.—The German Protectorate was well served by steamers. The Norddeutscher Lloyd ran monthly steamers between Hong Kong and Sydney, calling at Aitape, Madang, Rabaul, and Herbertshohe, as well as a direct service between Singapore and the main ports of the Territory. Smaller vessels plied between the plantations. Another shipping company—the Jaluit Gesellschaft—maintained a monthly service between Jabor (in the Marshalls) and Sydney, via Rabaul. The Mandated Territory is served by a single three-weekly service of steamers from Sydney and by 'tramp' steamers when sufficient cargo offers. Up to 1925 the Commonwealth navigation act applied to the Territory, but in that year its restrictions on territorial trade were cancelled.

Statistical.—In 1913 the exports of agricultural and marine products, feathers, and other minor commodities, amounted to £393,404. In 1924-5 the amount was £858,990, although bird-of-paradise feathers, which before the war accounted for many thousands of pounds, had become a prohibited export. The increase over 1913 is entirely due to copra—rubber, sisal hemp, cocoa-beans, bêche-de-mer, and ivory nuts all showing a decrease. In 1924-5 the territorial revenue was £242,775 and the expenditure £250,902; the revenue was derived chiefly from taxes and the customs tariff. The imports, including tobacco (over £43,000 worth), textiles, agricultural products, groceries, metals, and machinery, amounted in all to £537,940—a decrease of £30,821 on the previous year; the exports showed an increase of £87,643. At 30 June 1925 the native population in areas under complete control or government influence was 257,551, and the estimated population of areas patrolled but not under complete control 121,150. The white population was 1688 and Asiatics 1357.

Missions.—Six mission societies are established in the Territory. The (Catholic) Mission of the Most Sacred Heart of Jesus, with a staff of 105 Europeans, operates at Rabaul, Manus, and in New Ireland. At Madang is the Holy Ghost (Catholic) Mission, with a staff of 46. Twelve members of the Lutheran Mission are stationed at Morobe, Aitape, and Madang; the Methodist Missionary Society, with a staff of 18 Europeans, has stations at Rabaul and in Talasea, and New Ireland. The Marist Mission Society has 26 Europeans working in the Solomons, and the Liebenzeller Mission has a representative in Manus.

Relations with the Natives.—During the regime of the New Guinea Company and the early years of direct German administration, the policy was primarily to use the country and its aboriginal inhabitants for the benefit of Germany. As the *Kamerun Post* of 2 May 1914 said:—'Of what use is the native to us if he does not want work?' A poll-tax was levied to compel natives to go to work; but, rather than do so on European-owned plantations, the native preferred to sell his own produce, or to work for a coloured planter just long enough to earn the amount of the tax. Native labourers were therefore indentured from a few of the neighbouring islands and from the Solomons and Java, Asiatics being introduced as overseers.

Under this policy the economic development of the Territory had not progressed as far as it should, considering the amount of money that had been invested. In 1912 schemes were suggested for training the aboriginal inhabitants in skilled work, so as gradually to replace the Asiatics, but by 1914 these schemes were still more or less on paper, and little practical work had been done. Native youths, certainly, had been instructed by Malays in rubber-growing, with the intention of gradually producing a large crop of native-grown rubber, the price for which was fixed and guaranteed, so that the native should not be exploited by white traders. But in the government's dealings with natives the economical side was nearly always considered and the ethical seldom. The labourer's health, for instance, received attention, and a fine tropical medical service was inaugurated. Birching, caning, fining, or imprisonment of native labourers could be inflicted by European planters under authority from the German governor. These punishments have now been wholly transferred to the magisterial officers, and the birching and caning of natives is forbidden.

The native at his present stage is not as a rule capable of sustained effort, and must be taught and encouraged to plant, reap, and market his own goods; the Territory could thus be developed economically, without the wastage of European lives and energy on large plantations, and the tropical producer would deal with the consumer through the European merchant, as is done in the West African colonies. Since the mandate the administration has inaugurated schemes for general and technical education; an elementary school has been established for native children, and a technical school for training the more intelligent natives in handicrafts and domestic economy. A medical staff is engaged in stamping out the diseases introduced by European and Asiatic colonists, as well as the many local diseases.

Anthropology.—There is still a vast field for the anthropologist in the Mandated Territory, and the newly-created position of government anthropologist will be of great value to science. With our present knowledge not more than three main groups—negrito, Papuan, and Papuo-Melanesian—can be distinguished among the natives. The negrito is woolly-haired, brown-skinned, of medium to small stature (sometimes a pygmy), brachycephalic, with a platyrrhine nose, and inhabits the head-waters of the Sepik. Schultze has collected evidence of a pygmy element in the south-western ranges near the Papuan border. A less pure breed of negrito (with Papuan admixture) occurs in the Rawlinson and Sattelberg ranges on the Huon peninsula. Regarding the customs and social organization of the Sepik negrito little is known, but he seems to resemble the negritos of north-western Papua (q.v.).

More field-work has been done among the Papuo-negrito (Kai) tribes of the Huon peninsula. They are of mixed pygmy and Papuan descent, and speak a Papuan language. They have animistic beliefs, and at their circumcision festivals (which are held in a long tapering hut in the forest away from the village) bull-roarers are used. To assist the growth of crops religious games are played. According to Keysser, the soul of a person remains alive after death and resembles the living in shape, but can be degraded by ghost-sorcerers into an animal and again into an insect, with the death of which the soul-stuff disappears. The cuirass commonly associated with the negrito in the north-west of Papua has been found near the Bewani ranges and near the coast east of Humboldt Bay, but at present no negrito element is known in these regions.

The Papuan is black and woolly-haired, with a dark brown skin, dolichocephalic head, and long, broad nose—sometimes very prominent and convex. His main habitat is the interior of the mainland; he is also found near the coast at Monumbo (close to Potsdam harbour), along the Keram (the most easterly tributary of the Sepik), at Bogadjim near Astrolabe Bay, and at Sialum and Kwamkwam near Cape King William. He speaks a Papuan language, uses bull-roarers(at least in the district between Astrolabe Bay and the Huon Gulf), and prepares great ceremonial paraphernalia in connection with initiation and other festivals, more especially among the Sepik River tribes. In many inland districts head-hunting is practised, and there seems to be a skull-cult. Between the Sepik and Aitape the spear and spear-thrower are used; coiled pottery is manufactured along the middle Sepik. Huge carvings of the human form are prepared, but merely as a representation of the dead and not in connection with ancestor-worship.

The Papuo-Melanesian's hair is woolly, sometimes curly or even wavy. The colour of the skin varies from dark chocolate to copper. The head is usually dolichocephalic, though here and there the brachycephalic type is found. The nose is broad and often straight, but as a rule smaller than that of the true Papuan. Papuo-Melanesians are found on the mainland coast (especially round Astrolabe Bay and on the north coast) and inland up the Markham River. Among the islands of the Bismarck Archipelago the natives tend towards a purer Melanesian type as the distance from the New Guinea mainland increases. They show, however, many analogies to the Massim farther south, and are therefore included among Papuo-Melanesians until further field-work has allotted them their proper group. On the Admiralty Islands there seem to be three distinct groups of people—Manus, Matankor, and Usiai. The Manus live in houses on the sea, use canoes and large fishing-nets, understand the movements of the moon and stars, and chew betel-nut; they are head-hunters, and have probably a large amount of Papuan admixture. The Matankor build their houses on the shore and neither understand the moon and stars nor chew betel-nut. The Usiai are bush tribes who cultivate gardens; they are cannibals and snake-eaters, and are the most primitive in culture. Among their tribes many different dialects are spoken. In some parts of the Admiralty group kava-drinking is practised, and the slit-gong is used. Bows and arrows are now rare except in hunting, their place having been taken by spears and lances. These people appear to be totemistic.

South of the Gazelle peninsula in New Britain, the Sulka, Menga, and Tumiup tribes speak a non-Melanesian language. Among them are found initiation ceremonies, the practice of circumcision, boring the nose, blackening the teeth, and the chewing of betel-nut. Little is known of their social organization. The dead are buried in a house in a sitting position, and care is taken to protect the corpse from contact with the earth.

The Baining tribes of the Gazelle peninsula, who also speak a non-Melanesian language, are semi-nomadic agriculturists. There seems to be

no system of chieftainship, and—as is not the case with other tribes of the archipelago—the men can choose their own wives. The dead are interred, but the grave is sometimes left without any covering of earth.

In northern New Ireland and in New Hanover there is a system of totemic clanship. The people manufacture (and use in certain ceremonies) complicated masks and carvings. There are traces of an ancestor-cult, but no secret societies. Though platform-burial is still practised, the usual mode of the disposal of the dead is by cremation.

The next culture-district comprises southern New Ireland, the Duke of York group, the eastern coast of the Gazelle peninsula, and the western part of the north coast of New Britain. Here the tribes are divided into two exogamous moieties, in some parts associated with legendary heroes, in others with birds, insects, or even coconuts. Descent is matrilineal—except in the west of New Britain, where there is evidence of a change from matrilineal to patrilineal. Connected with the social groups are traces of totemism. In the Gazelle peninsula rank depends on riches (in the form of shell-money); in New Ireland and western New Britain there is a system of hereditary chieftainship, with succession in the male line. Of the two secret societies operating in this culture-district, the Ingiet is the older, but the more recent Dukduk is more prominent in public life. The former has many branches, but admission into one of them carries with it membership of the whole organization. Initiation is made by payment of shell-money, and is accompanied by a form of seclusion; at the end of the seclusion-period the initiate is presented with a small gift of shell-money by all present at the ceremony, the implication being that he has died and come to life once more. Only initiates may see certain stone images representing dead members of the society; these images may take human or animal form, and some are merely manufactured inanimate objects in which the ghost of the maker is supposed to reside. Celebrations of the Ingiet ritual are held at places lying successively from west to east in New Britain, Dukduk celebrations move similarly from east to west. The principal feature of the Ingiet society is the practice of magic, both beneficent and malignant; special initiation is required before members can practise malignant magic. In one branch of this society the annual initiation ceremony includes the erection of a strange pyramidal tower-like structure on the main branches of a tree. The Dukduk society initiates only male members, and at its ceremonies masks of two kinds—dukduk and tubuan—are used; the tubuan is presumed to remain alive throughout the year, the dukduk only for some months. The society seems to have a skull-cult, and the wearer of the dukduk uses a special secret cry. The ownership of a tubuan mask brings importance to the owner, who may protect private property by a taboo sign. During the society's dances bull-roarers are swung to warn off the uninitiated. In the Bismarck Archipelago the Dukduk cult seems to be associated with the solstice, and Rivers supposes it to be connected with some hidden cult of the sun. The shell-money used for initiations (obtained from *Nassa callosa* var. *camelus*) is also used in the transactions of everyday life.

In this culture-district interment is the usual way of disposing of a dead body, but in some areas corpses are thrown into the sea; platform-burial is also practised. The decorative art is based on spiral and other curvilinear designs. In the northern Solomons little is known about the bush and the mountain tribes. The coastal tribes have a Melanesian culture. In Bougainville cremation is practised, and there is an archaic system of relationship. Secret societies similar to the Dukduk have great power, and the bull-roarer is associated with them. Bird-totemism is found in this district; there is a belief in animal ghosts, and there seems to be a tree-cult, but little is known of it. Descent is matrilineal. The language is Melanesian. See MELANESIA, MIGRATIONS IN.

Of books dealing with the Mandated Territory the greater number are (as might be expected) German; the following are worth special study—Otto Finsch's *Neu-Guinea* (1865), C. Hager's *Kaiser Wilhelmsland und der Bismarckarchipel* (1886), R. Parkinson's *Im Bismarckarchipel* (1887), B. Hagen's *Unter den Papuas* and M. Krieger's *Neu-Guinea* (1899), H. Blum's *Neu-Guinea und der Bismarckarchipel* (1900), R. Parkinson's *Dreissig Jahre in der Südsee* (1909), R. Neuhauss's *Deutsch Neu-Guinea* (1911), and O. Reche's *Der Kaiserin Augusta Fluss* (1913). Among English books the *Autobiography* of George Brown, q.v. (1908), Evan Stanley's *Salient Geological Features of the Mandated Territory*, and the *Report* of the royal commission of 1919 should be consulted.

L.A.

Manganese. See MINERALOGY.

Mangrove, a name usually applied to species of Rhizophoraceae which thrive in saltwater marshes; it is also used for species of *Avicennia* (family Verbenaceae) and *Aegiceras* (family Myrsinaceae) from similar localities. For the milky mangrove see EXCAECARIA.

Rhizophoraceae are a small, almost entirely tropical family of trees and shrubs with opposite, leathery leaves and flowers in small clusters (occasionally solitary), found in Asia, Africa, and America. Several Asiatic genera are indigenous to Australia. Calyx-lobes 4-12; petals alternating with sepals; stamens inserted with the petals at the base of the free part of the calyx; fruit enclosed in the calyx-tube. The genera *Rhizophora, Bruguiera* and *Ceriops* are tropical, strand, or salt-marsh plants, whose seeds are in an advanced stage of germination (vivipary) when they fall from the trees. The elongated embryo becomes detached and falls, its lower end boring into the mud; after a few days the bud at the upper end—previously covered by the bell-shaped seed-leaf—is disclosed. Its four small green scales do not greatly enlarge, but the shoot arising from it develops the large foliage-leaves. Roots also arise from the lower end, though a true tap-root is not formed. The seedlings are capable of floating in salt water for a long time without injury, and are frequently carried long distances by ocean currents. This group of mangroves develops stilt-roots on the lower part of the stem, thus raising the trees to a considerable height above the mud.

Rhizophora includes three species, two in Asia and one in America. The calyx is divided, nearly to the base, into 4 segments; petals 4, entire; stamens 8-12, with short stalks; fruit oval or conical. *R. mucronata*, the only species indigenous to Australia, is the common tropical mangrove. Its bark is used in India for tanning; the Australian trees also contain tannin, but all mangroves increase in tannin-content as their habitat approaches the equator. Fijians use the blood-red sap for dying their hair, and (when mixed with the sap of *Hibiscus moschatus*) for painting crockery. The aerial roots are

elastic, and afford good material for bows. *Bruguiera* is widespread along tropical sea-coasts in the Old World. The calyx-tube is bell-shaped, with 10-15 narrow segments; fruit top-shaped, crowned by the persistent calyx-lobes. *B. Rheedii* (Red Mangrove, 'Kowinka' of the Queensland aborigines) has a hard durable timber, yellow or reddish-brown, close-grained and coarsely fibrous, useful for axe- and pick-handles. It is used in India for house-posts and furniture, and the bark for tanning. *Ceriops* is a small genus; the only indigenous representative, *C. Candolleana*, is a small tree or tall shrub with dense clusters of flowers. Its timber is used in India for the knees of boats and house-posts, and the bark as a litter for cattle.

Carallia, extending over tropical Asia, is not a strictly coastal genus, and its succulent globular fruit does not show vivipary. The single indigenous species, *C. integerrima*, is a small tree with diminutive flowers, 3-5 together on short branches. The wood is light-coloured, darkening prettily towards the heartwood, close in the grain and easy to work; it takes a good polish. It is used in Burma for furniture and building purposes.

Avicennia, a genus of the family Verbenaceae, contains a few species widely dispersed over the warmer regions of the globe; the single species indigenous to Australia is the commonest. The calyx is divided to the base in 5 distinct segments; corolla-tube short and broad, with 4 nearly equal spreading lobes; stamens 4, inserted in the throat of the corolla; fruit a compressed capsule; seed solitary, erect. *A. officinalis* (White or Gray Mangrove) is an umbrageous tree, always found near the sea. It forms forests in the mud-flats bordering salt-marshes, or lines the banks of tidal rivers, and is specially equipped for existence in this environment. The leaves have a varnished coat for protection against the sun's rays; to breathe, the tree has developed erect asparagus-like structures (pneumatophores or breathing-roots, found also in other mangroves) that rise from the horizontal roots, the marsh mud being imperfectly aerated. These organs project above the water at low tide and secure the necessary supply of oxygen. The fruits are adapted for distribution by currents, and, in a more or less advanced stage of germination, are borne to adjacent mud-banks where they quickly become established. The timber, on account of its toughness and interlocked tissue, is valuable for stonemasons' mallets; it is also used for knees of boats and bullock-yokes.

Aegiceras (family Myrsinaceae) is limited to a single species, spread over the sea-coasts of tropical Asia and Malaysia. *A. majus* (Black or River Mangrove) is a large shrub found in salt-marshes and tidal rivers along the Australian coast from New South Wales to northern Australia. It has fragrant flowers in clusters, which develop into bunches of horn-shaped fruits. Like some other mangroves, it is useful for consolidating the banks of saltwater rivers.

Manners-Sutton, Sir J. H. T. See Canterbury, Viscount.

Manning, John Edye (1807-1889), elder brother of Sir W. M. Manning (q.v.) was born at Bristol and migrated to New South Wales in the thirties with his father, who was appointed registrar of the supreme court. Having a gift for engineering, the son devoted himself to marine architecture, from 1835 onwards ran a small steam ferry (the *Experiment*) to Parramatta, invented in 1836 machinery for lifting engines from wrecks exposed to the sea, in the same year ran a locally built and engined steamer to the Hunter, in 1842 added the *Emu* to his Parramatta service, and in 1844 founded the Parramatta Steamboat Company. A few years later he founded the Illawarra Steam Navigation Company, and embraced the Clarence River district in his scheme of coastal navigation. Many of the vessels employed in these services were partly designed by him, and nearly all—whether built locally or in England—he supervised in the building. He died at Wentworth Falls in New South Wales on 24 February 1889.

Manning, Sir William Montagu (1811-1895), son of John Edye Manning of Bristol, was born at Alphington in Devon on 20 June 1811, educated at University College, London, and admitted to the English bar from Lincoln's Inn in November 1832. In 1837 he migrated to New South Wales to become chairman of quarter sessions. On 1 September 1844 he was made solicitor-general, and held the post until the advent of responsible government in 1856, with an interval (12 January 1848 to 19 November 1849) during which he acted as a judge in the absence of Judge Therry. On 13 October 1851 he was appointed to the legislative council, and took a considerable part in moulding the constitution bill of 1853. On 9 April 1856 he was elected by the south riding of county Cumberland to the new assembly, and became attorney-general in the Donaldson (June-August 1856) and Parker (October 1856 to May 1858) ministries, but retired on 25 May 1857 on account of ill-health; he took the same office in the Forster ministry of 1859-60, but held it only a few weeks and retired before he could secure a seat in the house. On 24 June 1861 he was nominated to the council, and remained a member till 1876, being attorney-general in the Robertson and Cowper ministries (31 October 1868 to 15 December 1870). On 28 April 1876 he was made a judge of the supreme court and primary judge in equity. Retiring on 17 October 1887, he devoted the rest of his life mainly to the university of Sydney—of which he had been made chancellor in 1878—and died on 27 February 1895. (Kt.Bach., 1858.)

Man-o'-war Bird. See Frigate-birds.

Mansfield, Ralph (1799-1880), born at Liverpool, England on 12 March 1799, was ordained a minister of the Wesleyan Church in 1820 and sent to Sydney to assist Samuel Leigh (q.v.). He ministered at Sydney (1820-2), at Parramatta and Windsor (1823), at Hobart (1824-5), and at Sydney again till 1828, when, owing to misunderstandings with the executive committee in London, he retired from ministerial work while retaining the title of 'Reverend.' He then entered on a journalistic career—no strange thing for him, since in 1821-2 he had joined Carvosso and Lawry in conducting the *Australian Magazine*. From 1829 to 1832 he edited the *Sydney Gazette;* in 1833 he started the *New South Wales Magazine*, with the eccentric Dr. John Lhotsky as co-editor; he contributed many articles both to Dr. Lang's *Colonist* and to the *Sydney Morning Herald*. In the same year he became a bookseller, specializing in second-hand medical works and serial romances, and binding books as a side-line; but he sold the business in 1834 to G. W. Evans (q.v.). In 1836 he advo-

cated the lighting of the town with gas, formed a company for the purpose, and was its secretary until his death in June 1880. In 1841 and 1846 he published 'analytical views' of the census taken in those years, the first purely statistical work published in Australia, and a distinctly valuable ancestor of the *Year Books* of recent times. J.C.

Mantis, vernacular name of insects of the family Mantidae, belonging to the order Orthoptera. The true Praying Mantis (*Mantis religiosa*) is not found in Australia, where the order is represented by about 80 species, some of them large and handsome. The common green species is *Orthodera ministralis*; a large, short-winged

Archimantis latistylus.

mantis (*Archimantis latistylus*) and the handsome, elongate *Tenodera australasiae* are also well known, and the small, active, tree-haunting species of the genus *Paroxypilus* and its allies (belonging to the sub-family Perlomantinae) are not uncommon. The remarkable front-legs of these insects are specially constructed for holding their prey, the family being carnivorous and highly voracious. Sharp (*Cambridge Natural History*) records from Victoria the utilization of this voracity in the young mantis for clearing a room of flies by placing them on the window-blinds of houses. See ORTHOPTERA. R.J.T.

Manucode. See RIFLE-BIRDS AND TRUMPET-BIRD.

Manufactures. During the early years of settlement supplies from England were received irregularly and at long intervals; it was necessary, therefore, for the colony to be self-supporting as far as possible. In addition to industries associated with agriculture (e.g. flour-milling) attention was given to the manufacture of cloth. In 1790 Andrew Hume (father of Hamilton Hume, q.v.), an expert in the manufacture of flax, was appointed superintendent of convicts on Norfolk Island, and began experiments with the local flax-plant; early in 1791 two pieces of indifferent cloth were made, but the experiment was not continued. European flax was then planted in the neighbourhood of Sydney, looms sent out by the British authorities were set up at Parramatta under the supervision of an Irish convict, and by March 1802 646 yards of linen and 306 yards of woollen blanketing had been made; by March 1804 sufficient sacking was being made to meet agricultural requirements, and 50 yards of linen were bartered weekly by the commissariat; only coarse wool could be procured, the better grades being bought up by Yorkshire. The government cloth-factory at Parramatta was maintained for the greater part of the convict era, but the manufacture of linen was gradually abandoned. Macquarie encouraged private enterprise, and during his administration Simeon Lord (q.v.) initiated the manufacture of cloth at Botany; he also planned to form a settlement in New Zealand to procure supplies of flax, but this venture was a failure. Early in the forties Sir John Jamison (q.v.) erected cloth-mills near Penrith, but the development of the wool trade ensured a regular shipping service and cheap supplies of cloth from overseas.

The first ale brewed in Australia was made by James Squire at Kissing Point on the Parramatta River in 1795, but he did not work continuously, though in 1819 he described himself as a licensed brewer of many years' standing. King in September 1804 established a government brewery at Parramatta, but in March 1806 leased it to Thomas Rushton and in May licensed Andrew Thompson to brew beer for settlers on the Hawkesbury. Maize was the grain generally used. In March King also leased to Michael Burn the salt-pans at Rushcutter's Bay, but maintained those at Newcastle under government control, and a little later established fresh pans at Rose Bay. In 1807 table-salt was prepared at John Blaxland's private pans on the Parramatta and at Newcastle, but salt for curing was mainly imported—though Bligh declared that the Rose Bay salt was 'now produced in tolerable perfection.' Under Macquarie and his immediate successors manufactures lagged, the attention of both governor and colonists being concentrated on the spread of settlement and the production of wool and wheat. Bigge discouraged manufactures, since in his opinion convict labour could be much more usefully employed by settlers in farming and wool-growing. The only factory of which he took any notice was Lord's, where cloth, hats, blankets, and stockings were being made—'the Colonial-made goods, however, are still so costly that it is more economical to buy imported wares.' Nevertheless before the thirties other articles were being manufactured on a small scale—good soap made with soda from Botany Bay mangroves; enough candles to supply the local market; tanned leather; tobacco (q.v.); cheese 'of the best quality;' and coarse earthenware, the best-known potteries being those of James King (q.v.) of Irrawang. There were also nascent shipbuilding and wine-making industries, which are separately described. But capital was better employed in pastoral enterprises and before the gold discoveries manufactures were few and unimportant. In 1848 the number of industrial establishments in Australia was only 479, and of persons employed under 2000; the most numerous of any one class were flour-mills, of which there were 220. Next in number were establishments for the treatment of skins and hides, followed in the order named by breweries and distilleries, soap and candle works, iron foundries, brick-works and potteries, and boat-building. Of the 479 establishments 272 were in what is now New South Wales, 41 in the Port Phillip district (now Victoria), 99 in Tasmania, and 67 in South Australia. The average number of employees was less than five.

The discovery of gold effected a revolution in all industrial relations. Many migrants who arrived during the gold-rush, failing for one reason or another to meet with early success on the goldfields, settled down to the trades or occupations they had previously followed. At a later stage the depletion of the richer alluvial deposits threw many diggers out of employment, and population began to concentrate in a few of the larger towns, establishing incipient artisan communities. The manufacturing industries therefore owe their development very largely to the population which was attracted to the country by the gold-discoveries.

The construction of the first railways (1854) and the re-establishment of regular steamship communication with Europe (1856) helped to encourage this nascent industrial activity. New South Wales and Victoria, which in 1855 received the benefits of responsible government, soon turned their attention to the settlement of an agricultural population on the land, thus increasing the measure of primary production and promoting the development of manufactures. Since the inauguration of the Commonwealth, the throwing open of all Australian markets to the produce of each State has facilitated the internal distribution of Australian products; there has been very substantial development in manufacturing industries, and many of them are now established on a secure basis. The development since 1911 is indicated by the following figures:—

Development of Manufacturing Industries in Australia, 1911 and 1924.

	1911	1924
Number of factories ..	14,445	20,189
Number of employees .	311,772	429,990
Wages paid	£27,532,000	£77,278,000
Value of fuel used ...	£2,753,000	£10,297,000
Value of materials used	£79,041,000	£197,039,000
Value of output	£133,186,000	£348,578,000
Value added in process of manufacture	£54,145,000	£141,241,000
Value of land and buildings	£32,499,000	£82,562,000
Value of plant and machinery	£31,599,000	£99,553,000

The value added in process of manufacture best represents the net wealth created by manufacturing operations. The increase in this value since 1911 is equivalent to an average annual increase of slightly over 20 per cent.

The greatest development in manufactures has naturally taken place in the more populous States. In 1924 about 73 per cent both of the factories and of the employees were in New South Wales or Victoria:—

FACTORIES AND EMPLOYEES IN EACH STATE, 1881 TO 1924.

Year.	New South Wales.	Victoria.	Queensland.	South Australia.	Western Australia.	Tasmania.	Commonwealth.
			Number of Factories.				
1881	2,961	2,488	571	823	...	...	...
1901	3,367	3,249	2,110	1,335	662	420	11,143
1921	5,837	6,532	1,795	1,438	895	616	17,113
1924	7,321	7,289	1,912	1,698	1,188	781	20,189
			Number of Employees.				
1881	31,191	43,209	...	10,995	...	...	...
1901	66,135	66,529	26,172	19,283	12,198	7,466	197,783
1921	145,011	140,743	43,196	30,430	17,034	10,225	386,639
1924	159,674	156,162	44,948	37,275	19,712	12,219	429,990

The next table summarizes the official statistics for 1923-4 for the various groups of industries. It will be seen that as regards net wealth created (i.e., value added in process of manufacture) the most important industries are those connected with metal-works and machinery.

The largest number of employees was engaged in the clothing and textile industries, which occupied 23.4 per cent of the whole number. Classes VI, VII, and VIII comprise the industries in which female labour is largely employed.

The maximum amount of salaries and wages was paid in Class V—24.4 per cent of the total amount.

COMMONWEALTH MANUFACTORIES, 1923-4.

Class of Industry.	Establishments.	Hands Employed.	Salaries and Wages Paid.	Value of Land and Buildings Used.	Value of Plant and Machinery.	Value of Raw Material, Fuel, and Light Used.	Value of Output.	Value added in Process of Manufacture.
	No.	No.	£	£	£	£	£	£
I. Treating raw material, product of agriculture and pastoral pursuits.	799	10,342	1,966,000	2,085,000	2,171,000	15,558,000	19,181,000	3,623,000
II. Treating oils and fats (animal, vegetable, &c.)	99	3,424	606,000	953,000	1,147,000	3,035,000	4,647,000	1,612,000
III. Processes in stone, clay, glass, &c....	845	20,256	4,306,000	3,592,000	5,463,000	4,401,000	12,155,000	7,754,000

IX. Musical instruments, &c.	50	1,357	298,000	254,000	94,000	396,000	848,000	452,000
X. Arms and explosives	15	803	188,000	298,000	253,000	212,000	491,000	279,000
XI. Vehicles and fittings, saddlery, harness, &c.	2,189	22,490	3,902,000	5,167,000	1,278,000	4,195,000	10,414,000	6,219,000
XII. Ship and boat-building and repairing	88	5,794	1,443,000	1,790,000	2,045,000	701,000	2,332,000	1,631,000
XIII. Furniture, bedding, and upholstery	1,160	15,230	2,540,000	2,499,000	674,000	4,044,000	7,970,000	3,926,000
XIV. Drugs, chemicals, and by-products.	323	7,215	1,378,000	2,352,000	2,094,000	5,036,000	8,684,000	3,648,000
XV. Surgical and other scientific instruments	84	608	104,000	221,000	46,000	102,000	287,000	185,000
XVI. Jewellery, time-pieces, and plated ware	258	2,447	421,000	621,000	147,000	461,000	1,138,000	677,000
XVII. Heat, light, and power	435	12,967	3,229,000	6,103,000	25,030,000	5,780,000	14,750,000	8,970,000
XVIII. Leatherware, n.e.i.	126	2,576	382,000	394,000	107,000	830,000	1,470,000	640,000
XIX. Minor wares, n.e.i.	113	4,390	789,000	860,000	925,000	1,580,000	2,761,000	1,181,000
Total	20,189	429,990	77,278,000	82,562,000	99,553,000	207,336,000	348,577,000	141,241,000

In the next table particulars are given of the average annual earnings per employee in 1911 and 1924. In considering this table regard should be paid to the nature of certain industries which are carried on to a greater extent in some States than in others. In Victoria, for instance, there is a large number of factories and hands employed in the clothing industries, and in that class the average wages are low, a great many women and children being employed.

The average annual earnings per employee increased from £77 in 1907 to £92 in 1911, £111 in 1916, £169 in 1921, and £188 in 1924.

MANUFACTURING INDUSTRIES—AVERAGE ANNUAL EARNINGS PER EMPLOYEE, 1911 AND 1924.

Year	New South Wales.	Victoria.	Q'land	South Australia.	West Australia.	Tasmania.	Commonwealth
	£	£	£	£	£	£	£
1911	96·3	83·4	87·1	99·6	129·8	84·4	92·2
1924	194·1	184·8	179·2	188·2	190·2	163·6	187·6

The next table shows the value of production in manufacturing industries in each State—that is, the difference between the total value of the output and the value of the raw material used. In this respect New South Wales and Victoria far outstrip the other States, the value in New South Wales being 39.4 per cent of the total for the Commonwealth, and the value in Victoria 34.7 per cent of the total. Queensland's production amounted to 11.3 per cent, South Australia's to 7.9, Western Australia's to 4.0, and Tasmania's to 2.7. Comparing the third column of the next table with the last line of the previous one, it is seen that on the average wages accounted for nearly £188, or 57.3 per cent of the 'value of production per employee' (£328). This leaves approximately £140 per employee for profit, interest on capital, depreciation, fuel and light, and all other charges.

The value of production per employee increased from £173 in 1911 to £286 in 1921, and £328 in 1924—an increase of nearly 90 per cent between 1911 and 1924. But the increase in average annual earnings between 1911 and 1924 was approximately 103 per cent, which is considerably higher than the rate of increase in value of production per employee over the same period.

MANUFACTURING INDUSTRIES—VALUE OF PRODUCTION, 1924.

State.	Total.	Per Employee.	Per head of Mean Population.
	£	£	£
New South Wales ...	55,661,000	349	25
Victoria	48,901,000	313	30
Queensland ...	16,049,000	357	20
South Australia ...	11,179,000	300	21
Western Australia ...	5,698,000	289	16
Tasmania	3,754,000	307	17
Commonwealth...	141,242,000	328	25

As the total value of production of manufacturing industries in 1924 was £348,577,000, there remained—after payment of £197,039,000 for raw material, of £10,297,000 for fuel and light, and of £77,278,000 for salaries and wages—£63,963,000 to provide for all other expenditure, depreciation, interest, and profits. The figures, with the corresponding percentages, are shown in the following table:—

MANUFACTURING INDUSTRIES—DISTRIBUTION OF COSTS, 1924.

Particulars.	Total Amount.	Per cent on Total Value of Output.
	£	Per cent
Raw materials used	197,039,000	56·53
Fuel and light	10,297,000	2·95
Salaries and wages	77,278,000	22·17
All other expenditure, interest, and profits	63,963,000	18·35
Total value of output ...	348,577,000	100·00

From about 1911 to 1921 there was a substantial diminution in the percentage available for profits, interest and other charges; in 1911 the percentage was 17.9, by 1917 it had decreased to 16.2, and by 1921 to 14.66. During the next three years, however, the percentage increased again, and in 1924 was 18.35.

Out of 429,990 hands employed in manufactories in 1924, 107,033 were females and 322,957 males. In New South Wales the ratio of females to males was about one to seven in the year 1886; in 1891 one to six; in 1903 it became about one to four; and is now less than one to three. In Victoria the ratio of females to males during 1886 was about one to five; five years later (1891) it was somewhat less, but in 1896 had increased to about one to three, and in 1924 was nearly one to two. In the remaining States the ratios during 1924 were—Queensland and South Australia one to four, Western Australia and Tasmania about one to five. The proportion for the whole Commonwealth was one to three. The development of the clothing and textile industries is one of the main causes of increase in female employment. Certain trades are specifically considered women's trades—clothing and textile trades, preparation of food, book-binding, and lighter work connected with the drug trade. A considerable number of women are also employed as clerks and typists in factories.

In statistical compilations the term 'child' denotes any person under 16 years of age. Since 1907 there has been in every State an increase in the average number of children employed, and the total number of children employed in factories increased from 14,622 in 1907 to 21,209 in 1924. In each State, however, a comparison between the number of child-workers and the total number of persons employed shows a fairly regular decrease in the percentage of child-labour. For the whole Commonwealth this percentage decreased from 5.9 per cent in 1907 to slightly under 5 in 1924. The number of male and female children employed in factories in each State in 1924 was:—New South Wales, 8166; Victoria, 7479; Queensland, 2208; South Australia, 1972; Western Australia, 730; and Tasmania, 654.

To make the above information more complete, it should be supplemented by details exhibiting the development of individual industries; it is not possible, within the limits of this article, to give anything like a detailed account of Aus-

tralia's manufacturing industries, but the following table shows in summarized and comparative form particulars for 1924 regarding industries of special importance:—

Class of Manufactory.	Factories.	Employees.	Value of Raw Materials and Fuel used.	Salaries and Wages.	Total Value of Output.
	No.	No.	£	£	£
Tanneries	166	4,845	3,720,000	965,000	5,476,000
Soap and candles	70	2,556	1,808,000	439,000	2,915,000
Agricultural Implements ...	160	5,584	1,506,000	1,126,000	3,132,000
Engineering works, &c.	1,343	33,052	14,072,000	6,949,000	24,151,000
Railway workshops, &c. ...	122	25,130	4,757,000	5,799,000	11,652,000
Smelting works, &c.	38	5,780	12,572,000	1,586,000	17,384,000
Bacon-curing	73	1,523	3,477,000	349,000	4,399,000
Butter, cheese, &c.	583	5,233	16,792,000	1,112,000	19,526,000
Ice and refrigerating, &c. ...	311	2,313	4,712,000	469,000	5,775,000
Jam and fruit preserving, &c. ...	175	6,600	3,002,000	885,000	4,722,000
Confectionery	258	8,724	3,445,000	2,263,000	6,163,000
Flour-mills	182	3,697	13,371,000	845,000	15,867,000
Sugar-mills	40	6,000	5,453,000	1,075,000	7,754,000
Breweries	57	3,854	2,985,000	1,063,000	6,887,000
Tobacco, cigars, and cigarettes ...	28	4,312	4,519,000	806,000	6,645,000
Woollen and tweed mills ...	47	7,532	2,952,000	1,770,000	4,864,000
Boots and shoes	1,030	21,464	4,900,000	3,295,000	9,899,000
Coach and waggon building ...	707	5,706	1,100,000	918,000	2,459,000
Furniture and cabinet-making ...	774	10,201	2,311,000	1,786,000	5,046,000
Electric light and power ...	288	5,488	2,279,000	1,424,000	7,213,000
Gasworks	121	5,481	2,329,000	1,386,000	5,647,000
Chemicals, drugs, and medicines	143	3,132	1,628,000	533,000	3,138,000

Tanneries.—Until recent years the production of the tanneries in Australia was confined to the coarser classes of leathers, but lately the tanning of the finer skins has been undertaken with satisfactory results. In 1924 the number of hides treated at Australian tanneries amounted to 1,574,000, and the quantity of bark used to 29,000 tons; nearly 52,000,000 lb. of leather, valued at £3,814,000, were produced, in addition to 3,613,000 lb. of basils valued at £377,528.

Soap and Candles.—These two industries are frequently carried on in the same establishments, the total value of the output from Commonwealth factories in 1924 being approximately £2,915,000. The tallow used in that year was 435,000 cwt., of alkali 141,000 cwt., and of coconut-oil 739,000 gallons. The soap manufactured amounted to 883,000 cwt., the candles to approximately 9¾ million lb.

Agricultural Implements.—The manufacture of agricultural implements is an important industry in Australia, and is of particular interest owing to the fact that it was one of the first industries to which the so-called 'new protection' (q.v.) system was sought to be applied. The articles manufactured include strippers, stripper-harvesters, stump-jumping and other ploughs, harrows, disk and other cultivators, winnowers, baggers, drills, and other implements. Several Australian makers have built up a considerable export trade. The stripper-harvester, which combines the stripper with a mechanism for winnowing and bagging grain, is an Australian invention (see McKAY, H. V. and RIDLEY, JOHN) and is exported to many countries.

Engineering Works.—This group includes a considerable variety of important industries, the progress of which during recent years has been rapid. In addition to engineering works which supply ordinary requirements, a number of establishments engage in the manufacture of special classes of machinery and materials—e.g. internal-combustion-engines, high-speed steam-engines, weldless steel tires, water-meters, weigh-bridges and weighing machinery, stamped metal work, tractors, power-plant transmission, steel castings, boiler-making, air compressors and mining plant, aluminium ware, refrigerating engines and ice-making machinery, copper tubes, cycles, and motor-cycles, art metal, axles, wheels, bolts and nuts. The manufacture of iron and steel is an industry which since the outbreak of war has made rapid progress, and has been the means of establishing many subsidiary industries, such as wire-drawing, nail-making, and the manufacture of railway rails and fishplates.

The manufacture of mining and smelting machinery is also an important section of the engineering industry. Much of it is of Australian invention, but some is manufactured under licence from holders of British and American patents.

Railway Workshops.—The railway workshops of Australia are chiefly State institutions. The extension of the railway and tramway systems, jointly with increased traffic, has greatly stimulated the manufacture of rolling-stock, etc., though during the war period the operations of these establishments were restricted on the score of economy. The value of the output increased from £5,037,000 in 1918 to £11,652,000 in 1924.

Smelting Works, etc.—This group includes establishments for metal-smelting, the manufacture of cyanide and pyrites, and metallurgical work. The metals manufactured in Australia include electrolytic zinc; soft pig-iron; refined assay, super-refined antimonial, corroding, and chemical lead; bar, sheet, and granulated silver; antifriction metal; type metal; assay and industrial litharge; copper concentrates; zinc concentrates; zinc dust; spelter; etc. The zinc industry is one of the most recent to be established in Australia, but there are already on the market locally-produced metallic zinc, in sheets of all gauges, and in other forms for a variety of purposes, zinc oxides and lithopone, zinc-lead pigment, zinc chloride, which is extensively used for the preservation of timber and in certain textile industries, and zinc sulphate.

Bacon-curing.—In 1924 the production of bacon and hams was over 62 million lb. valued at £3,697,000, and of lard over 2¾ million lb. valued at £107,000. The number of pigs killed in these establishments was 673,000. See PIGS.

Butter, Cheese, and Condensed Milk Factories.—The average annual production of butter in 1920-23 was over 234,000,000 lb., and the exports for the same period averaged 91,389,000 lb. Cheese manufactured in 1924 amounted to 24,000,000 lb. valued at £1,027,000. Before

1911 small quantities of condensed and concentrated milk and powdered milk were made, but in 1911 the output was nearly doubled; since then the industry has developed rapidly, and in 1924 the output was over 64,000,000 lb., valued at £1,964,000, and condensed milk, etc., to the approximate value of £1,000,000 was exported. The milk used at butter factories in the same year amounted to over 445,000,000 gallons; for the manufacture of cheese nearly 24,500,000 gallons were used, and for condensed milk nearly 17,000,000 gallons.

Ice and Refrigerating Works.—Large freezing-works have been installed in many parts of the Commonwealth for freezing products, chiefly for export. In 1924 over 4,000,000 lb. of frozen mutton and lamb, 105,000,000 lb. of beef, and 3,500,000 pairs of rabbits were exported.

Sugar-mills.—The cane-crushing branch of the sugar-making industry is carried on in Queensland and New South Wales, the only States in which sugar-cane is grown. From the mills raw sugar is sent to refineries in different parts of Australia for further treatment. Part of the molasses produced is used for the distillation of alcohol, part is turned into food-cake for cattle, and part is used for other purposes, but a very large quantity is run to waste. In 1924 the production of raw sugar was 286,000 tons, and of molasses 11,800,000 gallons.

The establishment of the sugar-refining industry considerably antedates that of the sugar-milling industry. The raw material was originally brought from the Mauritius and the East. In 1924 there were two refineries in Victoria, two in Queensland, one in New South Wales, and one in South Australia. At the six refineries approximately 296,000 tons of refined sugar, valued at £10,870,000, were made. See SUGAR.

Confectionery.—This industry has expanded considerably during recent years, largely as a result of the stimulus afforded by the embargo placed on the importation of luxuries during the war. Several oversea firms which previously exported largely to Australia have established factories in the Commonwealth. Since 1911 the number of confectionery factories and persons employed therein has increased nearly three-fold.

Breweries.—The main feature in the history of the brewing industry, which was established at an early date in Australia, has been a change from the small local brewery in every township of moderate size to the large, centralized, city brewery. Of the total acreage put down in barley in 1923-4 more than 84 per cent was sown with the malting variety. Hop-growing is profitable, particularly in Tasmania. The total quantity of ale and stout brewed in Australia amounts to approximately 66,000,000 gallons annually.

Tobacco, Cigars, and Cigarettes.—This was one of the first industries to be established in Australia (see TOBACCO), and the market has for many years been largely supplied by local manufacturers. Despite inducements held out to growers both by the government and by tobacco-manufacturing companies, the quantity of leaf produced locally is relatively small. In 1924 the quantity of Australian leaf used was only about 1½ million lb., as against nearly 16 million lb. of imported leaf. In 1924 the quantity of tobacco manufactured in the Commonwealth was over 14,000,000 lb.; about 431,000 lb. of cigars and over 4¾ million lb. of cigarettes were also manufactured.

Woollen and Tweed Materials.—Though Australia is one of the largest wool-growing countries in the world, only within recent years has the manufacture of woollen and textile goods been undertaken on any considerable scale. The industry was first started in a substantial way at Geelong, and this centre soon became famous for its tweeds; it is still the largest woollen-manufacturing centre in Australia, having five mills. During the war the Australian mills were for a time unable to supply the requirements of the Australian Imperial Force, although civilian trade was completely cut out; mills were therefore enlarged wherever practicable. During 1924 47 mills turned out nearly 5,000,000 yards of tweed and cloth and 7,600,000 yards of flannel, in addition to approximately 1,200,000 blankets and rugs. See WOOL.

Boots and Shoes.—This industry has for some years employed over 21,000 persons, nearly 60 per cent of them in Victorian factories. The output has also been steady, rising only from 12 million pairs in 1919-20 to 12½ million in 1923-24, although the number of factories rose in the same period from 532 to 1030; but most of the additional factories are concerned with repairs only.

Coach and Waggon Building.—In 1917 the importation of motor-car bodies was considerably restricted, primarily as a war-measure to conserve shipping space; a remarkable development of the local motor-car body-building industry ensued, and several firms have by standardizing their output reduced its cost and improved its quality.

Furniture and Cabinet-making.—Well-equipped factories exist in all the States, and the total output is valued at nearly 2¾ million pounds. Very little furniture is now imported, and Australian timber is in great demand, particularly for cabinet-making.

Gas and Coke Works.—In 1924 these works used 2,095,000 tons of coal, producing 17,500,000 feet of gas and nearly 1,750,000 tons of coke. Since 1914 many of them have begun to specialize in the recovery of by-products.

The value of production of manufacturing industries from 1906 to 1924-5 is shown in pounds sterling in the following table:—

1906 ..	31,172,000	1920–1 ..	101,778,000
1910 ..	48,100,897	1921–2 ..	112,517,000
1914 ..	59,004,000	1922–3 ..	123,188,000
		1924–5 ..	140,552,000

The following table further shows development of manufacturing industries:—

Year.	Hands employed	Salaries and wages paid (*a*).	Value of land and buildings used.	Value of plant and machinery.	Value of raw material, fuel and light used.
		£	£	£	£
1906	228,560	13,207,159 (*b*)	20,939,675	23,285,208	(*c*)
1910	286,831	23,874,959	29,506,054	28,976,735	75,394,572
1914	332,579	34,090,428	39,097,781	41,411,922	103,085,466
1920–1	386,639	62,931,718	60,831,468	68,655,270	213,555,770
1922–3	412,410	71,133,152	74,381,308	86,081,910	194,742,278
1923–4	429,990	77,278,000	82,562,000	99,553,000	207,336,000

(*a*) Excluding all amounts drawn by working proprietors. (*b*) Not including Queensland and South Australia. (*c*) Details too incomplete for publication.

The report of the Commonwealth tariff board for 1924-5 states that many conditions under which Australian manufacturers work are peculiar to this country, and place them at a disadvantage in competition with imported goods. Among these conditions are higher wages, shorter hours, payment for holidays, high cost of materials, limited market, and restricted production. In spite of these difficulties substantial expansion has taken place, and many new

industries have been recently established. Among the expanding industries are those dealing with paints and varnishes, hosiery, and knitted goods, glue and gelatine, rubber manufactures, confectionery, motor-car bodies, and shirts and collars. Among those recently established or in process of establishment are industries dealing with wire rope, telephone cables, oil-refining, railway-signalling apparatus, sewing threads and cotton, paper-pulp, gramophone records, cotton yarns, towelling, sheep-dip, water-tube boilers, storage-batteries, sheet-glass, thermionic valves, motor-generators, electric switch-gear, transformers and corsets. G.L.

Manures. Under this term are included all substances that increase crop-production by acting as plant-food. Natural manures are dung and farmyard manure, guano, blood, bones, hair, wool, seaweed and similar substances. The principal artificial manures are dried blood and bone-dust, meat-offal, superphosphate, sulphate of ammonia, potash salts, nitrate of soda, basic slag, lime and other substances which have undergone special treatment. The distinction is not always a very sharp one; substances like blood and bones are rarely used in their natural state, blood being as a rule artificially dried, and bones pulverized into bone-dust or bone-meal. On the other hand substances like kainit, gypsum, carbonate of lime, phosphate-rock and nitrate of soda, although they are minerals and used just as they come from the mine (except that they are more or less pulverized), come under the designation of artificial manures. The definitions given above are not identical with those employed in Australian legislation. When plant-feeding came to be studied scientifically, it was found that the beneficial effect of manures on plant-growth is due to the presence of three or four chemical elements—nitrogen, phosphorus, potassium and calcium; other ingredients of manure (e.g. water, carbonaceous organic matter, silica and saline matter), though beneficial to the soil from a mechanical point of view, either contribute little to the direct nourishment of the plant or are already present in the soil in sufficient quantities to render their addition unnecessary. We thus arrive at the following recognized classification of manures, based on the particular fertilizing ingredient which they provide:—(1) *nitrogenous* manures, which contain nitrogen either as organic nitrogen (such as blood, bone and offal manures), or in the form of ammonium salts (such as sulphate of ammonia), or in the form of nitrates (such as nitrate of soda); (2) *phosphatic* manures, which contain phosphorus in combination as a phosphate, generally phosphate of lime (such as rock-phosphate and superphosphate); (3) *potash* manures, which contain potassium as a potash salt (such as kainit, sulphate of potash, potassium chloride); (4) *calcareous* manures, which contain calcium in the form of lime or one of its salts (stone-lime, carbonate of lime, gypsum or sulphate of lime). Each of these ingredients has its definite function in plant-metabolism, but the functions are still somewhat obscure. It is generally recognized that nitrogenous manures promote the growth of leaf and straw, and produce a healthy green colour in the foliage. Phosphatic manures appear to encourage root-production; under Australian conditions they are most widely employed to promote vigorous growth of all crops, and, in the form of superphosphate are considered essential to the production of wheat and other cereals. Potash manures favour the formation of carbo-hydrates (such as sugar and starch), and are of special benefit, if not essential, to the successful growth of fruit and root-crops. Manures containing lime are more often used as soil-ameliorants than as direct plant-food. The special functions of lime are sweetening sour soils and lightening stiff clays. Many crops, however, are lime-lovers, e.g. lucerne and other leguminous crops, and grape-vines.

Although certain crops benefit by the application of a single fertilizing substance, a mixed manure containing all the above-mentioned plant-foods gives the best result, especially over a series of years; the most notable exception to this rule is wheat, which actually yields better when superphosphate alone is applied than with a 'complete' manure. Mixed manures are supplied locally to suit different crops and different classes of soil. Farmyard manure is a 'complete' manure, as it contains the four essential plant-foods, though in small quantities. Manures containing organic nitrogen are produced principally at abattoirs and meat-works, the blood and offal being either worked up or sold to manufacturers. Farmyard manure, bones, guano, fish-scrap, etc., also contain nitrogen in the organic form. These organic manures contain a certain amount of animal or vegetable matter which by its decomposition adds to the humus content, and incidentally increases the water-holding capacity of the soil; they are also less soluble in water than the inorganic manures mentioned later, and are consequently slower in their action. The beneficial action, however, is more permanent; the effects of a dressing of farmyard manure, for example, will persist for a considerable time. Some organic manures are more active than others, according to the rate at which they undergo fermentation in the soil. Fresh urine or blood is almost as readily available as an inorganic manure, whereas substances like horn-meal, hair and wool, or leather refuse, resist decomposition for a very long time. The order of solubility is roughly as follows:—fresh urine, dried blood, dried and ground flesh and offal, guano, fine bone-meal, oil-cake, fish-scrap, dung, coarse bone-meal, horn-meal, hair and wool, leather scrap. Those at the end of the list are often treated with sulphuric acid, just as bones are treated in the manufacture of superphosphate; this increases their solubility and converts them into comparatively quick-acting manures. Organic manures also differ considerably in their nitrogen content. Substances like dried blood, dried flesh, fish-scrap, etc., contain on the average 11 to 13 per cent nitrogen, or even more; farmyard manure does not contain more than ½ per cent.

Inorganic nitrogenous manures consist of saline matters derived from mineral substances, and contain no humus-forming material. The contained salts are very soluble in water, and are thus immediately available to plants; being readily washed down into the subsoil, they are most beneficial when applied in small quantities to the growing plant. Among inorganic manures of Australian manufacture the principal is sulphate of ammonia, derived from the ammoniacal liquor produced at gas-works; it is a white crystalline powder when pure, and contains about 20 per cent of nitrogen in combination. Very soluble in water, it is immediately available as plant-food, and is on this account much used as a top-dressing for crops and pastures. It must not be mixed with lime, nor applied to soil which has been recently limed, as the lime drives off the ammonia, which is dissipated in the air (the

same caution applies to fertilizers containing organic nitrogen). Dissolved in water at the rate of from ½ to 1 oz. per gallon, it is very beneficial to flowers and pot-plants, especially on clay soils. Nitrate of soda (Chile saltpetre) is imported from the nitre-deposits of Chile and Peru. Whereas importations to the continent of Europe and Great Britain attain enormous figures annually, only relatively small quantities reach Australia, as the high freights make it more expensive than sulphate of ammonia, and it does not appear to have higher manurial value. It contains about 16 per cent of nitrogen. Calcium cyanamide (nitrolim) is obtained in the fixation of nitrogen from the atmosphere by passing air over calcium carbide at the high temperature produced by an electric furnace. It has a lower nitrogen-content than sulphate of ammonia. Though used extensively in Europe and America, it is not yet produced for the market in Australia, and the high cost of oversea carriage makes it practically unprocurable otherwise. Calcium nitrate (nitrate of lime), which contains about 13 per cent of nitrogen, is the substance obtained when air is subjected to the discharge of the electric arc; at this high temperature the oxygen and nitrogen of the air unite to form oxides of nitrogen, which when absorbed by lime are put on the market as nitrate of lime. Like nitrolim, it is not produced in Australia and is costly to obtain from outside.

Phosphatic manures are more generally used in Australia; in most wheat-growing areas manuring is practically confined to the application of superphosphate. Phosphoric acid is applied to the soil in the form of phosphate of lime, and occurs naturally in rock-phosphate, bones and guano. Bone-dust is a phosphatic as well as a nitrogenous fertilizer, and only requires the addition of a potash salt to make it a complete manure. Rock-phosphates, which contain no nitrogen, constitute the principal source of superphosphate. They are brought to Australia in large quantities from the Pacific islands; considerable deposits have been found on the mainland and placed on the market, in the ground state or made into superphosphate. The phosphate of lime in rock-phosphate, bones and guano, is tri-calcic phosphate, insoluble in water; these substances are consequently very slow in their action—particularly mineral phosphate (phosphate rock)—and must be reduced to a fine powder before they are likely to act as plant-food. When converted by treatment with acid into superphosphate, they form a mono-calcic phosphate readily soluble in water and rapidly assimilated by the growing plant. True guano is the dung of fish-eating birds, deposited in enormous quantities on areas of Chile and Peru and on certain islands. Fresh guano contains both nitrogen and phosphoric acid; but in course of time the nitrogenous matter is dissipated by fermentation and leaching, and the older deposits are almost pure phosphate of lime, consolidated to a rock through pressure. The term is, however, commonly applied to other substances, e.g. bat-guano, the dung of bats and flying foxes, frequently found in extensive deposits in caves where these animals breed; and fish-guano, which is merely fish-scrap or refuse. Manufacturers also use it to denote an artificial mixture of one or more manurial substances; thus mixtures of sulphate of ammonia, superphosphate and sulphate of potash are often called guanos.

Superphosphate is by far the most widely used fertilizer in Australia. It is manufactured from rock-phosphate or bones ground finely and mixed with sulphuric acid; to the ground-up bones or rock enough acid is added to moisten it and the mixture, when thoroughly stirred, is stacked in heaps to dry. The acid converts the original tri-calcic phosphate (which is insoluble in water) into a mono-calcic water-soluble phosphate. Sulphate of lime is also formed by the reaction, so that, though essentially a phosphate manure, the mixture contains a considerable quantity of lime salts. The superphosphate usually sold contains about 17 or 18 per cent of water-soluble phosphoric acid, equivalent to 36 to 38 per cent of phosphate of lime. The great fertilizing value of superphosphate is due to the fact that, being in solution, the phosphate is very much more finely divided and distributed in the soil. As soon as superphosphate is in contact with the soil, it is believed to combine with the carbonate of lime and such iron and alumina as may be present, passing from the water-soluble condition into another form of phosphate of lime; this is insoluble in water, but soluble in the weak acids in the soil, and is known as 'citrate-soluble' or 'reverted' phosphoric acid.

Nitrate of soda, which is generally used by growers in Europe and America, is practically unused in the wheat-lands of Australia, its place being taken by superphosphates. The addition of nitrogenous and potash manures appears to have little or no effect on the wheat-yield either when used alone or in mixtures; on the other hand, the application of superphosphates (even in such small quantities as 30 to 40 lb. to the acre) produces a very marked influence on the yield. In comparatively moist and cool climates the wheat commences to grow at a time of year when nitrification is inactive, and when any nitrates that were present in the soil have been washed out, whereas the active nitrification-period is during the summer months, when the plant has already arrived at a certain stage of maturity. Nitrate of soda is therefore useful as supplying the nitrate necessary for early growth. In Australia nitrification is active and progressive during the early stages of the plant's growth, and no additional nitrogenous manure is required; but the soils are for the most part deficient in phosphoric acid, which promotes the development of the root-system and thus ensures for the young plant a vigorous start.

Basic slag or Thomas phosphate, another form of phosphoric acid, is occasionally procurable in the Australian market. It is used extensively in Europe and America, where it can be obtained at a low cost as a waste product in the manufacture of steel in the Thomas-Gilchrist process. It contains, in the form of phosphate of lime, the phosphorus that was originally in the pig-iron. This phosphate of lime, unlike any of those hitherto discussed, is a tetra-calcic phosphate, insoluble in water, but citrate-soluble like the bi-calcic or reverted phosphates already mentioned. It cannot be either imported or produced locally in competition with superphosphate; but it has the advantage of containing free lime, so that it is an alkaline fertilizer (whereas superphosphate is acid), and is consequently better adapted for sour soils and stiff clays.

The potash-salts used as fertilizers in Australia are sulphate of potash, potassium chloride (muriate of potash), and kainit—all in pre-war days imported from the potash-mines at Stassfurt, Germany, which practically held the monopoly of the world's supply of potash. Sulphate of potash was most in demand locally, as it is a concentrated form, containing about 52 per cent of potash, and is more generally applicable.

It is used by manure-manufacturers principally to supply the necessary potash for their 'complete' manures. Potassium chloride has a somewhat higher potash-content than the sulphate, but is less widely applicable; a few crops—potatoes and tobacco among the number—do not do so well when manured with chloride. During the war the source of supply was cut off and potash-salts were unobtainable, substitutes being found in substances rich in potash, such as wood-ashes, ground felspar, etc. Immediately after the war potash-mines in the neighbourhood of Mulhouse in Alsace were opened up by a French company to supply potassium chloride, which was for some time the only potash-salt available. At the present time both sulphate and chloride are on the market again. Kainit is a mixture consisting principally of chlorides and sulphates of potash and magnesia. It contains about 12 per cent of potash.

Attempts are being made to utilize local sources of potash supply, but no potash-mines have as yet been discovered in Australia, and other sources must be sought. Among the substances most likely to supply the demand are wood-ashes, potash-felspar, alunite, kelp or seaweed ash, wool-suint, wine-press residues, argol and tartar. Wood-ashes contain all the mineral elements of a complete fertilizer, and may be used for pastures, leguminous crops, fruit-trees and other crops. They consist chiefly of carbonates of lime and potash, together with phosphates of the same bases; the potash compounds are water-soluble and readily available. Nitrogen is absent, having been driven off in the burning process. The potash-content varies according to the nature and age of the original tree, and the part of it from which the ashes were obtained. The ash of young wood is particularly rich in potash; generally speaking, indeed, the ash of young and small wood is more valuable than that obtained from the trunks of old trees.

The manures which depend for their action on the presence of lime are carbonate of lime, burnt lime and sulphate of lime (gypsum). Carbonate of lime occurs in nature in rock-masses as limestone, chalk or coral, and is used, after pulverization, to sweeten sour soils or to enrich soils poor in lime. Burnt lime as a soil-ameliorant is superior to carbonate of lime, since it possesses the property of breaking up stiff clay soils and rendering them friable. It is usually applied at the rate of about ½ ton to ¾ ton per acre. The stone-lime, broken up into lumps, is placed in heaps on the field, where it slakes when exposed to moist air, and crumbles to a soft white powder that can be spread evenly over the surface and harrowed in very lightly. Under dry conditions it may be necessary to water the heaps to assist the slaking process.

Gypsum (sulphate of lime, land-plaster, copai), occurs, like carbonate of lime, in rock-masses. It is applied only to soils poor in lime, or to crops like legumes and grape-vines. It is not a soil-ameliorant, but has been successfully employed on land suffering from alkaline bore-water; for this purpose it may either be sown on the land in the powdered form, or placed in the irrigation channels, or—if the water is stored—in the tanks or reservoirs. So-called 'agricultural' lime, really screenings from the lime-kilns, consists of the smaller pieces and imperfectly burnt or over-burnt lime unsuitable for building. Other waste-products rich in lime are (*a*) lime from fellmongeries, where it is used to remove hair from the hides; it contains a considerable quantity of hair and organic matter, and is thus also a nitrogenous manure; (*b*) lime-residues from acetylene-generators, which are almost pure slaked lime and carbonate of lime, and can be used instead of carbonate of lime; (*c*) gas-lime, procurable from gas-works where lime is used during the purification of coal-gas; the spent product affords the farmer a cheap source of lime. Marine Fibre, the name applied to the fibrous portion of the leaf-sheath of *Posidonia australis*, a plant growing in shallow waters along the southern coast of Australia, especially in Spencer and St. Vincent gulfs. It appears to be endemic in Australia; a near relative, *Posidonia oceanica*, is limited to the Mediterranean and the European shores of the Atlantic Ocean. It is not a seaweed, but a submerged flowering plant of the family Zostereae.

Normally the plant grows in masses on the sea-bottom, dies, and disappears. But in comparatively sheltered localities—especially those in the north-eastern corners of the two South Australian gulfs, on which the prevailing south-east winds accumulate a good deal of drift-sand and similar matter—the fibrous residues of the rotted leaves and stems have accumulated in the drift (which seems to preserve them) and fresh colonies of *Posidonia* have grown on the bottom thus formed, until in some parts of Spencer Gulf the deposits are seven feet thick. Every cubic yard of deposit yields fibre that, when air-dried, weighs about 6 lb., its constituent filaments being sometimes 9 in. long and about as coarse as those of jute. Their mean breaking strain is 20.15 kilograms per sq. millimetre of cross section, slightly less than that of jute. They are brittle under a sudden strain, though elastic if the strain is steady and direct.

The fibre was first brought into prominence in 1902, when S. H. Manners applied for permission to work the deposits near Tickera, a little north of Wallaroo on Spencer Gulf. For some time, indeed, it was known to commerce as Tickera fibre. In 1905 Manners took to England samples of the cleaned fibre, and Marine Fibre and Yarns, Ltd., was formed to exploit the deposits; later on, another company was floated in Sydney, and a third in Holland, and many areas were worked by private speculators. In June 1911 375 sq. miles of deposits were held under lease from the South Australian government; but great difficulty was experienced in separating the fibre from the sand in which it was embedded, and the parent company ceased operations at the end of 1911 after having produced only 25 tons of marketable fibre. It was then that the Sydney company—Australian Marine Fibres, Ltd.—solved the problem of separation, only to be confronted with the no less difficult one of drying the product. However, it and its successor Posidonia, Ltd., in six years managed to obtain about 220 tons from deposits near Port Broughton. The Dutch company, which began operations in 1913, using a more costly process which involved the use of fresh water for cleaning the fibre, obtained from deposits in the Port Piric region about 120 tons in four years.

Posidonia fibre has been scientifically investigated by the Imperial Institute in 1909 and 1911,

by the South Australian department of chemistry in 1917, and by the Commonwealth Institute of Science and Industry in 1919. Its possible commercial uses, suggested by these authorities, are (*a*) as a diluent of wool in the manufacture of low-grade fabrics; (*b*) for manufacture into guano-bags, horse-blankets, etc., which have to stand no great strain but are much exposed to the weather or to chemical action; (*c*) as an insulating agent for heat; (*d*) as a substitute for jute in the backings of oilcloth and rugs, and for horsehair or kapok in bedding and upholstery; and (*e*) for papermaking. Up to the present time its principal use has been as an insulating agent.

See *Bulletin No. 14* of the Institute of Science and Industry (Melbourne, 1919), and *Bulletin No. 4* of the South Australian department of chemistry (Adelaide, 1916).

Marsden, SAMUEL (1764-1838), born at Farsley near Leeds in Yorkshire on 28 July 1764 and educated at the free grammar school of Hull, was apprenticed to blacksmithing at Horsforth, but by his piety and ability attracted the attention of the Elland Society (of which William Wilberforce was a prominent member), and in 1790 was sent by them to Magdalene College, Cambridge, to be trained for the ministry. Wilberforce and his associates had been partly responsible for sending the first chaplain, Richard Johnson (q.v.) to New South Wales, and when he asked for assistance they recommended Marsden, who was appointed assistant chaplain for the colony on 1 January 1793. He was ordained priest, sailed in the storeship *William* on 28 August 1793, and reached Sydney on 10 March 1794. On arrival he settled in Parramatta, holding services until 1796 in a carpenter's shop fitted up for the purpose; he then erected a 'wooden temple' on the south-eastern corner of George- and Marsden-street, and in 1797 the foundation-stone of St. John's church was laid (see CHURCH OF ENGLAND). On 15 December 1794 Marsden took over the duties of the military chaplain, James Bain, and in 1800, when Johnson went on leave, was left in charge of religious functions at Sydney, Parramatta and the neighbouring districts. He also took a lively interest in the Pacific missions of the London Missionary Society. He was a magistrate and superintendent of public works at Parramatta and Toongabbie, and took an active part in the establishment and control of orphan schools. But these multifarious official duties did not absorb all his phenomenal energy; he was commended by Governor King as 'the best practical farmer in the colony,' and was a keen student of sheep-breeding and wool-production (see SHEEP). In 1802 Péron, one of Bougainville's officers, spoke in glowing terms of his model farm, Mamre, near St. Mary's, and by 1806 he had acquired by grant or purchase 2908 acres carrying 1416 sheep. In 1807 he visited England, and while there induced William Cowper and Robert Cartwright to offer themselves as assistant chaplains; he also arranged with the Church Missionary Society to organize missionary enterprise in New Zealand. He was in England when news arrived of the deposition of Bligh, and at once championed the cause of the ex-governor, thus drawing down upon himself John Macarthur's wrath.

Marsden returned to the colony early in 1810 and, though senior chaplain, was permitted to remain at Parramatta, an assistant being stationed at Sydney. From the outset he opposed Macquarie's emancipist policy, and this remained a permanent cause of misunderstanding between them; for more than seven years, however, their relations remained outwardly cordial. Macquarie, to check the growth of sectarianism, ordered Marsden to desist from certain 'methodistical' practices introduced by him into the church services, but gave him constant support in his missionary enterprises. When in 1814 Marsden proceeded to New Zealand to establish a mission in connection with the Church Missionary Society, Macquarie gave the undertaking a semi-official status. Marsden, however, bought a vessel at his own expense to further the enterprise, and used it to promote trade in island products. He does not seem to have profited materially from his trading connections; but he had strong secular leanings, and was (as Bigge suggested) 'less sensible than he ought to have been to the impropriety of combining operations of a mercantile nature with the duties of his profession.' Moreover, though zealous for the New Zealand mission, he showed no interest in Macquarie's efforts to improve the conditions of the Australian aborigines. On 4 January 1817, J. T. Campbell, the governor's secretary, published anonymously in the *Sydney Gazette* (of which he was censor) a bitter attack on Marsden's missionary activities. On the advice of the judge-advocate (who hoped thereby to facilitate a private settlement of the quarrel) Macquarie publicly dissociated the government from the views expressed in the letter, for which he was in no way responsible; but Marsden insisted on prosecuting Campbell, and on 1 December 1817 was awarded heavy damages for libel. On the same day Macquarie tendered his resignation to Lord Bathurst. Early in the year he had received from the colonial office a letter from a colonist containing serious charges against his administration, and alleging ill-treatment of prisoners; this letter he believed to have been written by Marsden—it was in fact the work of Nicholas Bayley, one of Marsden's friends—and he attributed the unfriendly tone of recent official communications to Marsden's secret machinations. In denying the charges, he pointed out that the punishments inflicted by Marsden's authority were much more severe than those of any other magistrate in the colony. (After a long controversy Marsden published in 1826 *An Answer to certain Calumnies in the late Governor Macquarie's Pamphlet and the Third Edition of Mr. Wentworth's Account of Australasia.*) Long opposed by Marsden on the emancipist issue, and embittered by recent developments, Macquarie now refused to recognize the chaplain as a private acquaintance, and in 1818 dismissed him from the magistracy in a very humiliating manner. Marsden thereupon applied for leave to visit England on the ground that he wished to secure the services of additional chaplains, and was refused because Macquarie believed his real motive to be an attack on the administration. In 1819 Marsden again visited the New Zealand mission, and thereafter Bigge's influence had a moderating effect on both governor and chaplain.

Brisbane had no high opinion of Marsden, and soon complained of his 'daily neglect of the spiritual concerns of his Parish for the sake of attending to his own multitudinous temporal affairs.' In 1822 he removed from the commission of peace the names of Marsden (who had been reappointed on Brisbane's arrival) and four other magistrates for refusing to sit with

Dr. Douglass, superintendent of the female factory and a close friend of the governor. In the following year Marsden was fined by the Parramatta bench (on which Douglass was sitting) for a minor offence, the fine being ultimately secured by distress warrant; Marsden thereupon sued the magistrates in the supreme court, which decided that they had acted without authority (though not maliciously) and awarded him the amount of the fine and costs. Marsden appealed to the British home secretary; he passed the complaint on to the colonial office, which ordered Governor Brisbane, Chief Justice Forbes, and Archdeacon Scott to inquire into several allegations against Douglass. Their report, issued in August 1825, cleared Douglass and showed that Marsden's statement to the home office was inaccurate; to straighten out a few irregularities in procedure, to which Marsden himself had been a party in past years, a bill of indemnity was passed to protect magistrates from further proceedings. Earl Bathurst thereupon instructed Brisbane to censure Marsden in private (a public reprimand would, he considered, prejudicially affect the position of the clergy) and 'intimate to him my expectation that he will for the future repress the vehemence of temper, which has too frequently marked his conduct of late, and which is as little suited to his Age, as it is to the profession to which he belongs.' Marsden in 1828 published a *Statement, including a Correspondence between the Commissioners of the Court of Inquiry and the Revd. Samuel Marsden,* in which he imputed motives of partiality and injustice to the committee; this called forth a refutation, in a letter to the colonial office, by Chief Justice Forbes; and with that the unseemly controversy was brought to a close.

Marsden thenceforth devoted his failing energies to his ministerial work, now under the supervision of Archdeacon Scott. The New Zealand mission, the most noteworthy enterprise of his life, developed rapidly under his guidance; altogether he paid it seven visits, the last in 1837. His relations with Brisbane's successors were friendly, and several recommendations were made by them to the colonial office in favour of a suitable provision for his old age. He died at Windsor on 12 May 1838, leaving behind him a reputation for somewhat unbalanced and often misdirected zeal in his New South Wales career, but for excellent good sense and apostolic enthusiasm displayed in all his work for New Zealand.

Marsupials, an order of mammals of limited geographical distribution, most richly developed in the Australian region. The name is derived from the marsupium or pouch present in the females of most marsupials, which serves for the transport and protection of the young; such a pouch is not developed in any other mammals except, in a modified form, in the monotreme *Tachyglossus* (echidna, q.v.). Among other distinguishing features, one of the most striking is the nature of the relations between the female parent and her offspring. Like the higher mammals, the marsupials are viviparous; but in the higher mammals special provision is made for the nourishment of the young animal before birth, a close relationship being established by means of the placenta between the blood-systems of the mother and of the young or foetus. Most marsupials have no placenta: only one of them —the bandicoot—has a placenta of the same nature as that of the higher mammals, and in its case the structure is much simplified. In consequence of this imperfect provision for the nutrition of the foetus, the young of the marsupial is born comparatively incomplete, and remains a 'mammary foetus,' helplessly hanging to one of the teats within the pouch for a considerable time before it is able to make any effort even to draw the milk.

The milk-glands, or mammary glands, of the marsupials are essentially of the same nature as those of higher mammals; the chief peculiarity

'Mammary foetus' of kangaroo lying inside pouch.

about them is that a muscle which extends over them is under the control of the animal; when it is contracted the milk is squeezed into the mouth of the helpless 'mammary foetus.' By a special arrangement of the infant's air-passages it is possible to draw in air through the nostrils and down the windpipe to the lungs without interfering with the passage of milk to the gullet. The smallness and helplessness of the newly-born marsupial, together with the fact that bleeding follows forcible removal from the teat, have led to the wide acceptance among bushmen of the remarkable doctrine that the young animal grows on the teat much as an apple grows on a tree. The birth of the marsupial is seldom actually observed; but the conveying of the young by the mother's lips to the pouch, and the adjustment of the mouth over the end of the teat, have been described by various observers of repute. On the other hand, others have described from personal observation the struggles of the newly-born young of the kangaroo over the mother's fur by movements of the fore-limbs—which at this stage are better developed than the hind-limbs—until they reached the pouch and attached themselves to the teat. However this transference may take place (and there is doubtless variation of method in different cases), it does not affect the question of the actual mode of birth, which does not fundamentally differ from that in other mammals. The bleeding which takes place when the 'mammary foetus' is forcibly removed is due to the fact that the extremity of the teat becomes enlarged after it has been received into the mouth of the young animal, and the

force necessary to pull the foetus off ruptures the skin of the teat.

Australia is the headquarters of the marsupial order, and the greater part of her mammalian fauna belongs to that group. Owing to the geographical isolation of the continent through long ages—during which the higher mammals were being evolved and reaching predominance in other parts of the world—the primitive monotreme and marsupial fauna remained undisturbed, and the marsupials underwent a variety of modifications adapting them to a great variety of modes of life; consequently families of Australian marsupials show a remarkable correspondence in structure and mode of life with families of higher mammals in other regions. Thus kangaroos and wallabies, grass-eating mammals with the limbs adapted to swift movement on the ground, are the marsupial equivalents of deer, antelopes, buffaloes, and other ruminants; the tree-inhabiting 'opossums' (phalangers) and native bears (koalas) are comparable to the tree-inhabiting lemurs and monkeys, as are 'flying opossums' to flying squirrels. The bandicoots on the one hand and the wombats on the other represent other families of rodents. The carnivorous native cats, Tasmanian devil, and Tasmanian wolf closely parallel some groups of the true Carnivora; moles of the order Insectivora find a marsupial analogue in the marsupial mole (see MOLE, MARSUPIAL) of the Australian desert.

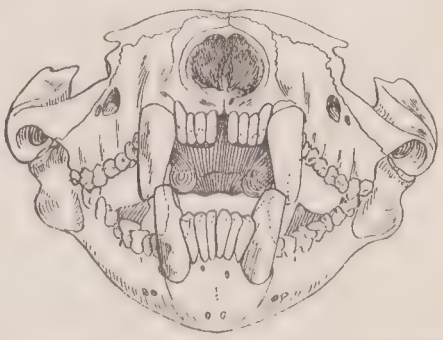
Marsupials are conveniently divisible into two main sections or sub-orders—Diprotodontia, with two front teeth, and Polyprotodontia, with many front teeth. In Diprotodontia it is only in the lower jaw that the number of well-developed front (incisor) teeth is actually reduced to two: there are nearly always more than two in the upper jaw, but of these the two central teeth

Diprotodont:—front view of skull of Koala (*Phascolarctus cinereus*).

are specially developed, and correspond to the two prominent front teeth of the lower jaw against which they work. In Polyprotodontia there are usually four incisor teeth on either side in the upper jaw, and three in the lower.

Besides the difference in the teeth, diprotodonts differ from polyprotodonts in the universal occurrence in the former—and absence in the latter (excepting the bandicoots)—of syndactylism, that is to say, the union of the second and third toes (usually small and slender) by a web of skin.

Diprotodonts comprise kangaroos and wallabies, wombats, Australian opossums (phalangers), and the koala (native bear). Polyprotodonts include among others native cats, bandicoots, the marsupial mole, and the true American opossums (Didelphyidae). The last-named family includes all marsupials now found living outside the Australian region, with the exception of one small rat-like form, *Caenolestes*, which



Polyprotodont:—front view of skull of Tasmanian Devil (*Sarcophilus harrisi*).

occurs in Bolivia and Ecuador. *Caenolestes* cannot be definitely assigned either to the diprotodont or to the polyprotodont sections; its nearest relatives appear to be certain extinct families, the remains of which occur in beds regarded as of Tertiary (Miocene) age in South America. Virtually all the diprotodonts now living are inhabitants of the Australian region.

The difference in teeth between Diprotodontia and Polyprotodontia is connected with radical differences in habits and mode of life, more particularly in the nature of the food. In the diprotodonts the food consists of herbage, leaves of trees, fruit, and roots; and the grinding-teeth are adapted to this class of food. The polyprotodonts, on the other hand, are carnivorous or insectivorous, the modifications which their teeth undergo resembling remarkably those that characterize the true Carnivora (e.g. cats and dogs) or the true Insectivora (e.g. moles and hedgehogs). All marsupial teeth, however, are uniform at least in one respect, in which fossil forms, so far as is known, agree with living. Most mammals have two sets of teeth, of which the first-formed set (the 'milk' or deciduous series) sooner or later is lost and replaced by the teeth of the second or permanent set. Of the teeth of the permanent set a small number—one to four on each side of each jaw—do not actually replace members of the 'milk' series, behind the last of which they are developed. They are the molar teeth of the permanent series, and the teeth immediately in front of them, between them and the usually prominent eye-teeth or canines, are called pre-molars. In marsupials there is never more than one complete set of teeth, and it is doubtful whether this corresponds to a 'milk' set which persists throughout life, or to a permanent set which has no milk-teeth preceding it. One tooth alone of the whole series undergoes replacement; this is the tooth corresponding either to the third or to the fourth pre-molar.

Though marsupials are more abundant and more varied in Australia than in any other part of the world, yet, as already indicated, the order is not by any means confined to this strictly circumscribed region. An entire family (that of

the true or American opossums, comprising about 24 species) is confined to America; the only living representative (*Caenolestes*) of an entirely distinct group is also an inhabitant of the same continent. But in addition the Australian marsupial fauna has overflowed the boundaries of the continent. Tasmania, isolated from Australia proper only in comparatively recent ages, practically forms a part of the mainland in a zoological sense, though retaining certain forms (such as the Tasmanian devil and the Tasmanian wolf) that have vanished from the mainland. New Guinea, likewise recently separated, contains over 60 species of marsupials (wallabies, tree-kangaroos, cuscus phalangers, bandicoots, and native cats). A wallaby occurs in the Aru Islands; a *Phascogale* and a wallaby in the New Britain group; a cuscus in Amboina, the Solomons, Timor, and some of the smaller islands, and another cuscus in Celebes.

Martens, CONRAD (1801-1878), born in the parish of Crutched Friars near the Tower in London, was the son of a Hamburg merchant who permitted his three sons to take up the perilous career of art. Conrad chose Copley Fielding, the most fashionable teacher of the day, for his master, and was well grounded in the practice of water-colour and drawing with the point. In 1832 he left England, probably sailing for South America in H.M.S. *Hyacinth*; he was certainly in Monte Video when the *Beagle* arrived there with Charles Darwin on board. Martens replaced Augustus Earle (invalided home) as official topographer, and remained with the expedition for two years. He left the *Beagle* at Valparaiso in July 1834, sailed for Tahiti in a Yankee schooner on 3 December, and for a couple of months made sketches on the island. He left for Sydney on 4 March 1835, and after staying at the Bay of Islands in New Zealand for five days in April, made his first sketch of Port Jackson Heads on the 17th of that month.

Martens lodged in Cumberland-street, overlooking Sydney Cove, and set up as a drawing-master. He had also a studio in Mort's buildings, which he retained till as late as 1856. In 1844 he built for himself a cottage at St. Leonard's on the northern side of the harbour. Most of his income was derived from painting or drawing big country-houses for their owners, and from the sale of views of Sydney harbour —including a notable hand-coloured lithograph of Sydney from the North Shore for which he found a ready market. His leanest year brought him in £50, his fattest £350; in 1863, when too old to continue painting, he was made assistant parliamentary librarian. He died of angina pectoris on 21 August 1878.

A man of good taste and some reading, Martens was the first painter of note to settle in Australia and win respect for his art. As a sketcher he is still pre-eminent, for he was extraordinarily skilful in suggesting and defining landscape form. His innumerable drawings form a topographical history of his times. He painted a little in oil, but never mastered that medium as he did water-colour. His compositions are in the classic and Turnerian tradition, yet he had an eye for the character of a landscape. He painted invariably from notes and studies, and made sincere efforts to convey Australian forms, but his method was not favourable to realism. Always a graceful painter, his fame rests upon his pencil sketches and views of Sydney harbour, of whose beauty he was the first exponent. See ART.

See *Conrad Martens: the Man and his Art* (Sydney, 1920), which contains reproductions (mostly in colour) of more than 60 of his pictures and sketches, prefaced by a biography and a critical estimate of his work. L.L.

Martin, CHARLES JAMES, born in London in 1866 and educated at King's College, London, and the university of Leipzig, was in 1887 made demonstrator in biology at King's College and in 1891 demonstrator in physiology in the university of Sydney. Here for six years he made important researches into the embryology of the *Ornithorhynchus anatinus*, collaborating with J. T. Wilson (q.v.), and the effects of snake-poison on human blood. Transferred to Melbourne in 1897 to act as locum tenens for the professor of physiology there, he was in 1901 given the professorship, but soon afterwards left Australia to conduct for the British government investigations into anti-typhoid inoculation (chairman of war office committee, 1904-7) and the plague in India (member of joint advisory committee, 1905-13). In 1906 he was made director of the Lister institute of preventive medicine, which position he still (1926) holds. During the war he served with the A.I.F. as lieutenant-colonel in the A.A.M.C. on the Gallipoli Peninsula and in Egypt, Palestine and France. He is also professor of experimental pathology in the university of London, F.R.S. (1901), fellow of King's College, and D.Sc. of London and Melbourne, and holds honorary degrees of several other universities. (C.M.G., 1919.)

Martin, SIR JAMES (1820-1886), born at Midleton in county Cork, Ireland, on 14 May 1820, was brought by his parents to New South Wales in 1821, and educated at the Sydney Academy and Sydney College under W. T. Cape (q.v.). On leaving school he joined the staff of the *Australian*, for which he reported the proceedings of the legislative council, gaining thereby detailed information of parliamentary practice. In 1838 he published a slight volume of essays, *An Australian Sketch Book*. Two years later he was articled to G. R. Nichols (a prominent lawyer who had a proprietary interest in the *Australian*), and in 1845 was admitted a solicitor. When the *Atlas*, the squatter's organ, was established in 1844, he contributed to it fiery articles denouncing Governor Gipps, and shortly afterwards became editor—a position he held for about two years. In 1848 he was elected to the legislative council for Cook and Westmoreland, but was unseated on petition, being without the requisite property qualification; in 1849 he was returned unopposed, and retained his seat until the dissolution of the council in 1856. In August 1856, under responsible government, he became attorney-general in the Cowper ministry; as he was still only a solicitor the bar took umbrage at his appoint-

ment, and his political opponents carried a vote of censure upon the government. Before Cowper returned to power in 1857 Martin was called to the bar (Q.C., 1857), and his reappointment as attorney-general was unopposed, but he resigned in the following year. In 1863 he became premier and attorney-general; in 1864 the country rejected his proposals for a protective tariff, and he was in opposition until 1866, when he again formed a ministry, having induced Henry Parkes (q.v.), who opposed his fiscal policy, to become colonial secretary. Martin supported the education reforms fathered by Parkes, and was himself responsible for the industrial schools act and for the establishment of juvenile reformatories. His ministry was responsible for the Duke of Edinburgh's reception in 1867 and for the measures taken to frustrate any conspiracy against the Crown after O'Farrell's attack on the Duke at Clontarf. In October 1868 he resigned, but from December 1870 to May 1872 was again premier and attorney-general with John Robertson (q.v.), an erstwhile opponent, as colonial secretary. In November 1873 he was appointed chief justice of New South Wales with the unanimous approval of the bench and bar. From 1858 to 1878 he was a member of the senate of the university of Sydney. He died on 4 November 1886. (K.C.B., 1869.)

Martins. See SWALLOWS AND MARTINS.

Masson, SIR DAVID ORME, only son of Professor David Masson the late historiographer royal for Scotland, was born in London on 13 January 1858, educated at the Edinburgh Academy and the university of Edinburgh (M.A., 1878; B.Sc., 1880; D.Sc., 1884; hon. LL.D., 1924), and studied at Gottingen. In 1880-1 he lectured at University College, Bristol, as assistant to Professor William Ramsay, in 1882-5 held a research fellowship at Edinburgh, and in 1886 was appointed to the chair of chemistry at the university of Melbourne. This chair he held until 1924, when he was made professor emeritus. In 1912-16 he was a member of the council of the university and president of the professorial board.

In 1903 his chemical researches brought him a fellowship of the Royal Society of London. These researches extend over a wide range of subjects, the most important being those dealing with fundamental aspects of the ionic dissociation theory (particularly transport numbers) and the kineties of complex chemical reactions —such as that between hydrogen peroxide and potassium cyanide, and the hydrolytic decompositions of metallic cyanates and persulphuric acid and its salts.

Outside his strictly professorial work he has done much to advance public interest in scientific enterprises. From 1890 onwards he fostered the Australasian Association for the Advancement of Science, of which he was president in 1911-13; he gave valuable help to Mawson's Antarctic expedition of 1911-13; during the war he was deputy-chairman of the Commonwealth advisory council of the institute of science and industry (q.v.); in 1917 he led the movement to found the Australian Chemical Institute, and since 1922 has been president of the Australian national research council, of which he was an original member. Among other public services may be reckoned his active membership of a royal commission on the sanitation of Melbourne (1890), of the Victorian board of health, and of a board appointed by the Commonwealth to report on a proposed local issue of silver coinage. Matra, JAMES MARIO, is first heard of as a member of the *Endeavour's* crew under Cook; he was entered in the ship's books as 'Jas. Magoa (A.B. to 27 May 1771, then mid.).' In Cook's journal he figures as 'Magra,' and for some reason this was the spelling adopted by himself up to March 1775, and by his brother Perkins as late as 1795. From 1777 onwards, however, James persistently used the form 'Matra,' signing himself in the form given at the head of this article. In modern histories the variant 'Maria' is common, and 'Jean' also occurs. The Matras were a leading family of Corsica, but some of them quarrelled with Pasquale Paoli and even fought against him on the side of the Genoese invaders of the island; in consequence, the family was driven from its home and settled in New York, where during the Revolution it remained loyal to England. James was born in New York, and educated in England. During his term of service aboard the *Endeavour* he struck up a friendship with Banks that lasted the rest of their lives. In 1772 he was made British consul at Teneriffe; in 1777 he visited New York to recover what he might of the family property; in 1778 he became secretary to the British embassy at Constantinople. Five years later he appeared in London. What had happened in the interim we do not know; but he told Banks that 'for many months past I have been obliged to lead the life of a solitary fugitive . . . secluded as I was from Society.' From other sources we know that he was just then pressing his claims as a ruined American 'loyalist' and asking for a consulate somewhere in Spain. At the moment, as it happened, people in London were discussing the possibility of making new settlements in the South Seas; Banks had devised one plan for settling New South Wales, and Sir George Young another; there were also vague ideas regarding Madagascar and Norfolk Island. On 28 July 1783 Matra sent Banks a letter from which quotation is made above. The friends discussed plans together, and on 23 August Matra addressed to the British government—then the Fox-North coalition—'A Proposal for Establishing a Settlement in New South Wales,' intended 'to atone for the loss of our American colonies.' He proposed to use American loyalists like himself as settlers, with two companies of marines and 20 'artificers, potters, and gardeners' as pioneers, and women from New Caledonia or Tahiti as pioneers' wives; stock could be procured from the Cape or the Moluccas; and the settlement could be made in peace-time a centre for trade with eastern Asia and in war-time a base of attack on the Dutch colonies of Malaysia or the Spanish colonies of South America. He quoted Banks as strongly in favour of his scheme, and in a sort of foot-note approved of a suggestion of Lord Sydney to send out convicts as colonists, but only on condition that they should be given land to cultivate immediately on arrival and never be 'reproached' for their former crimes.

Matra's proposals were thus not original. A draft of an anonymous scheme almost identical with his (and much more carefully argued) is in the British home office, and Sir G. Young (q.v.) had a plan of his own, although he readily supported Matra's. But the Proposal of August

1783 was the first publicly made, and attracted great attention, especially among the loyalists for whose benefit it was made; for instance, James de Lancey, who had been by far the greatest landlord in southern New York State, constituted himself an agent for procuring colonists among the loyalist refugees in Nova Scotia, and was exceedingly disappointed when the scheme fell through. For it did fall through. Lord Sydney, who after the collapse of the coalition in 1783 had charge of colonial affairs (such as they were), took no interest in loyalists; all he wanted was to relieve British gaols and hulks of their accumulation of prisoners sentenced to transportation, and his scheme was the one finally adopted. As for Matra, at Banks's urgent request he was made consul-general at Tangier in Morocco in 1786, and died at his post on 29 March 1806.

In many discussions of Matra's life and importance it has been stated that there is no direct evidence of the identity of Cook's 'Magra' with the Matra of the Proposal. It happens, however, that after his last appointment (to Tangier) Nepean, secretary to the admiralty, sent Pitt, his prime minister, a note on the new consul which gives the required identification; Matra, he says, 'is a native of New York, but was educated in England, and has always been employed on the King's service. He accompanied Sir Joseph Banks in his voyage with Captain Cook. . . .' It looks as if Pitt has been told that Matra came from New York, and had doubted his loyalty therefor. A list of the *Endeavour's* officers in the 1784 (folio) edition of Cook's *Voyages* also explicitly identifies Magra and Matra. Another interesting point about this man of mystery is his age and status when in the *Endeavour*. Cook in 1770 calls him a midshipman, whereas the admiralty list leaves him an A.B. up to May 1771, and he himself in 1790 claims to have had 30 years' service, so that he must have served for at least ten years before becoming a midshipman.

17. *Delabrea Michieana*.

Mawson, SIR DOUGLAS, born at Bradford in Yorkshire on 5 May 1882, was brought by his family to Sydney while still a child, and educated at the Fort-street model school and the university of Sydney (B.E., Mining, 1901; B.Sc., 1904; D.Sc., Adelaide, 1909). In 1902 he was appointed demonstrator in chemistry at the university of Sydney, in 1903 carried out geological investigations in the New Hebrides, and in 1905 became lecturer in mineralogy and petrology at the university of Adelaide. He accompanied the Shackleton expedition of 1907-9 to the Antarctic (see ANTARCTICA) and with Edgeworth David (q.v.) succeeded in locating the magnetic pole. On his return to Adelaide he proposed an Australasian expedition to explore the unknown portions of the Australian antarctic quadrant, especially at the western end; he was supported by the Australasian Association for the Advancement of Science, and early in 1911 proceeded to England to make arrangements for the voyage. The *Aurora* (of the Newfoundland sealing-fleet) was refitted under the supervision of John Davis, who was to be her master, and a number of Greenland sledging-dogs were purchased. Mawson returned to Australia in July; at the end of November the party joined the *Aurora* at Hobart, and on 2 December set out for the south. The history of the expedition is narrated under ANTARCTICA. On 26 February 1914 Mawson and the rescue party returned direct to Adelaide. In 1915 he published *The Home of the Blizzard*, and was awarded the founder's medal of the Royal Geographical Society. He was then assigned to special war-work with commissions as captain (1916-18) and major (1918-19), and in 1920 was appointed professor of geology and mineralogy at Adelaide. In 1923 he was made a fellow of the Royal Society. (Kt. Bach., 1914; O.B.E., 1923.)

May, PHILIP WILLIAM (1864-1903), known as Phil May, was born at New Wortley near Leeds, England, on 22 April 1864, the seventh child of Philip William May. His paternal grandfather, Charles May, squire of Whittington near Chesterfield, and Master of the local Beagles, was a gifted amateur, who made clever

Drawn by Edith A. King.

FLOWERS OF EASTERN AUSTRALIA

(A Key to this Plate is printed with the article on Waratah)

caricatures of village worthies in water-colours. His maternal grandfather, Eugene Macarthy, a graduate of the university of Dublin, became an actor of some distinction, and was for a time manager of Drury Lane Theatre; a daughter (the sister of Phil May's mother) successfully followed her father's bent. Charles May of Whittington was a friend of George Stephenson, the famous locomotive engineer, to whom he apprenticed his son Philip. Philip May afterwards established a brass-foundry in London, but failed in business and died, leaving his family in distress. His widow returned to Leeds, where her son Phil spasmodically attended St. George's board school until his 12th year. He then worked as an errand-boy, first for a solicitor, then for an architect. For a time he earned half-a-crown a week, dusting pianos, but soon transferred his talents to the office of a timekeeper at a foundry. Through the good offices of a boyish friend, the son of a scene-painter, he obtained more congenial employment at the Grand Theatre, Leeds, where in his time he played many parts, mixing paints, helping to design costumes, and sometimes taking minor rôles. 'You should have seen me,' he afterwards said, 'play servants and guests and hind legs of donkeys.' A by-product of his activities at this time was a series of commissions to draw the portraits of players, for which he commanded as much as 5s. He also drew posters for the front of the theatre. 'I never had a drawing lesson in my life,' he once said, 'but I can't remember a time when I didn't draw.' In 1878, at 14, he was contributing drawings to a short-lived local paper, *Yorkshire Gossip*. He then joined a touring company, playing small parts and sketching posters at a salary of 12s. a week. Leaving this company after a couple of years, he continued his fortuitous career at Leeds till 1883, when at the age of 19, with a capital of £1, he sought his fortune in London.

During the next two years he contrived a precarious existence, seldom far above starvation level. To this period of his career many apocryphal anecdotes have been attached, but there is little doubt that, apart from an occasional guinea from such modest periodicals as *The Penny Illustrated* and *The Pictorial World*, and two guineas which Lionel Brough paid him for a caricature of the three famous actors, Irving, Bancroft and Toole, he received no encouragement to pursue his vocation. He returned to Leeds, ill, starving, beaten by London. Then he suddenly received from the editor of *St. Stephen's Review* a commission for a cover-design and certain illustrations for the Christmas number. His complete success in this work, however, did not bring him permanent employment until the spring of 1885, when William Allison, editor of *St. Stephen's Review*, gave him a position on the staff. So at the age of 21, after much tribulation, Phil May began to achieve his ambition. He was earning from £8 to £10 a week with *St. Stephen's* when, towards the end of 1885, after some negotiation with W. H. Traill, managing director of the Sydney *Bulletin*, he entered into a contract with that paper for three years at £1000 a year, and arrived in Sydney at the beginning of 1886 at the very outset of his remarkable career. Various reasons have been given to account for his coming to Australia at the time when he had begun to achieve success in London, which he loved with all his Bohemian heart. It can confidently be said that the primary reason was connected with his marriage, which took place not long after his arrival in Sydney. May remained in Australia nearly three years, leaving in October 1888, and contributed altogether to the *Bulletin* nearly 900 drawings, the last of which appeared in 1894. In 1892 he was back in London after a sojourn in Paris, where he had nominally been studying painting, for which he had little aptitude. His brilliant illustrations to *The Parson and the Painter*, which had appeared in book form in 1891, revealed his mature powers as a draughtsman and helped to establish his popularity. From this time onwards his output was great. *Phil May's Winter Annual* was published from 1892 until 1903, the year of his death. He did much excellent work for the *Daily Graphic* and various other illustrated papers. In 1895 he published *Phil May's Sketch Book*, and next year *Gutter-snipes*. In 1896 he joined the staff of *Punch*, and almost until his untimely death in 1903 continued to publish in that paper and elsewhere those brilliant topical sketches which have gained him so much fame and produced so many imitators, though scarcely a rival. He died at St. John's Wood, London, on 5 August 1903, and was buried at Kensal Green.

Phil May was a great draughtsman in his own right; he received no teaching; he belonged to no school—though he created one—and his style developed only in the sense that practice enabled him ever more fully to express his own individuality; in other words, improvement was due to increasing penetration of vision and increasing skill in the selection of significant lines (which were the only ones he finally left in a drawing), and not to the conscious influence of other contemporary styles. 'Sambourne's work was the only work,' he once said, 'that ever influenced me—in the sense that I saw how much could be expressed in a line; but I never set about copying anyone.' Yet, when he came to Sydney, May's style was quite immature, and the influence of Linley Sambourne is to be found chiefly in a certain statuesque stiffness, due perhaps to the complacency with which that draughtsman had accepted the limitations of the wood-engraver. It has been too often assumed from the shortness of his stay in Australia that it was a mere interlude in his career and had a negligible influence on his style. But when he returned to England in his 25th year, he revealed a mature and vivid style, marked by the strength, certainty, and rigorous selection of his almost living line. This was no mere accident though it has sometimes been attributed to a curiously accidental cause—the inadequacy of the printing-machines of the Sydney *Bulletin*. His remarkable development in Australia was rather due to certain other facts. (*a*) During these years he freed himself from the influence of such men as the *Punch* group—Du Maurier, Tenniel, and Sambourne—and of Baxter, the creator of Ally Sloper. (Baxter, by the way, had been invited to join the *Bulletin* staff before May.) This liberation was assisted by the advice of two very able draughtsmen on the *Bulletin* staff at that time, Livingston Hopkins and William Macleod. (*b*) May was engaged in Australia chiefly upon political cartoons, work which he seldom attempted later in England, and for which he had no liking; but the discipline—and Phil May constantly needed some discipline—greatly increased his insight into the essentials of character and assisted their brusque and emphatic presentation in a simple language of line easily understood of the people. More-

over, he collected many types in Australia which he continued to employ long after his return to England. His cover-design for the Christmas number of the *Pall Mall Budget* in 1894 is a genial presentation of Sir Henry Parkes as Santa Claus.

Soon after his return to London Phil May was deservedly acclaimed as the greatest master of his chosen medium. Whistler declared that he was the only black-and-white artist of genius in England, and, when asked what was the future of that art, he answered again—'Phil May.' The multitude of May's subsequent imitators proves the shrewdness of this dictum. Among his contemporaries the only artist in the same style who may aptly be compared with him is the great French illustrator, Steinlen, who has so brilliantly portrayed the daily life and amusements of the Parisian *ouvrier* and *boulevardier*. In the history of English black-and-white Phil May has been placed with Hogarth and Keene as the third of a great trio. Although the perilous carelessness of his life often seems to be imported into his art, the appearance is delusive. Few draughtsmen were more painstaking. Beautiful and meticulously drawn sketches were copied by means of tracing-paper on to Bristol-board, line after line being sacrificed in the process, until only the significant, structural lines remained, to be rendered finally in that decisive and vivacious manner for which he is so famous—the art which conceals art.

In his private life Phil May was the victim of his own geniality, but few men have been so well loved by their associates. He was, as the memorial tablet erected to him at Leeds in 1910 records, 'a great black and white artist' and 'a fellow of infinite jest.'

Phil May's books, other than those named above, are: *'Graphic' Pictures* (1897); *A.B.C. 52 Designs forming two Humorous Alphabets* (1897); *Songs and their Singers from 'Punch'* (1898); *Fifty Pen-and-Ink Sketches* (1899); *Phil May Album* (1899); *A Medley: Sketches in Colour and Black and White* (1903); *Sketches from 'Punch'* (1903); *The Phil May Folio: with a Biography* (1904); *Phil May in Australia* (Sydney, 1904); *Phil May Pictures* (1907); *A Picture Book* (1908); *Humorists of the Pencil: Phil May* (1908).

Meehan, JAMES (1774-1826), born in Ireland in 1774, was trained as a surveyor; for an offence committed in connection with the Irish rebellion of 1798 he was sentenced to transportation, and reached Sydney in February 1800. In April he was allotted as an assistant to C. . Grimes (q.v.), then deputy-surveyor-general, whom he accompanied in 1801 to the Hunter River and in 1802-3 to King Island and Port Phillip, thus being one of the first white men to stand on the site of Melbourne. In October 1803 Governor King sent him to make surveys for Bowen at Risdon Cove in Tasmania; but six months later he was brought back to Sydney to fill the place of Grimes, who had gone on leave in August 1803.

From this time until his retirement in 1822 Meehan carried out all surveys for land-grants —a duty which involved a number of genuine explorations in new country, one of which took him across very rough country between Moss Vale and Wellington in 1820. King recognized his meritorious work by the grant of a conditional pardon in June 1805, and of a full pardon exactly 12 months later. On Grimes's return in 1806 Meehan was sent to Hobart; but the next year, when Grimes was ordered to England by Colonel Johnston, Meehan returned to New South Wales and worked there as acting-surveyor-general till Macquarie's arrival. His map of Sydney, published in 1807 and reproduced in vol. vi of the *Historical Records of New South Wales*, is a record of great value. For his services Foveaux (q.v.) made him a grant of 130 acres at Bankstown. Macquarie (whom he accompanied to Tasmania in 1811) was greatly impressed by his excellence both as a surveyor and as a man, and appointed him deputy-surveyor-general in 1812 under Oxley, with whom he worked amicably and strenuously until 1821. In that year—probably because Macquarie himself was retiring—he sent in his resignation, with an appeal for a pension which was strongly endorsed by Macquarie and Oxley; £100 was granted, but he did not enjoy it for long, dying on 26 April 1826 near Liverpool in New South Wales.

The value of his 22 years work in the colony is sufficiently proved by the eulogies of Oxley, Macquarie ('there is not a more useful officer serving under this Government. . . his honour and integrity are unimpeachable'), and even Bigge, who was prejudiced against him as an ex-convict, coupled him as an explorer with Oxley and Evans—praise which (as reference to the article on EXPLORATION BY LAND will show) is over-stated, though in the minor explorations of 1815-21 he had played a considerable part. For an account of his exploration between the Wingecarribee, Shoalhaven, Macquarie, and Murrumbidgee rivers see *Journal and Proceedings* of the Royal Australian Historical Society (vol. vii, Sydney, 1921).

J.W.

Megaloptera, an order of insects dating from early geological times, but represented at the present day by little more than 200 species, of which (so far) only three have been described from Australia. There are two sub-orders, the Sialoidea (alder-flies), whose larvae are aquatic, and the Raphidioidea (snake-flies), whose larvae live under the bark of trees. These latter are not found at all in Australia. The larvae of alder-flies may be recognized by the possession of a series of paired lateral appendages on the abdomen; these appear to function as gills. The pupa lies free in the earth. The imagines closely resemble lacewings in structure, but may be distinguished by the absence of the terminal splitting of the veins which is so characteristic of the Planipennia. The order Megaloptera is, however, only doubtfully distinct from the Planipennia, the two groups of insects being very near akin.

The Corydalidae consist of large insects whose larvae have an abdomen terminating in a pair of hooked claspers. A single species, *Archichauliodes guttiferus*, is not uncommon in most parts of Australia, its larva being found under rocks in mountain streams. The Sialidae are smaller, and resemble caddis-flies in appearance, but have the mandibulate mouth-parts complete; the abdomen of the larva terminates in a single caudal filament. Two species,

Austrosialis ignicollis (plate xix, fig. 23) and *Stenosialis australiensis*, have been described, the former from Tasmania, the latter from Mount Tambourine near Brisbane. A smaller species of the last-named genus is not uncommon around Sydney, but has not yet been described. These species are related to Chilean forms.

See Tillyard in the *Proceedings* of the Linnean Society of New South Wales (1918). R.J.T.

Megapodiidae. See MOUND-BIRDS.

Melaleuca, an almost exclusively Australian genus of plants of the family Myrtaceae, mostly shrubs and small trees, known as tea-trees, and usually found in marshy places. The flowers are red, crimson, white, or yellow, in heads or spikes; where spikes (bottle-brushes) occur, the shoot grows through and beyond the flowers, and the fruits form in a cluster round

M. leucadendron.

the branch. The calyx-tube is bell-shaped, with imbricate lobes; petals five, orbicular; stamens united into five distinct bundles, the united part being flattened; capsule enclosed in the hardened calyx; leaves opposite or alternate. Each season a new set of capsules is produced, but they remain attached to the branches for two or three years to give the seeds time to ripen. From *M. leucadendron* comes the cajuput oil of commerce, and several other species yield essential oils of greater or less value. *M. ericifolia*, a shrub, covers large areas of marshy land in most of the southern States; in Tasmania it becomes a tree, reaching a height of 70 feet with a girth of 4-5 feet; its bark was used by the natives of Tasmania for making canoes, sheets being stitched together with the outer skin of a sort of marsh-mallow, *Sida pulchella*. Near Sydney there exists a purplish-flowered variety of this species. *M. armillaris* makes a good protective hedge in exposed situations, and several of the white-flowered species are highly ornamental. The smaller species display a profusion of pretty flowers, and some coastal species which attain tree-size are rounded and beautiful in shape. Most species have small, neat leaves; *M. leucadendron* is typical of the section with comparatively large lanceolate leaves.

The timber of most species of *Melaleuca* is exceptionally well-suited for posts in wet ground, or for boat-building, since moist conditions do not readily affect it. From the papery bark of several species the aboriginal women made a creel for carrying their babies in; it is impervious to water, and durable, and has been used for bottle-stoppers, for lining boots and shoes, and for packing fruit for export (but with indifferent success so far). This bark has also been used in conjunction with timber in making dams, and has been found still sound when the timber had decayed.

Melanesia, MIGRATIONS IN.—This is probably the most complicated ethnological region in the world, since it has the most diversified environment and yet is near to what is generally accepted as the centre of dispersion in Asia. Hence the later races have pressed out into the island areas, while the older races have been preserved, on many of the larger islands, only in isolated mountain areas clothed with tropical jungle. The table on page 50 shows the major races with their ethnological characters; the early primitive races are given below, and the younger, more advanced races above. The numbers correspond to those on the migration-zones in the accompanying map.

Cephalic index is taken as the first criterion in establishing ethnical types. Such a classification splits up the eastern island-peoples (Polynesians)—e.g. Maoris and Samoans—into different classes, and allies the Maori with the Massim of Melanesia. This is logical, since the term 'Polynesian' is based on habitat, language, and culture rather than on anything physical; and we should not classify Booker Washington as a non-negro because his culture and language are exactly those of the educated western European.

As regards some of the lower races classification is not so difficult; the negrito and Australian groups are distinctive, and the Papuan races have fairly definite characters. But the so-called Melanesian peoples are especially hard to classify satisfactorily. Finally, the higher races on the frontiers of Asia are late-comers into the Australasian region, and can be correlated with certain Asiatic types with some certainty.

The negrito peoples are scattered through a belt of 'marginal' habitats from the Andaman Islands to Tasmania. With the exception of these two extreme regions, all their localities may be described as 'inliers.' In other words they have been almost overwhelmed by succeeding immigrations, which have in every case driven them into forested highlands. The Mincopi people of the Andamans in the Bay of Bengal, and the Tasmanians, were preserved up to recent times by their isolation in islands about 200 miles from the mainland. In the map given on page 51, the main corridor, used probably by all the early peoples, extends from Siam towards Papua and Cape York. In Pleistocene times this traversed level plains for much of its

course. Since then, Sunda-land (north of Java) and Sahul-land (west of Darwin) in the north have vanished, and in central Australia the 'corridor of migration' has in all probability greatly deteriorated in attraction. The present habitat of the negritos is found to lie off the main 'corridor,' in general far to the east, in the high ranges which once bordered fairly continuous East Indian lands. Each group of these peoples branched off from much the same main corridor; probably, therefore, the Tasmanians separated from the negritos now living in Melanesia (the region from New Ireland to New Caledonia) somewhere near Timor or Celebes. So also the Aeta of the Philippines probably branched off from the main corridor near western Borneo.

GENERALIZED SCHEME OF RACES IN THE AUSTRALASIAN REGIONS.

No.	Race.	Types.	Cephalic Index.	Hair.	Stature. Inches.	Skin.	Nose.	Culture.
6	Indonesian ...	Javanese	83-85	straight to wavy.	63	brown ...	mesorrhine.	metals, weaving, &c.
5	Later Polynesian ...	Samoan, Tahitian	76-84	,, ...	68	light brown.	,,	
4a	North Melanesian...	Massim	77	wavy ...	65	dark brown to black.		
4	Mid-Melanesian ...	North Solomons ...	75	,, ...	63	,, ...	platyrrhine.	neolithic, megaliths, couvade.
3	Australian ...	Arunta Kamilroi ..	73	,, ...	65	chocolate	,, ...	neolithic, primitive weaving, no metals or pots.
2a	South Melanesian ..	New Caledonia ...	72	frizzy ...	65	dark brown.	,,	
2	Papuan	West Melanesia, West Papua.	71	,, ...	63	,, ...	,,	
1	Negrito	Aeta, Tapiro, Tasmanian (in part).	Variable ..	,, ...	58	,, ...	,, ...	very primitive, palaeolithic.

In Melanesia negritos remotely allied to the Tasmanian aborigines occur in very small groups in the interiors of the largest islands. In many cases the pure-bloods have become practically extinct, and the chief evidence of a former negrito settlement is the presence of tribes of smaller stature than usual, often with rather higher head-indices than those of the surrounding tribes. Indeed, as the negritos of this region become less pygmy-like their head-index decreases, as the following table shows:

Group.	Tribe.	Cephalic Index.	Stature.	Hair.	Skin.
			ft. in.		
Asiatic Negrito ...	Aeta (Philippines)	79·6	4 9	peppercorn	chocolate.
	Mincopi	82·1	4 11	,, ...	black.
	Semang (F.M.S.)...	76	5 0	,, ...	chocolate-brown.
	Tapiro	79·5	4 9	frizzy ...	yellow-brown.
Mixed types ...	Sakai (F.M.S.) ...	79	4 11	wavy ...	black.
	Tasmanian ...	74·77	5 5	frizzy ...	dark brown.
	Veddah (Ceylon) ...	73·75	5 1	wavy ...	chocolate.
(For comparison)...	Australian ...	73	5 5	wavy ...	chocolate.

The most probable explanation is that we are dealing here with two original stocks, best illustrated by the Australian and the Aeta, and the Tasmanian is probably a half-caste between the two. He has the stature of the Australian, the hair of the Aeta, and an intermediate cephalic index. The Tapiro negritos have been investigated by Wollaston (see his *Pygmies and Papuans*). They live just to the south-west of Mount Carstensz in Dutch New Guinea at a height of over 7000 feet. Austen has found somewhat similar folk in the west of the British territory. They are active little fellows with big buttocks and big calves, quite unlike the Papuans in the swampy coast-lands below them. The nose is straight but very wide; the upper lip long and curiously convex; the hair short, woolly, and black—the men have short, bushy, black beards. Their weapons are bows and arrows, flint knives, and daggers made from cassowary bones. Instead of mere wind-breaks, their houses are built on piles and made of lath and bark. They are therefore much ahead of the Tasmanians in culture.

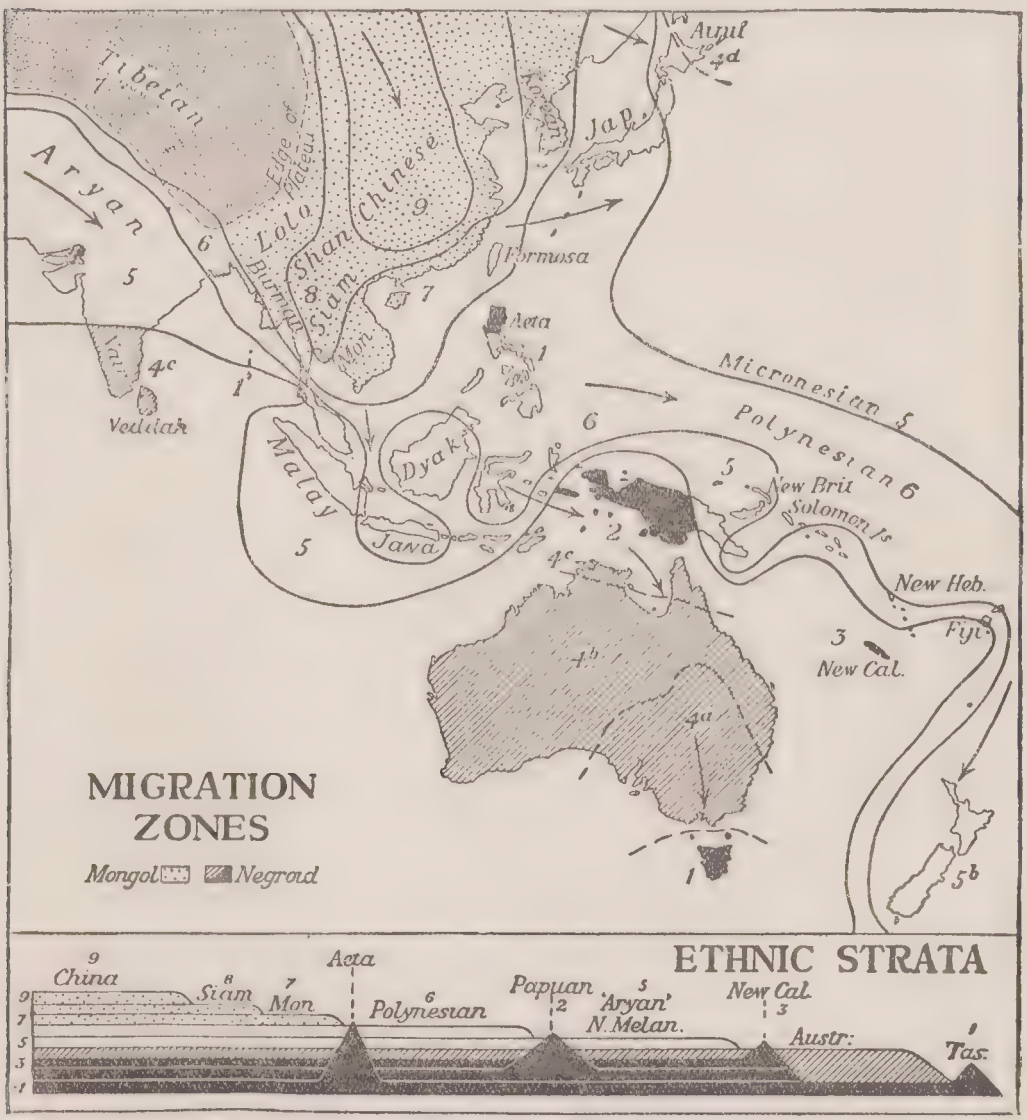
Quite distinct from the Australian aboriginal in many ways is a group of people whose present range is from Flores (400 miles east of Java) and the Moluccan islands on the west to Fiji and New Caledonia on the east. They are shown as zones 2 and 3 in the map.

In Melanesia they are found chiefly in the southern and western isles. In all cases the skin is very dark, in some parts even sooty in colour; the hair is extremely frizzy, the nose often hooked and Jewish in appearance, the face long, and the skull markedly dolichocephalic (73). There is often a well-marked brow-ridge (torus). In this ethnological division there is a well-defined linguistic distinction between the peoples of New Guinea in the west and those inhabiting Melanesia to the east; the easterners' languages belong to a common Melanesian stock, the westerners speak quite different and very varied languages, which are described for convenience as Papuan. (Similarly in Africa the Bantu negroes use varieties of a common Bantu language, whereas the Sudan tribes, otherwise somewhat similar, speak innumerable alien tongues.) Judging by analogy, we may consider all these long-headed negroes as of

similar origin, and as migrating from Asia about the same time; but possibly those living in the small islands came under the influence of a great migration of later comers (the higher 'Melanesians') who spoke a new tongue which the primitive island folk adopted.

The salient feature of primitive Melanesian organization is the division of each tribe into two exogamous groups, each possessing a totem (which we may briefly describe as the tribal symbol); often one totem is light-coloured and the other dark. This may commemorate a racial mixture of aboriginal dark peoples with invaders less dark. Marriage takes place only between members of different groups, hence the name of 'primitive dual-group' Melanesians is given to this stock. Descent was usually reckoned through the mother. Body-scars (keloids) are thought to improve the appearance, just as in Australia. Magic plays a very large part in their lives, and they inter their dead in a crouched position. Secret societies of a complex nature terrorize the community, in which a ritual of masks and bull-roarers shows a culture-stage little different from the Australian (see ABORIGINES).

Living almost side by side with the primitive dual-group peoples is a much higher race, which has unfortunately also been classified as Melanesian. They have few characters in common, though certain transition types are to be expected. The cephalic index is 76, as opposed to 73; there is no exogamy, and the physical features are much more refined. These higher races are smaller and lighter in colour; the skin ranges from bronze to *café-au-lait*; the hair is usually rather frizzy, but may be ringleted or wavy. The usual beverage is kava, prepared by macerating a root like ginger; much ceremony accompanies kava-drinking. In many respects



Migrations of aboriginal peoples into the Australasian area. The southern peoples (with lower numbers) are the more primitive. The section shows diagrammatically how the later peoples have overwhelmed the more primitive tribes.

they resemble the primitive peoples of Europe, the Ibero-Mediterraneans. Thus they tattoo in almost all the tribes, indulge in skull-hunting, build stone monuments, and observe the curious custom of the 'couvade,' whereby on the birth of a child the father takes to his bed for a space of days or weeks and abstains from certain foods and practices. All these customs characterized the earlier western Europeans (Irish, Basques, Corsicans, etc.) and may be traced in the earliest descriptions of them when in a state of barbarism.

These higher Melanesians are chiefly found in the northern and eastern islands. Dolmens and stone circles mark their migrations, and occur in New Britain, in eastern New Guinea, in the Solomons, and in the New Hebrides. We can only trace the Melanesian migration from anthropometric or cultural evidence. Their legends are of no such value as those of the Polynesians, for instance. Almost everywhere where Polynesians settled we find traces of the lower races, and it seems likely that they or their allies wandered from Madagascar to Easter Island; for some authorities consider that certain negroid tribes who preceded the Hovas (an early Indonesian race) in Madagascar also came from the East Indies. As regards Easter Island, although it lies 5000 miles to the east, the evidence advanced in Mrs. Routledge's *Mystery of Easter Island* (London, 1919) shows that the slit-eared statues differ little (except in size) from similar figures in Melanesia. Their bird-cult recalls that associated with the frigate-bird in the Solomons.

The Polynesians comprise several ethnic stocks allied in much the same fashion as are the Alpine and Nordic peoples of Europe; they have a common language, culture, and environment, but are not in a physical sense people of the same race. There is the greatest difference between the dark, medium-sized, leptorrhine, long-headed Maori and the fair, tall, somewhat platyrrhine and very brachycephalic Samoan. Physically, the former approaches the western European, the latter is nearer the so-called Mongolian; and this resemblance is no accident, but illustrates an important general principle. In effect, while one group of peoples was migrating to the western periphery of Asia (e.g. Britain), an allied group was migrating to the south-east, and reached about the same position with regard to central Asia (e.g. outer Polynesia). Thus we find the peripheral folk of Hawaii (in the north-east) and New Zealand (in the south-east) linked together in certain physical and cultural aspects. Both peoples have heavy beards—which are absent in most Polynesians. Indeed it is almost impossible to distinguish some Hawaians and Maoris from certain dark Europeans.

The Polynesians are as a whole some of the tallest people in the world; 5 feet 10 inches is quite a usual height. The higher Polynesians have often a very light brown skin; Hawaians and Maoris are a much darker brown. The hair is wavy to straight and of the same type as European hair, but always black in colour. There is a tendency to obesity. The face has regular features—so much so that many of the women are quite beautiful. The eyes are black. Tattooing is common, and has reached its greatest development in New Zealand. The Igorots of the Philippines, and many of the highest Melanesian folk of New Guinea (whom the writer places in the same zone), were their rivals in this respect.

There is little doubt that the Polynesian peoples represent a disrupted zone of races who originally inhabited south-eastern Asia. Judging by the general laws of migration, we should expect to find their congeners still living in the highlands of India and Burma on the one hand, and in Manchuria or thereabouts on the other hand; many allies might be expected in America. This is precisely what we find when we examine the physical and cultural evidence. We may picture a time—perhaps reaching back to the early Neolithic period—when the Polynesians and other tribes at the same stage of evolution occupied eastern Asia. Later on, during thousands of years, the Polynesians were slowly pushed to the sea by the Chinese and allied folk. For centuries the Polynesians occupied eastern China and Further India, and no doubt became expert navigators. Intense desiccation in central Asia drove out most of the 'Mongolians,' and they spread down into the coast-lands, probably about 5000 years ago. The Polynesians then abandoned the mainland and migrated eastward; a few went south and settled in the Mentawei isles of Sumatra (for here the Nias tribes speak a Polynesian tongue), but most kept north of Indonesia, and swept to the east without occupying islands already fairly fully occupied by the lower races (Negroes, Australians, and Lower Malays).

In Melanesia the Polynesian wave (as shown on the map) broke upon the eastern flank. Outlying colonies are found in the south of the Solomon Islands, as on Rennell Island. Tucopia, to the south-east, is Polynesian in type. So also in the southern islands of the New Hebrides (from Efate to Tanna) there have apparently been settlements. Off New Caledonia the people of the Loyalty group are largely of Polynesian stock. The Maoris are referred to above.

Gr. T.

Melba, Dame Nellie (Helen Porter Armstrong, *née* Mitchell), was born at Burnley near Melbourne on 19 May 1861 and attended for a time at the Presbyterian Ladies' College, Melbourne. She developed musical leanings at a very early age, but was uncertain of their direction. At first she took lessons in pianoforte-playing from Madame Charbonnet-Kellermann (mother of Annette Kellermann the swimmer); at her school she was taught singing on the supposition that she was a contralto. But Pietro Cecchi, who taught her from 1879 to 1886, decided that she was a soprano, and cultivated her voice on those lines. In 1882 she married Charles Armstrong, son of a Queensland squatter, and soon afterwards—against the wishes of her family—took up singing at concerts and toured eastern Australia with Charles Huenerbein, meeting with little success. In 1886 she left Australia for Paris, where Maurice Strakosch was struck by the quality of her voice and helped her to obtain tuition from Madame Marchesi, then the foremost vocal teacher of western Europe. On 15 October 1887 'Nellie Melba' (the name is, of course, an adaptation of that of her birthplace), made her début at the Théatre de la Monnaie in Brussels as Gilda in *Rigoletto*, and on 24 May 1888 appeared under the direction of Sir Augustus Harris at Covent Garden as Lucia in *Lucia di Lammermoor*. During the season she sang the rôles of Juliet (*Romeo et Juliette*), Elsa (*Lohengrin*), and Marguerite (*Faust*), and by the end of it had established herself as a great singer, though her acting was considered 'cold.' In 1889 she re-

peated her success at the Paris Opera House and in 1890 at the Milan Scala, thereafter touring Holland and Scandinavia. In 1891 she appeared in Russia and Italy. In 1893-4 she toured the United States, and at the end of 1894 returned to Covent Garden. During these years she was still experimenting with her voice, attempting both Italian and Wagnerian parts; but her appearances in Wagner operas were rarely successful, and from 1894 on she wisely restricted herself to lyric rôles. In 1902 she revisited Australia to give a series of concerts, which suffered a good deal from her extraordinary temperamentalism; her voice, however, was at its best, and her reception when she sang was thoroughly appreciative. Returning to Europe, she achieved triumph after triumph, being reckoned the undoubted queen of the lyric stage. In 1911 she arranged with J. C. Williamson and Co. to bring to Australia a Grand Opera Company which played to crowded houses in the capital cities. During the war she raised by concerts and other means over £100,000 for Red Cross purposes in the United States, Canada, and Australia. After the war she returned to Covent Garden, and in spite of a serious illness in 1922 brought a second opera company to Australia in 1924; on 13 October 1924 she bade farewell to the operatic stage in Australia at a gala performance of *La Bohème* in Melbourne. Her farewell to Covent Garden audiences took place before the King and Queen on 8 June 1926, when her items included the balcony scene from *Romeo and Juliet* with Charles Hackett as Romeo. (D.B.E., 1918.)

See her autobiography *Melodies and Memories* (London, 1925) and Murphy (Agnes G.) *Melba: a Biography, with chapters by Madame Melba on the selection of Music as a profession* (London, 1909).

Melbourne, the capital of Victoria and in population the second city in the Commonwealth, did not, like other Australian capitals, originate under official auspices. It owes its birth to the enterprise of some settlers from Tasmania, where the country available for pastoral purposes was becoming overstocked. In May 1835 John Batman (q.v.), as agent for the Port Phillip Association, crossed the straits from Launceston in the schooner *Rebecca,* and explored westward and northward of Port Phillip. He fell in with a wandering band of blacks, from whom he 'purchased' 600,000 acres of land, giving blankets, tomahawks, flour, etc. in payment; and having established a depot at Indented Head, near the entrance to the harbour, where he left some of his men, returned to Tasmania to prepare for a transfer to the new country. A few weeks later an independent party organized by John Pascoe Fawkner (q.v.) entered Port Phillip and made their way up the Yarra to the site of Melbourne, where they established a camp about the beginning of September 1835. Here they were found by John Helder Wedge (q.v.), a member of the Port Phillip Association, who had come over to inspect Batman's 'purchase;' as they refused to move from what Wedge considered to be the association's territory, he brought some of the Batman party up from Indented Head to camp alongside of them.

Not only was there a personal dissimilarity between the two leaders, Batman and Fawkner; there was as much between their respective associations. Batman's was composed of business men, ex-civil-servants, pastoralists, and professional men, while Fawkner's party was made up of tradesmen, mechanics, and labourers. Among Batman's associates were Charles Swanston (a banker), J. T. Gellibrand (a lawyer), John Helder Wedge (a surveyor), J. and W. Robertson (drapers), James Simpson (a police magistrate), John Thomas Collicott (a postmaster and auctioneer), and other men prominent in Tasmania. Batman brought over the first doctor, the first preacher, and the first school-teacher. In Fawkner's party there were Samuel Jackson (a contractor who became one of Melbourne's earliest architects), George Evans (a plasterer and builder, who built the first sod hut), Robert Marr (a carpenter), and James Gilbert (a blacksmith). Charles Wise, one of the party, ploughed the first field cultivated in Port Phillip. The one party seemed to be the complement of the other. Thus was the nucleus of Melbourne formed.

Governor Bourke, as in duty bound, repudiated the validity of Batman's purchase from the natives, and condemned as trespassers those who had dared to intrude upon crown lands 'without the licence or authority of His Majesty's Government;' but in a despatch to Downing-street he expressed the opinion that it would be 'more desirable to impose reasonable conditions on Mr. Batman and his associates than to insist upon their abandoning their undertaking.' In May 1836 he sent a police magistrate to inspect the new settlement, which then consisted of 'three weather-boarded, two slab, and eight turf huts;' and in the following September, having obtained the approval of the colonial office, he despatched thither an official party under Captain William Lonsdale, who was to act as resident magistrate. This party included surveyors who were to map out the shores of the harbour, trace the courses of rivers, and subdivide the district for purposes of sale.

In March 1837 Bourke visited the settlement and authorized the laying out of a town on the site the settlers had selected; Lonsdale preferred a site at the mouth of the Yarra, but lack of a water-supply at the time made it ineligible. Bourke seems to have in his own mind agreed with Lonsdale, for to the Yarra-mouth site he gave the name Williamstown after the reigning monarch, whereas the more inland site was named Melbourne after the then prime minister of England. The infant town had no lack of names; the Tasmanian newspapers called it 'Batmania' and 'Glenelg'—the latter on the analogy of Sydney and Hobart, after the British secretary of state for the colonies; and Stewart wrote of it as 'Bearbrass,' while other contemporary references give the forms 'Bearport,' 'Bareheep,' and 'Bearbury' all apparently variations of the native name of the locality, which was 'Berrern' or 'Bararing.'

The infant town was laid out on a rectangular plan, with streets intersecting at 10-chain intervals. Though Robert Russell had surveyed the district, it was due to the foresight of Robert Hoddle (q.v.) that the streets were made 99 feet wide, though at that time one chain (66 feet) was considered the correct width for a main road. To Hoddle Melbourne owes also the boulevards of St. Kilda-road running southwards, Victoria and Wellington parades running eastwards, and the Flemington and Sydney roads running northwards from its outskirts. The names of the streets recall early history. Flinders-street is named after Matthew Flinders, who was the second commander to enter Port Phillip; Collins-street after Captain David Collins, who founded the first settlement in Port

MELBOURNE AND SUBURBS.

Phillip—Hobart Camp, which lasted only a few months, on the site where Sorrento now stands—Bourke-street after Bourke himself; Lonsdale-street after Captain Lonsdale. Latrobe-street was named later, after the first superintendent and governor. The direction of these streets is not due east and west, but rather in line with the Yarra. The original town went only as far north as Lonsdale-street, though in the other direction it ran to the full extent from Spencer-street to Spring-street. Spencer-street was named after Lord Spencer, who was in Melbourne's cabinet; King-street after Governor King; William-street after the reigning monarch, and Queen-street after his queen; Elizabeth-street after the wife of Richard Bourke; Swanston-street after Captain Swanston, a pioneer and a member of the Port Phillip Association; Russell-street after Lord John Russell; Stephen-street (now Exhibition-street), after an under-secretary at the colonial office; and Spring-street after Spring Rice, the chancellor of the exchequer. Between these streets were laid out narrower lanes, such as Flinders-lane and Little Bourke-street; this arrangement has proved to be an error, conducing to a congestion of modern traffic which calls for drastic remedies in the future. The first sale of town allotments took place on 1 June 1837, just two years after Batman's landing.

Melbourne was founded at a particularly auspicious moment. Pastoralists from Tasmania were already spreading their flocks and herds over the western plains of the Port Phillip district, and 'overlanders' pushed across the Murray from the north as soon as the opening of a new port was assured. By 1841 a vigorous and thriving community of over 4000 souls had been established on the Yarra, and a demand had arisen for the separation of the district from New South Wales. Melbourne was incorporated in 1842, and by 1845 permanent government offices, a customs house, post-office, court-house, several churches, and a theatre had been erected; the town became a city on the arrival of the first bishop of Melbourne (Charles Perry, q.v.) in 1848. The census of March 1851 showed a population of over 20,000. A few months later the discovery of gold at Castlemaine, Ballarat, and Bendigo gave an impetus to the colony's development which crammed into half-a-dozen years the normal growth of a generation. Melbourne soon surpassed even Sydney in size, and for more than 40 years was the most populous city in Australia.

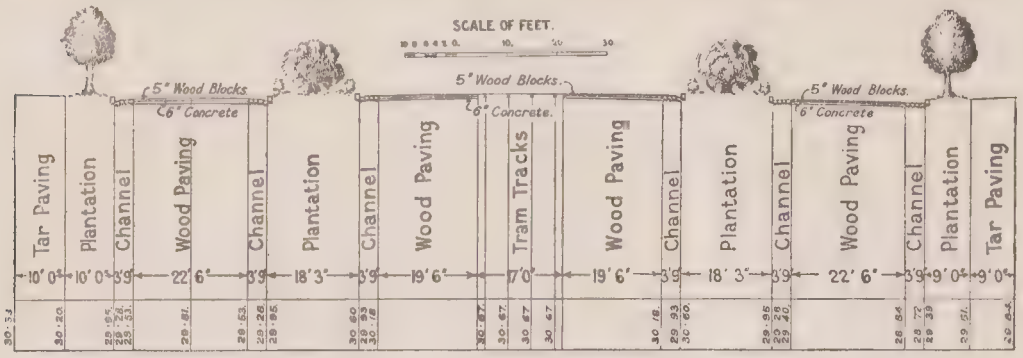
The rush of gold-seekers in 1852 and 1853 rapidly overcrowded the town and encircled it with encampments of immigrants unable to find house accommodation. The most famous of these was 'Canvas Town,' on rising ground south of the Yarra. In 1854 the foundation-stones were laid of a university and a public library; a railway (the first in Australia) was opened from Melbourne to Sandridge (now Port Melbourne); telegraphic communication was established with Williamstown on the opposite shores of Hobson's Bay; and in a miniature 'Crystal Palace,' erected in ten weeks, the first Melbourne Exhibition was held. The streets were provided with metalled roadways and paved foot-walks, and in 1857 were lighted by gas; and the completion, about the same time, of the Yan Yean system provided the citizens with a water-supply, for which they had hitherto been compelled to rely upon the Yarra. To this period also belongs the growth of the coaching business, with which was associated for so many years the name of Cobb & Co. (see RUTHERFORD, JAMES). Before the end of 1851 coaches from Melbourne to the goldfields had been run by two hotel-keepers located at Bacchus Marsh; but it was Freeman Cobb and his American associates who in 1854 laid the foundation of the famous Australian coaching system, though Cobb himself left Australia in 1856.

The expansion of the suburban area was a natural concomitant of the enormous influx of population. Williamstown, situated at 'the anchorage' on the western shores of Hobson's Bay, was the first suburb, its foundation being contemporaneous with that of Melbourne. The sale in 1839 of 25-acre blocks lying east and north-east of the town gave rise to 'Newtown' (subsequently named Fitzroy and Collingwood) and Richmond. 'Liardet's Beach' at the mouth of the river, across the bay from Williamstown, boasted a couple of public-houses and a few fishermen's huts by the end of 1840, and from this beginning developed Sandridge, now Port Melbourne. The watering-places of St. Kilda and Brighton were established in 1841 or 1842; about the same time the first stopping-place on the northward road to Sydney acquired the name of Brunswick; a few years later the brick-making industry, which had previously flourished on the south bank of the Yarra, was transferred thither and Brunswick began its career as an industrial suburb. The foresight of early survey authorities had made provisional reserves of park-lands north, east, and south of the town (progress on the west being blocked by the existence of 'Batman's Swamp'—now excavated to make the Victoria dock), but in 1852 these reserves were to some extent encroached upon by the laying-out of the inner suburbs of Carlton, Parkside (now North Melbourne), and Emerald Hill (now South Melbourne). Communication with the southern side of the river was established by the erection of bridges in 1846 and 1850 (see LENNOX, DAVID); in the fifties the parish of Prahran began to lose its rural character, and on the high banks of the Yarra, opposite Richmond and Collingwood, the fashionable residential areas of Toorak, Hawthorn, and Kew came into existence. North-west of Melbourne, on the highway to the goldfields (the Mount Alexander road), sprang up Flemington and Essendon, the former adjoining the race-course on which the Melbourne Cup has been run ever since 1861; and between Flemington and Williamstown was established the manufacturing district of Footscray. In 1855 and 1856 Collingwood, Richmond, Prahran, St. Kilda, South Melbourne, and Williamstown were proclaimed separate municipalities, and by 1861 railway communication was established with St. Kilda, Richmond, Hawthorn, Prahran, Brighton, Essendon, and Williamstown.

Progress in the sixties and seventies was steady, if not spectacular. The earlier churches were gradually replaced by edifices of a size and dignity more in accord with the importance of the city; a vice-regal residence (imitated from the royal residence, Osborne in the Isle of Wight (was erected in the Government Domain south of the Yarra; the Elizabeth-street post-office, the law-courts, and a branch of the royal mint were built, as well as the treasury and government offices at the eastern end of Collins-street; a new town-hall arose on the site of the old blue-stone building erected during the 'gold-rush' times. An organized omnibus service on American lines supplemented the cars and wagonettes which plied for hire in the

streets; the improvement of the Yarra's winding course was seriously taken in hand.

The decade 1880-90 was marked by substantial progress. Population increased from 282,000 in 1881 to 490,000 in 1891. Two great international exhibitions were held (in 1880 and 1888) in a building specially erected in the Carlton Gardens. Telephones and electric light were introduced in the early eighties, underground drains were constructed to carry off storm-water (which had hitherto proved very troublesome in the low-lying part of the town),



Cross-section of St. Kilda-road, Melbourne.

and wood-paving began to replace macadamized roadways. Blocks of office buildings, eight and nine storeys in height, towered over the older structures whose maximum was three or four. In 1885 was inaugurated the system of cable tramways which, after serving Melbourne for 40 years, was only in 1925 being supplanted by electric traction (though in the suburbs that system had prevailed for some years). The course of the Yarra was widened and straightened so as to eliminate floods, which had been a constantly recurring trouble up to 1891; and between 1885 and 1889 two new bridges—Queen's Bridge and the present Prince's Bridge—were thrown across the river. Fresh suburban areas were also developed east and south-east of the town, following on the expansion of the railway-system. The linking up in 1879 of the Gippsland line with that from Brighton supplied railway communication to the now populous areas of Malvern and Caulfield; the opening of the Box Hill railway in 1882 brought into being the 'eastern suburbs' of Camberwell, Canterbury, and Surrey Hills in what had been the dairy-farming and market-gardening district of Boroondara.

Later improvements include the inauguration of a sewerage-system in 1891; the erection of the central railway station in Flinders-street (which now deals with over 13 million passengers a year) between 1904 and 1909; the introduction of electric tramway services in the suburbs, which commenced in 1906; and the electrification of the suburban railway-lines, on a scheme initiated in 1918. The population of Melbourne, which stood still for a time after the collapse of the 'land boom,' and had not quite reached half a million at the close of last century, was estimated at the end of 1925 to be 912,130, spread over an area of about 250 square miles.

Among Melbourne's early merchants were such enterprising spirits as Craig, Jackson, Rucker, Welsh, Graham, Nodin, Heape, and Grice. The better part of the town was then (as it is not now) in the west; business naturally settled itself in the centre of the city. Doctors began to affect Collins-street in the forties, and Collins-street-east is now almost devoted to that profession. Collins-street-west, with Queen-street, has became the home of the banks, insurance companies, and similar institutions. Flinders-lane (commonly known as 'the Lane') houses the chief importing firms. The principal shopping thoroughfares are Bourke-street, Swanston-street, Elizabeth-street, and 'the Block' in Collins-street.

In and about Melbourne there are fine examples of modern road-construction. The main St. Kilda-road, which runs from Prince's Bridge to St. Kilda, consists of a series of roads and footpaths, separated by ornamental plantations of palms and trees. The overall formation is three chains wide, made up of a central wood-blocked roadway 63-ft. 6-in. wide, carrying a double-track tramway; two 30-ft. carriage-ways also wood-blocked; and footpaths of tarred paving, one 10-ft. and one 9-ft. wide. The plantations have an aggregate width of 55-ft. 6-in., the two central ones being each 18-ft. 3-in. wide, and the two bounding the footways 10-ft. and 9-ft. respectively. The Sydney-road running north from Melbourne is also three chains wide over all, with four plantations of ornamental trees, but the trees are planted in openings set back in the footways six feet from the kerbing. The central roadway is 53-ft. wide between the 15-ft. wide plantations; is wood-blocked on six inches of concrete, and carries a double-track tramway. On each side of the plantations are carriage-ways, 24-ft. wide between kerbs. The footways, which are ornamented with shade trees, are exceptionally wide, being 33-ft. 6-in. each.

The monument which formerly stood over Batman's grave in the old cemetery has been transferred to Batman-avenue near the banks of the Yarra. Batman founded a free city, and it was kept free. John Charles King, the first town clerk, was sent to England to memorialize the British government against transportation. When Governor FitzRoy was on a visit to Melbourne the *Randolph* came in with transported convicts, but Latrobe refused to allow them to land, and FitzRoy saw that he could not force such denizens upon Melbourne.

Although built on gently undulating country which readily lends itself to schemes of beautification—as is exemplified in the magnificent botanical gardens on the south side of the Yarra—the city is surrounded by a coastal

plain which provides no inspiring natural scenery, and the harbour of Port Phillip has no beauty-spots comparable to those of Port Jackson. But the Dandenong ranges, lying 20 miles to the east, are easily accessible by railway, and among the foothills in the Plenty Ranges to the north, and along the timbered reaches of the upper Yarra are many holiday resorts and 'week-end' homes for tired citizens, and a string of watering-places stretches for some 30 miles along the tea-tree-fringed eastern beaches of Port Phillip.

The public institutions of Melbourne include, besides those to whose origin reference has already been made, a national museum and art gallery, housed in the same building as the public library; five well-equipped hospitals, the oldest being the Melbourne Hospital, opened in 1848; half a dozen theatres; three benevolent asylums; literary, historical, scientific, artists' and musical societies; the botanical gardens already referred to, and extensive zoological gardens, situated in the Royal Park north of the city. The principal daily newspapers are the *Argus*, established in 1846, which absorbed older papers dating back to 1838; the *Age*, established in 1854; and the *Herald*, which has had a continuous existence since 1840, and has been published as an evening paper since 1869.

See Bonwick's *Port Phillip Settlement* (London, 1883); Labilliere's *Early History of Victoria* (London, 1878); Rolf Boldrewood's *Old Melbourne Memories* (Melbourne, 1884); Turner's *History of the Colony of Victoria* (London, 1904); Selby's *The Old Pioneer Memorial History of Melbourne* (Melbourne, 1924).

A.W.G.

Meldrum, DAVID MAX, born in Edinburgh in 1875 and brought to Melbourne in 1889, studied art at the national art school, where he won the travelling scholarship (see ART GALLERIES) in 1899. In Europe he devoted much attention to the old masters at the Louvre and exhibited at the Old Salon. Returning to Melbourne in 1913, he took pupils and preached a theory of art which is set forth in *Max Meldrum, his Art and Views* (1919); his influence may almost be said to have founded a 'Meldrum school.' In practice his theories have produced some excellent still-life work and a group of exceptionally fine portraits, especially those of Sir Samuel Griffith (painted for the Commonwealth parliament), Sir Thomas à Beckett (in the Victorian law-courts library), and Archbishop Mannix. His landscapes, while often well painted, are usually too low in tone to suggest the character of Australian country. See ART.

W.M.

Meliaceae, a family of trees or shrubs abundant in the warm or tropical regions of America and Asia, but rare in Africa. Eleven genera with 45 species are indigenous to Australia. The largely tropical genus *Turraea* is represented by one indigenous species, *T. pubescens*, which extends throughout Malaysia. It is a small tree with white, sweet-scented flowers in short spikes or clusters, and an almost globular, furrowed fruit. It has a hard, close-grained timber, dark in the centre, with a bright yellow sapwood. *Amoora* is represented by one indigenous species, *A. nitidula*, a tall tree with a useful, light-coloured, tough wood. *Synoum* has two species endemic in eastern Australia. *S. glandulosum* (Dogwood or Bastard Rosewood), the 'wallaon' of the aborigines, is a small coastal bush-tree, reaching a height of 30 feet, with blush-pink flowers. When ripe the capsules open, and display seeds embedded in a bright red fleshy coat (arillus). The wood, when fresh, is deep red, and emits a rose-like scent. See DYSOXYLON, OWENIA, CEDAR, RED, and CEDAR, WHITE.

'Melville, Captain.' See MCCALLUM, FRANK.

Melville Island. See BUFFALO and NORTHERN TERRITORY.

Menindie Clover. See TRIGONELLA.

Mentha, a genus of the family Labiatae, chiefly extra-tropical, and most abundant in northern Europe and Asia. The species indigenous to Australia are endemic. *M. laxiflora* (Forest Mint) yields a pleasant oil like peppermint oil. That of *M. grandiflora* has a bitter and nauseous taste; that from the stems of *M. gracilis* smells like oil of peppermint with an admixture of pennyroyal. The supply of oil from the leaves is copious. The exotic *M. piperita* is the 'peppermint' of commerce.

Mercury. See MINERALOGY.

Meredith, LOUISA ANNE (1812-1895), daughter of Thomas Twamley, was born at Hampstead near Birmingham on 20 July 1812 and published her first book—*Poems with Illustrations*—in 1833; it, like most of her later works, was illustrated with her own drawings. In 1839 she married her cousin CHARLES MEREDITH (1811-1880), whose father had in 1821 been provisionally granted 2000 acres near Swanport in Tasmania and had a good deal of difficulty in securing the adjustment of his claims; those who care to follow up this matter may study it in *H.R.A.*, series III, vols. iv and v. Charles Meredith, who had for some time been managing a sheep-station in New South Wales for his father, brought his bride to Sydney, and after a visit to Bathurst (of which she left a vivid description) settled her in Wentworth's house at the head of Homebush Bay near Sydney. In October 1840 his father recalled them to Swanport; but the financial crisis of 1843 drove Charles to seek other employment, and from September 1843 to 1848 he was resident magistrate at Port Sorell on the north coast. In 1848 he returned to the Oyster Bay district, and in 1855 was elected by Glamorgan (the Oyster Bay constituency) to the Tasmanian legislative assembly. In the short-lived Gregson ministry of 1857 he was colonial treasurer, as also in the Whyte ministry of 1863-6, minister of lands under F. M. Innes in 1872-3, and treasurer and (for a month) minister of lands in the Reibey ministry of 1876-7. In 1879 he was made police magistrate at Launceston, and died there on 2 March 1880.

Louisa Meredith devoted a great part of her life to describing and illustrating the flora and fauna of Tasmania; her chief publications were *Notes and Sketches of New South Wales* (1844), *My Home in Tasmania* (1852), *Some of My Bush Friends* (1860), *Over the Straits* (1861), *Our Island Home* (1879), and *Tasmanian Friends and Foes* (1880), all illustrated with reproductions of her own drawings or water-colour paintings. In 1890 she returned to England to see through the press a second series of *Bush Friends*, which appeared in 1891. Coming back to Australia in 1892, she settled in Melbourne, and died there on 21 October 1895.

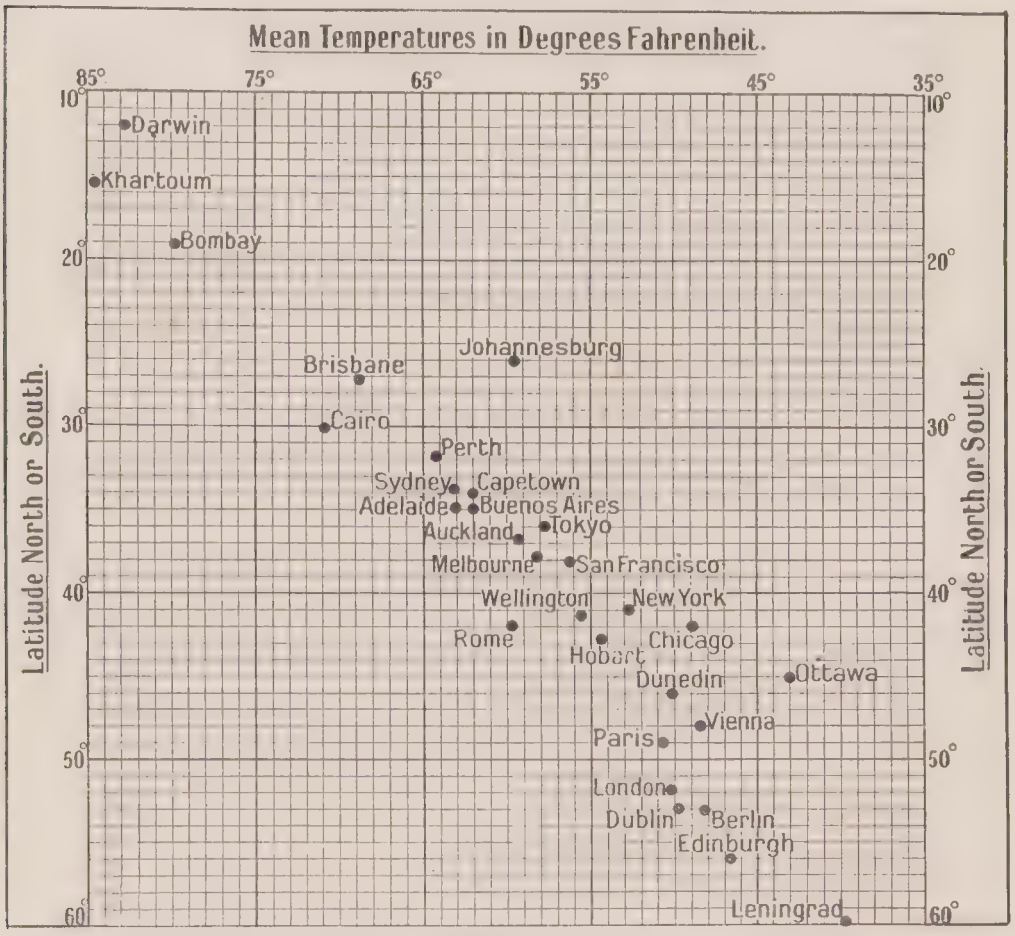
Meteorites. About 70 of these have been found, well distributed over Australia; of those that have been described 40 are siderites, 5 siderolites, and 19 aerolites. The largest, a siderite weighing nearly 3½ tons, was found at Cranbourne in Victoria; it is preserved in the natural history museum in London. Three—those found at Mount Brown, Emmaville, and Binda—were seen to fall. At Emmaville, New South Wales, a house was struck by a 5-oz. aerolite. The interesting pallasite group of siderolites, characterized by much olivine, is represented by no fewer than three falls—at Bendoc in Victoria, Molong in New South Wales, and Mount Dyrring in the same State. Particularly noticeable are four hexahedrites (ataxites) found in a narrowly circumscribed area in New England.

G.W.C.

Meteorology and Climate. The geographical position of Australia, its insularity, and the absence of geographical extremes, make its climate more pacific and equable than those of the other continents. Its northern limit lies 11° from the equator, its southern over 20° from the antarctic circle; these distances, and the influence of the intervening seas, considerably temper the severity of both heat and cold. Of its total area 1,149,320 square miles lie within the tropics and 1,825,261 square miles outside them.

Temperature.—The Australian seasons are:—summer, December to February; autumn, March to May; winter, June to August; spring, September to November. In most parts of the Commonwealth January is the hottest month, but in Tasmania and southern Victoria February is the hottest; in the tropical north, probably because the cooling monsoon rains occur in the late summer, December is the hottest month, and at Darwin November. Throughout Australia the coldest month is usually July. In the hottest months the mean temperatures range from 80° to 85° over all the northern and central regions, from 65° to 70° over the southern. In July only a very narrow strip of the northern sea-coast has a mean as high as 75°, the south ranging from 55° downwards. During the hot months the climate on the coast, except in the south, is invariably enervating. Inland, however, life is generally enjoyable; although the thermometer may in extreme cases rise to 120° in the shade, the dryness of the air and consequent rapid cooling of the skin by evaporation prevents serious discomfort except in the direct rays of the sun. Nocturnal radiation, too, is active inland, and the nights are invariably cool.

During some seasons parts of the continent are subject to prolonged heat-spells. At Marble Bar (a mining township in the north-west of



Mean temperatures of Australian capitals and of certain great cities elsewhere.

Western Australia) the maximum thermometer reached 100° and over, for 103 consecutive days in 1921-22. Nullagine, in the same region, recorded 100° for 57 days in 1900; Boulia, in western Queensland, for 76 in 1914-15; Charlotte Waters, in the neighbourhood of Lake Eyre, for 26 in 1922; and Charleville, in central Queensland, for 20 in 1889. Heat of this description is, however, confined to the interior. Perth has experienced a maximum temperature of 90° and over on 20 consecutive days; Adelaide 14; Melbourne and Brisbane, 8; Sydney, 4; and Hobart, 3.

Shade temperatures give only the actual temperature experienced by dry inorganic substances, not the sensible temperature felt by organic bodies. This difference is due, as already stated, to cooling by the evaporation of moisture from the skin by wind and heat, but more especially by the action of wind. To gauge for practical purposes the temperature of a country, we must take into account also the wet-bulb thermometer. A number of these have been distributed throughout Australia, and, although the period over which observations have extended is in some parts not long enough to determine definite normals, yet sufficient records have been obtained to establish fairly the influence of this climatic element. In no part of Australia is the wet-bulb temperature maintained at a reading sufficiently high to be detrimental to the health and physique of those engaged in outdoor labour. Investigations confine the 80° wet-bulb isotherm to a very narrow tract of country on the north-western coast of Western Australia during the months of December, January, and February; the 70° isotherm extends only to subtropical latitudes over comparatively small areas in Queensland and Western Australia during the same months and March; in southern Australia the readings are from 50° to 70°.

Broome, Port Darwin, and Thursday Island are the hottest centres, having a monthly mean temperature range of 16°, 8.4°, and 4.8° respectively. Thursday Island is undoubtedly the most monotonously warm area in the Commonwealth. Of the capital cities Brisbane is the hottest and Hobart the coldest, the others taking order between them as follows:—Perth, Sydney, Adelaide, Melbourne. The mean temperature range between the hottest and coldest months is between 18° and 23° in all these places.

A comparison of the mean temperatures of the capital cities of Australia with the cities of other countries is shown on the accompanying graph, which shows that Darwin is about 3° warmer than Bombay, but 2° lower than Khartoum: Brisbane is considerably (9.4°) above Johannesburg: Perth is about 7° lower than Cairo: Sydney slightly above Cape Town: Adelaide some 5° above Tokio: Melbourne a little over 2° in excess of San Francisco; and Hobart about midway between Rome and Chicago.

Taking Kalgoorlie and Broken Hill to represent conditions in the interior, we find the extremes much greater. Broken Hill's maximum of 78.3° in January falls to a minimum of 49.6° in July (a range of 28.7°), and Kalgoorlie's 77.3° in January to 51.2° in July (a range of 26.1°).

In subtropical areas insolation is more active over the eastern half than over the western during the early summer months, and more active over parts of the western coastal districts during the late summer months. In eastern Australia, too, the temperatures in the sub-tropics are about 1° higher than in corresponding latitudes in the west. North of the tropic these conditions are reversed, and between latitudes 17° and 20° the difference in excess is as much as 10° in favour of the west coast.

Frost and Snow.—Although observations have been taken continuously for a great number of years, no appreciable frosts have been recorded over all the northern coastal regions extending from Geraldton on the west coast right round the north and east coasts to Brisbane. In all other parts of Australia night frosts are severe and frequent, although of considerably varying periods. On the highlands in New South Wales, Victoria, and Tasmania, frosts of a more or less damaging nature have occurred in every month of the year. Over most of the wheat areas of South Australia, Victoria, New South Wales, and Queensland, they have been recorded between April and October; over north-central and north-eastern Victoria, the south and central western slopes of New South Wales, from April to November; over the Gascoyne and north-eastern parts of Western Australia and central Australia (if we may trust the diaries of explorers) from June to August; in central and western Queensland from June to July, June to August, or May to August; over the southern portion of Western Australia from April to October, or May to September.

Perennial snow is found only over sheltered crevices in the highest portions of the Australian Alps; there, however, during the winter months it accumulates to a depth of many feet, and by gradual thawing maintains a constant flow of water to the Murray and Snowy rivers throughout the year. During the winter period snow can always be expected along the mountain ranges in New South Wales, Victoria, and Tasmania, and occasionally on the

Australia: shaded where snow has fallen.

Mount Lofty ranges in South Australia. On rare occasions it has occurred as far north as Toowoomba in Queensland (latitude 27° 28′ S). Over the plain country it has been known to fall as far west as Louth on the Darling River, and over the whole of eastern and southern Victoria, except the immediate coast-line. In South Australia it has been recorded over a belt of country lying to the east of Spencer Gulf, about 200 miles long, running from north to south and 75 miles wide. West of the Gulf it has been noted at one place only—Yardea near Lake Gardner. In Western Australia it has been recorded on the hills in the extreme south-west, and at a few places on the southern goldfields.

The heaviest snowstorm on record in New South Wales occurred between 3 and 7 July 1900, extending from Congewar in the Hunter district to Condobolin and Warrumbungle, in the west. Railway traffic became paralysed, passengers being shut up in carriages and unable to reach hotels. In places the snow was 8 feet deep on the rails. At Bathurst many roofs, verandahs, etc., collapsed under its weight, and telegraph-lines were levelled everywhere. On 28 July 1901 the most widespread snowstorm occurred over south-eastern Australia, being practically general east of the 145th meridian. Another remarkable storm on 29 and 30 August 1905 extended from South Australia through southern Victoria and along the highlands of New South Wales to within 30 miles of the Queensland border.

On the mainland, Sydney and Melbourne are the only two capital cities that possess authenticated records of appreciable snow-falls. In Sydney on 30 June 1836 snow fell for half an hour, sufficient being on the ground to enable boys to make snowballs. Melbourne was covered with snow 7 to 12 inches deep on the morning of 31 August 1849. Another remarkable fall took place on 7 August 1899 between 1 and 2 p.m., when snow fell heavily in the Fitzroy Gardens, and snowballing was indulged in at the Scotch College nearby. A light to heavy fall also occurred over the north-eastern suburbs of Melbourne between 7 and 8 a.m. on 25 September 1905. Flakes of snow were observed in, or close to, Melbourne on 14 July 1840, 27 June 1845, 26 July 1882, 28 June 1900, 18 April 1910, and 21 June 1911.

Evaporation.—This is a climatic element second in importance to rainfall alone. To obtain data concerning its rate and distribution iron-jacketed tanks 3 feet in diameter, containing 130 gallons each, have been sunk at selected centres so that their tops are within an inch of the surface-level of the ground. In order that the exposed level may be fairly constant, and that the added water may not materially affect the temperature of the main body, the contents of each tank are replenished when or before a fall of 6 inches has taken place through evaporation. The information so far obtained is not very extensive, and observations have been made in some centres for a few years only; but a rough approximation to the times of equal evaporation and the aggregate annual amounts can be satisfactorily made. On the coast observations have been made for many years at the capital cities of the States, and at Rockhampton, Cooktown, Thursday Island, and Darwin. Inland there are stations at Marble Bar and Kalgoorlie in Western Australia, Alice Springs in the Northern Territory, Boulia in Queensland, and Broken Hill and Burrinjuck in New South Wales. At Broken Hill observations are made both with a tank at Umberumberka and on the evaporation from the Stephen's Creek reservoir a few miles away.

Evaporation Map showing amount of evaporation and Isatmics.

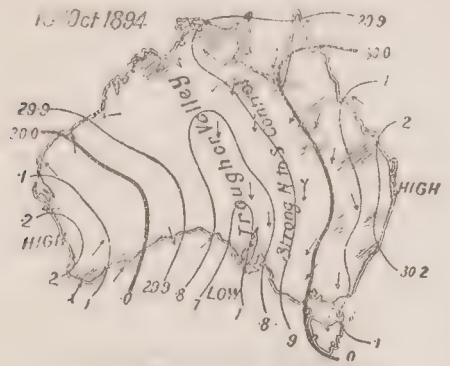
About a third of the continent—almost the same area which has an average annual rainfall of 10 inches and under—loses by evaporation from exposed water 100 inches and over per annum. During the summer months the daily rate all over Australia is considerable; inland from ½-inch to ¾-inch is often lost in a day, and losses of an inch and over have been registered. It follows (*a*) that shallow tanks and dams are practically useless, since the loss of half an inch over their wide area involves a great quantity of water, whereas that loss from the surface of a deep tank would be comparatively small; (*b*) that, if it is desired to receive any benefit from showers, every possible means of breaking up the surface-soil, even on grazing-land, must be adopted in order to let the rain through below the influence of surface-evaporation.

Rainfall.—The two main sources of Australian rainfall are the southern low-pressure systems (depressions) which skirt the southern shores of the continent mainly during the winter months, and the tropical low-pressure systems which operate chiefly in the summer months. A secondary but important source of supply is the anticyclone, which by inducing a flow of moist air from the adjacent ocean waters at any time during the year may bring about copious rains over the eastern littoral. Minor sources of rain are hurricanes (often incorrectly called 'cyclones') and tornadoes; but although these storms are characteristic of the country and result in heavy downpours, they cannot be regarded as staple or widespread givers of rain.

One of the most important rain-producing processes, at all events to Australian meteorology, is the movement of air from warm to cool latitudes and zones, causing condensation and finally bounteous precipitation over vast areas, with more or less disregard of the influence of land elevation or of barometric fluctuations. The characteristic isobaric conditions which precede or accompany this form of rain production are anticyclones of great dimensions and of considerable intensity, covering the eastern half of Australia, and perhaps an equal area of the ocean to the east. Their western isobars are comparatively straight, extending from Port Darwin to the southern ocean east of Spencer Gulf. The areas of low pressure that follow generally take the form of a shallow trough or valley, extending through the centre of Australia from the northern to the southern seaboards. A direct and rapid wind-circulation control extends from the equatorial zone to temperate latitudes, resulting in conditions particularly favourable for widespread and heavy downpours. The rainy season in Western Australia may be said to result almost solely from this physical action. The rain-bearing winds are northerly, precipitation becoming heavier as higher latitudes are reached. Rain visitations of this character are not infrequent; consequently, although rain-seasons may be irregular, relief from dry spells may occur long after the normal period for rain has passed. This peculiarity is a happy feature of

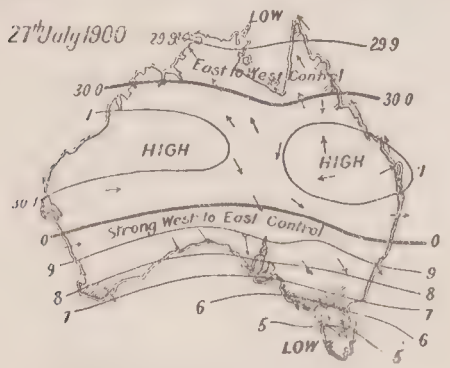
Australian climate, and very different from the conditions that obtain in India—where, if the monsoon season fails to bring rain, very little hope of relief can be looked for.

Any isobaric distribution that controls a strong wind-circulation from warm to cool areas, more especially from warm to cool latitudes, will bring about good rains, and the recurrence of such isobaric distributions is typical of good seasons. On the other hand, extensive isobaric distributions that control a wind-circulation



Isobaric distribution (wet type).

from cool to warm zones or latitudes, or that control a wind-circulation along parallels of latitude, will bring little or no rain except in



Isobaric distribution (dry type).

opposing coastal areas; these distributions predominate during, and are typical of, a dry season.

The normal distribution of rain in Australia has been ascertained from observations made over a minimum of 20 and a maximum of 50 years. During the hotter months (November to April inclusive) the northern parts of Australia are wet and the southern dry; during the colder months (May to October inclusive) the southern parts are wet and the northern dry. The rainfall is distributed fairly generally throughout the year over the eastern areas of Australia. During January and February fully three-fourths of the continent, comprising the whole of the northern and eastern areas, are wet; the central, southern, and south-western portions are distinctly dry. In March there is a general retreat northward of the rainfall area to the extent of 200 miles in Western Australia, a slight extension westward in the south-eastern quarter of the continent, and in Western Australia the 1-in. isohyetal appears on the extreme south-western coast. In April the northern rain area retreats in central Australia from the tropic to within 300 miles of the north coast, though still lagging over the north-western coast of Western Australia and the Murchison goldfields. In the south a decided westerly extension takes place from the south-eastern States to South Australia and Western Australia, the 1-in. isohyetal sweeping continuously round the southern shores with the exception of a short break at the head of the Great Bight. The northern rain entirely disappears in May, and the southern extends up the western coast of Western Australia to within a few miles of Cossack; quantities increase, as compared with those of the previous month, by 4 inches in the extreme south-western corner. June, the wettest month of the year for southern Australia, shows a complete reversal of January rain conditions. In Western Australia precipitation is general during this month west of a line joining Derby and Eyre, and in South Australia the 1-in. isohyet reaches its farthest northern limit in close proximity to Farina.

From July to December the rain area as a whole swings back in the opposite direction to its march during the first six months. On the western coast the 1-in. line steps back to Onslow in July; to Hamelin Pool in August; to Geraldton in September; still farther south in October; and all but disappears in the extreme south-west in November, so that little or nothing is left in December. While this retreat is taking place in the west, a corresponding advance is going on in the east. Between the end of June and the end of August there is little change, but from September to the end of the year the expansion of area and quantity of rain increase rapidly. October brings the return of monsoon rains in the Northern Territory; in November they have penetrated 450 miles farther into the interior and connected up with the permanent rain area over eastern Australia. In December monsoon rains cover practically the whole continent north of the tropic and east of the 144th meridian.

All this implies an oscillatory movement of the seasonal rains of Australia about a centre in the vicinity of Forbes in New South Wales.

Roughly speaking, June is the wettest month over that portion of Australia lying to the south of a line joining Onslow on the north-western coast of Western Australia and Sydney on the eastern coast. To the north of that line, January is the wettest month, although February runs it very closely over a wide belt of country extending from the lower Northern Territory through south-western Queensland to northern parts of New South Wales. March is the wettest month in parts of central Queensland, parts of central New South Wales, and over a comparatively small area on the north-western coast of Western Australia. At the junction of the summer and winter rains the wettest month is somewhat indeterminate. In New South Wales, for instance, every month with the exception of September is the wettest in some part or other—with a preponderance for June in the southern half, and January, February, and March in the northern half.

In *Western Australia* the heaviest rainfall occurs over the south-western portion of the State, which has a long coast-line exposed to the Indian Ocean and the full force of the westerly winds of southern latitudes. The rainfall there, and in fact over the south-western

half of the State except the eastern goldfields, is a winter one, 80 to 90 per cent of the annual totals, in the south-western agricultural areas, falling during the growing-period (April to October). From the coast for about 80 to 100 miles inland the rainfall decreases rather rapidly, but the area in the south-west over which 15 or more inches fall amounts to 80,135 square miles. The rapid increase from the western coast inland is partly accounted for by the range of hills which runs parallel to the coast from the extreme south to beyond the Murchison River, although they are not of sufficient elevation to serve as a natural store for precipitation in the form of snow. At some places on the southern area of these hills the annual rainfall exceeds 42 inches—about 10 more than on the coast. Inland, owing to the vast extent of land between the goldfields and the South Australian boundary over which the easterly winds pass, the evaporation is very great, amounting to about 87 inches annually at Coolgardie. On the coast, at Perth, it is 66 inches.

The full effects of the westerly winds of southern latitudes are apparently not felt beyond lat. 27½°, just reached by the 15-inch isohyet, and from there to the tropic the rainfall is scanty and occasionally amounts to only 3 or 4 inches in the year. From that isohyetal inland, towards the Murchison and North Coolgardie goldfields, though the records only extend back some 15 to 20 years, it is not likely that longer records will show much difference in the annual rainfall. The 10-in. isohyet skirts Yalgoo and Kalgoorlie and farther inland the average rainfall is below 10 inches, but those districts are subject at times to abnormal falls, as e.g. in March and April 1900, and January and February 1902, when Peak Hill registered 18.13 and 14.56 respectively, and Wiluna 22.82 and 9.69 inches.

North of the tropic, the Kimberley district receives good tropical rains during the summer months (November to March or April), but the De Grey and Fortescue districts are dependent for their rainfall partly on the tropical storms commencing about December, and partly on the winter rains from the Indian Ocean. The total amounts are smaller than those in the Kimberley district, and very variable; sometimes both tropical and southern winter rains fail, and at other times phenomenal falls occur during the 'willy willy' (or hurricane) season. Whim Creek registered 36.53 inches on three days in April in 1898.

The areas in Western Australia receiving varying quantities of rainfall, as shown on the map, are as follows:—

Rainfall.	Area in Square Miles.		
	Tropical, North of Tropic.	Remainder of Western Australia, South of Tropic.	Whole State.
Under 10 inches ...	52,368	434,584	486,952

,, 40 ,, 50 ,, ...	...	3,663	3,663
Over 50 inches ...	...	262	262
Total	352,879	623,041	975,920

The main factors which determine the rainfall distribution of *South Australia* are the proximity of the Southern Ocean and the long extent of coast-line exposed to the free and unrestricted sweep of the westerly winds nautically known as 'the roaring forties.' The rainfall over all coastal areas is essentially a winter one, and practically all available for agricultural purposes, as from 70 to 90 per cent of the total in the more settled areas falls during the growing-period (April to October). Though physiographic influence is less apparent than in south-eastern Australia, the effect of elevation is marked by the heavier rainfalls on the eastern sides of Spencer Gulf and the Gulf of St. Vincent, and by the northerly extension of the 10-inch isohyetal line from Port Augusta to beyond Beltana. The abundant rains on the Mount Lofty ranges, east of Adelaide, are a conspicuous example of this, the annual total on the crest of the range approximating to 50 inches. A rapid decrease takes place from the agricultural areas northwards to the interior, where in the Lake Eyre basin (which is below sea-level) the average annual fall—largely made up of capricious summer storms—is under 5 inches. This district is probably the driest part of the continent. In the Northern Territory the chief factor in the distribution of the rainfall, which is almost entirely confined to the six summer months, is latitude or distance from the north coast—the rains being abundant on the coast, but rapidly decreasing towards the interior.

The areas in South Australia and the Territory enjoying varying quantities of rainfall are as follows:—

Rainfall.	Area in Square Miles.	
	South Australia.	Northern Territory.
Under 10 inches	310,660	140,500
From 10 to 15 inches	36,460	132,780

,, 50 ,, 60 ,, ...	.....	25,456
Over 60 inches	.....	2,026
Total	380,070	523,620

The eastern littoral of *Queensland* from Cape York to the Tweed receives an annual average rainfall of about 60 inches. On parts of the north coast, between Cooktown and Townsville, this increases to 150 and 165 inches per annum. The main source of supply is the south-east trade wind, and local variations in totals are solely due to differences in elevations of the shore-line. On the peninsula the rainfall ranges from 68 inches at Cape York to 33 inches at Walsh River; in lower Carpentaria it averages from 16 to 39 inches. In the central districts the average varies from 30 inches on the eastern boundary to 17 inches on the western. In the Maranoa it averages about 23 inches, and over the Darling Downs from 25 to 30 inches. In the Warrego it varies from 15 to 20 inches, and in the far western districts from 15 inches down to 7 inches at Birdsville, in the extreme south-west corner. See MANDATED TERRITORY.

During the wettest months of the year (January to March) very heavy daily falls over the

eastern areas are not by any means infrequent. A fall of 10 inches and over in the 24 hours have been recorded on many occasions. On 2 February 1893 35.71 inches were measured at Crohamhurst on the Blackall Range; this constitutes one of the world's records for heavy rainfall. On that occasion the total measurement for the four days ending 3 February was 77.305 inches. The following table shows the areas in square miles of varying quantities of rainfall:—

Rainfall.	Area in Square Miles.
Under 10 inches	80,496
From 10 to 15 inches	81,549
,, 15 ,, 20 ,, ...	111,833
,, 20 ,, 25 ,, ...	143,610
,, 25 ,, 30 ,, ...	99,895

,, 50 ,, 60 ,, ...	25,286
,, 60 ,, 70 ,, ...	9,506
Over 70 inches	4,406
Total	670,500

In *New South Wales* nearly all the districts near the coastal rivers show a depressed rainfall in comparison with surrounding and naturally higher country. Starting from the northern border, the 50-in. isohyetal line at Casino on the Richmond River deviates slightly towards the sea-line; the same feature may be noted, in a more or less marked degree, on the Clarence, Macleay, Manning, Hunter, and Shoalhaven rivers. The Nepean valley can be traced right through from Picton to the Hawkesbury by its relatively light rainfall. On the northern tablelands the higher levels enjoy falls well over 30 inches. The extension of that isohyet encloses a narrow tongue-shaped area, reaching in a south-westerly direction from Inverell to Lindsay; the elevation of this area is higher than that of the country on its western and southern boundaries.

Farther south the effect of the Blue Mountains and the Canobolas is particularly conspicuous. The extension of the Australian Alps, which almost entirely feed the Murrumbidgee River and contribute largely to the constant flow of the Murray, stands out in clear relief. Although a considerable distance from the coast, the elevation is such as to modify the disadvantage resulting therefrom; and not only is abundant moisture extracted from the winds from the east coast, but considerable condensation takes place on the western aspect from south-western winter winds that have swept across nearly the whole of Victoria. The comparatively light rainfall in the district extending from Delegate to Yass (especially between Bobundra and Michelago) is one of the most remarkable features of the rainfall map. Although the greater part of this district is considerably over 2000 feet high, it is enclosed by ranges rising to 3000 and 5000 feet, which intercept moisture that would otherwise benefit it. Yet, although the falls over this area do not exceed 25 inches, it is remarkably productive; evaporation is relatively small, and a vast quantity of soakage must find its way there from the encompassing ranges. The Sydney and Burrinjuck water-supply catchment-areas receive annual totals ranging from 30 to 60, and from 20 to 60 inches respectively.

Areas in New South Wales enjoying varying quantities of rainfall are shown in the following table:—

Rainfall.	Area in Square Miles.
Under 10 inches	48,749

Over 70 inches	365
Total	310,372

In *Victoria* the abundant rains on the Australian Alps, the Cape Otway ranges, and the Gippsland ranges are particularly conspicuous. In a less striking manner is shown the precipitating effect of the central Dividing Range and the Grampians. The comparative lack of rainfall in the relatively depressed areas north and west of Melbourne is due to the effect of the higher surrounding country on rain-bearing winds. A similar effect is noticeable in the Latrobe, Thomson, Tambo, and Mitta Mitta valleys.

Areas in Victoria enjoying varying quantities of rainfall per annum are as follows:—

Rainfall.	Area in Square Miles.
From 10 to 15 inches	19,270
,, 15 ,, 20 ,, ...	13,492
,, 20 ,, 25 ,, ...	14,170

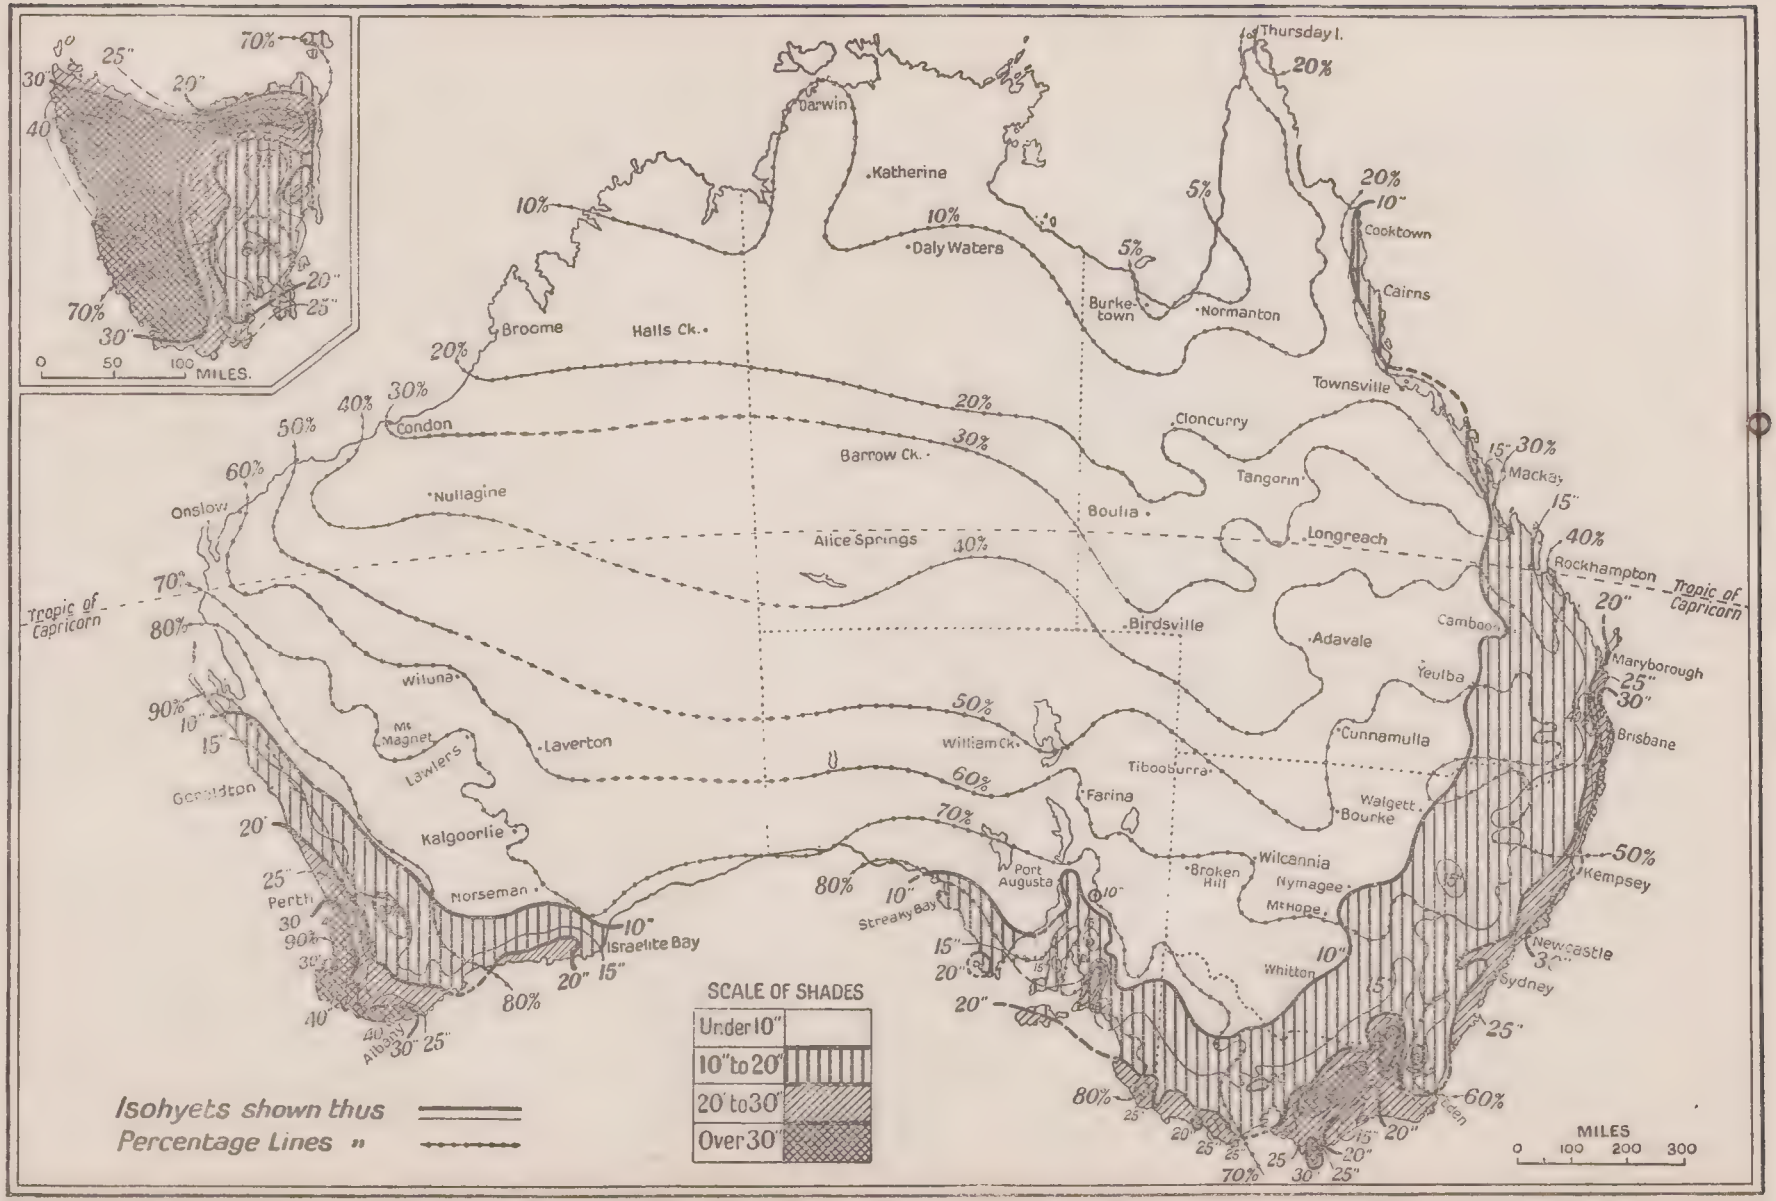
Waratah	117·24	59·97	86·50
Mount Read	145·04	70·38	110·45

The most striking feature in these parts of the island is the great variation shown for such a comparatively small area between the greatest and least average falls—from 17.93 inches at Beaufront near Ross to 116.92 at Mount Lyell on the west coast, showing a range of 98.99 inches. The west coast, being exposed to the full sweep of moisture-laden westerly winds—condensation being assisted by altitudes of between 3000 and 5000 feet—experiences frequent rains, and high annual averages, over 100 inches in places, are the result. The effect of altitude is again noticeable in the south-east, where Hobart, at an elevation of 160 feet, has an annual rainfall of 23.83 inches, while the



AVERAGE RAINFALL FOR THE WHEAT-GROWING PERIOD (APRIL TO OCTOBER).

adjacent Mount Wellington, at the 2500-ft. level, totals 59 inches.

The heavy rains experienced in the north-east are similar in character to those on the coast of New South Wales and eastern Victoria, and the south-east winds exercise a certain amount of control over the rainfall of this portion of the island.

Areas in Tasmania enjoying varying quantities of rainfall are as follows:—

Rainfall.	Area in Square Miles.
From 15 to 20 inches	304
„ 20 „ 25 „	3,844

Bruni Island has been included with the mainland.

Rainfall and Wheat-growing.—In Australia wheat-growing under ordinary conditions is generally considered payable when at least 10 inches of rain fall in and between April and October. There are approximately 484,330 square miles of country satisfying this condition, distributed as follows.—93,500 square miles in Western Australia, 46,980 in South Australia, 79,247 in Queensland, 163,772 in New South Wales, 74,616 in Victoria, and 26,215 in Tasmania. Much of the land, however (probably half the total), is unfit for wheat-growing by reason of excessive rains, early summer rain, topography, or soil; but as compensation large tracts of interior land may be brought under cultivation by the adoption of drought-resisting seed and dry-farming methods.

The boundary of the 10-in. wheat period isohyet starts on the western coast of Western Australia, a few miles south of Hamelin Pool, thence passes inland in a south-easterly direction towards Southern Cross, from there almost due east, entering the Great Bight to the north of Israelite Bay. It again enters the mainland between Fowler's Bay and Streaky Bay, in South Australia, curving south-eastwards from Yardea to Spencer Gulf to the north of Cowell, and crossing the gulf it strikes the peninsula near Port Pirie, forming a loop over the country well to the north of Port Augusta, whence it takes a sinuous course southwards through the lower Mallee to the north-east Wimmera, crossing the Murray River in a north-easterly direction to the west of Deniliquin in Riverina, then over the Murrumbidgee River at Darlington Point, from there bending northwards and passing successively near Mount Hope, Nymagee, Coonamble, Walgett, to Mungindi, whence it extends almost in a direct line northwards, finally leaving the Queensland coast at Bowen.

Barometric Pressure.—South of a line joining Perth and Brisbane the annual average pressure is 30 inches. To the north of that line it gradually diminishes to 29.8 near Cambridge Gulf, on the extreme north-western coast, and on the coast of the Northern Territory.

In January the average pressure over southern Australia varies from 29.8 to 29.95 and in northern Australia from 29.7 to 29.8 inches. In July south from the tropic the average is from 30.1 to 30.15, and north of it from 30.1 to 29.9. Over the northern half of the continent only one monthly maximum and minimum of pressure is noticeable—in July and January respectively—but over the southern half there are two minima which become increasingly marked as the south-east corner of the continent is approached. These minima occur in May and July. Throughout the year there is generally shown a concentration of pressure over the south-eastern quarter of the continent and the reverse in the north-western quarter.

Winds.—The most conspicuous winds of Australia are (*a*) the south-east trades, which blow almost continuously over the northern half of the continent, and (*b*) the westerly winds ('roaring forties') which during the winter months extend northwards over the whole of the southern areas. Both these winds, however, are strongly deflected by continental or monsoonal

influences—so much so that in summing up the average prevailing direction of wind in different parts of Australia, particularly over the southern portions, these two great systems of wind circulation are almost obscured.

On the southern coastal areas, for example, the average prevailing direction has a strong southerly component during the summer months, and a northerly component during the winter months; in the north of the continent a strong northerly component during the summer months and a southerly during winter months. On the New South Wales coast the mean direction in summer is from the north-east, and in winter from the west. On the Western Australian coast the mean direction during the summer months is from south-west to south-east, and during the winter from north-north-west to north-north-east. Inland the mean direction of wind is largely dominated by the seasonal distribution of pressure. Thus during the winter months, when anticyclones are constantly building up pressure in the interior, there is a decided spiral, contra-clockwise circulation from the centre towards the coast-line. During the summer time, owing to strong convectional action in the interior and consequently lowered pressure, the circulation is reversed, and a clockwise, spiral circulation obtains from the ocean to the centre of the continent. Additional minor factors of wind-control are occasional unusually energetic cyclones (chiefly on the eastern and north-western coast-lines), and tornadoes—which may occur in any part of Australia during the summer months, but are most frequent over inland areas. These tornadoes generally develop in extensive barometric col areas, or over zones where the pressure is uniform and without isobaric control, or in the north-eastern or northern gradients of cyclonic depressions moving across the southern interior of the continent—the gradients again being very slight. They generally travel on a north-north-west to south-south-east course, and at times are so strong as to level strips of country forest and destroy townships.

A north-east sea-breeze ('black north-easter') is a notable feature of Sydney weather. It starts to blow about 10 a.m. on bright summer mornings, gradually increasing in force until 3 p.m., when it often reaches a velocity of 30 or 40 miles per hour; from that hour it gradually moderates, and generally ceases with sundown. The depth of this wind is comparatively slight; it does not ordinarily penetrate inland more than 10-20 miles.

'Southerly busters' are a distinctive feature of summer weather on the coast of New South Wales, occurring most frequently between September and February inclusive, and between 7 p.m. and midnight. The wind comes suddenly from the southerly quarter, causing a fall in temperature of from 20 to 40 degrees in 24 hours; the most rapid decline takes place during the first hour of the blow. The mean velocity is about 32 miles per hour, and many gusts may reach a rate of 80 miles and over. Blows may last for a few hours only or for several days, the duration being dependent upon the extent of the anticyclone to the west. Thunderstorms frequently accompany the bursts, but useful rains occur only when the centres of the high pressure are travelling in high latitudes. The rate of translation of a 'buster' along the coast is about 20 miles per hour, and has no relation to the velocity of the prevailing wind. A mild burst may be translated at 60 miles per hour from point to point on the coast, whereas a violent burst may be translated at less than 20 miles per hour. 'Busters,' while undoubtedly deflected sea-breezes, occur generally with the passage of the axis of V-shaped depressions backed up by anticyclones to the west of them. The change of wind takes place from a northerly to a southerly component at the moment when the axis happens to coincide with or cross any point; but, as the axes of these depressions are constantly varying in their angular relation to the coast-line, it follows that the rate of translation must vary accordingly. If the axis takes the same angle as the coast-line, the burst occurs almost simultaneously on all parts of the coast. If the axis is vertical or runs from north-west to south-east, translation is from south to north; this is the general experience, but it has happened that the bursts have worked down the coast, owing to the axis of the depression on such rare occasions running from south-west to north-east.

Southerly winds of this kind are most frequent during seasons of sporadic rains in the interior, and least frequent during exceptionally rainy seasons in the interior—which is strong evidence that they are a response to intense heat-convectional action inland. They can always be looked for on hot days; but the most reliable attending indication is the proximity of a V depression, or relatively low barometers in comparison with those over Victoria. A foggy morning following a hot day is also a sure sign, and the local barometer invariably starts to rise slowly several hours before their advent. They now rarely arrive without ample warning. The average number of visitations in a season is 32; the greatest number (58) was recorded in 1896, and the least (16) in 1890, when vast areas in western New South Wales were under the flood-waters of the Darling River.

The term 'brickfielder,' now applied to hot, dusty northerly winds on the goldfields of Victoria, was the first name given to the 'southerly busters' in Sydney. Brickfields in the early days were worked to the south of the infant city, and with the arrival of southerlies clouds of dust from these fields were brought to the northern end of the town. Diggers from Sydney, migrating to the goldfields of Victoria half a century ago, transferred the name to the hot northerlies prevailing there.

The 'Fremantle doctor' is the local sea-breeze at the chief Western Australian port. It is a cool wind from the south-west, generally starting soon after midday during the summer months, and, of course, moderating with the declining sun.

'Cock-eye Bob' is the name given to thunder-squalls which occur frequently on the north-west coast of Western Australia during the summer months.

Hurricanes.—The two zones of Australia subject to hurricanes are the north-western coast of Western Australia and the northern coast of Queensland. The hurricanes on the former, known as 'willy willies,' are, perhaps, the more violent of the two. The storms occur between the months of November and April (inclusive), but more frequently during January and March. They appear to originate in the vicinity of Cambridge Gulf, or even as far east as Darwin. They then start on a parabolic course along the north-western coast-line, gradually intensifying until they reach the latitudes of Condon and Cossack, where they generally reach their greatest energy and cause considerable damage to the pearling-fleets as well as to property on shore.

From this position on the north-west coast they usually recurve inland, gradually expanding in dimensions, and, travelling through the Murchison and Coolgardie goldfields (where they precipitate at times torrential rains) finally pass into the Great Bight, thence following the course of the southern depressions. Whim Creek on the north-western coast has frequently received 10 inches of rain from these hurricanes. On 3 April 1898 29.41 inches were registered for the 24 hours, together with a fall of 7.08 on the previous day—a total of 36.49 inches within 48 hours.

The isobaric indications are a high-pressure system over subtropical areas, and an incipient low on the north-western coast. When local barometers show signs of falling with an easterly wind, conditions are conducive to the development or approach of 'willy willies,' and precautions should be taken accordingly. A rapid fall with increasing force of wind from the east may be regarded as a definite indication of a heavy blow. Divers affirm that 24 hours' notice is always given of the approach of these storms by a sub-oceanic swell, and mariners say that the sky assumes a pale-green aspect for a day or so before the hurricane arrives.

Hurricanes on the north-eastern coast occur most frequently between January and April, but occasionally may appear as late as June. They

WET SEASONS AND STORM SEASONS

begin generally in the South Seas in latitude 8° or 10° S., follow a parabolic course similar to that of the western hurricanes, and almost invariably strike the coast between 15° and 20° S. latitude, in which zone they exhibit their most violent phases. Occasionally, however, they first present themselves nearly as far south as Brisbane, travelling thence down the eastern coast as far as Sydney, finally passing off into the Tasman Sea. The rain from these hurricanes is in all cases very heavy on the coastal and highland areas over which their influence extends.

One of these hurricanes struck Port Douglas on 16 March 1911, killed two men, and practically destroyed the township, together with all the meteorological equipment, so that no local rain was recorded. At South Mossman, 8 miles distant, the total rain registered in 24 hours was 16.1 inches. During the passage of another cyclonic storm towards the end of the month, over 63 inches fell at the same place in five days, distributed as follows:—3.44 on the 30th; 9 on the 31st; 31.53 on 1 April; 13.74 on the 2nd; and 5.64 on the 3rd. During the fall of the 31.53 inches the following measurements were recorded:—8.28 inches in 7½ hours, 9.7 in 3 hours, 3.93 in 2 hours, and 9.62 in 11½ hours.

The 1918 hurricane-season—in which two storms struck and crossed the coast-line, causing an enormous amount of damage—was perhaps the most severe ever experienced in Queensland.

On 20-21 January a tropical storm crossed the coast in the vicinity of Mackay with disastrous results. Twenty lives were lost; many of the

buildings in Mackay were damaged or completely demolished; the bridge across the Pioneer River (connecting North and South Mackay) was wrecked, and several small steamers, lighters, and motor-boats were either wrecked or left stranded on shore. The cyclone was accompanied by a 'storm wave' of about four feet, which swept up the river on top of a high tide, and caused considerable damage by flooding. Barometric pressure fell to 27.55 inches. The heavy rain which almost always accompanies these storms was not experienced until immediately in front of the centre and during the passage of the rear half. No observations were taken at Mackay at 9 a.m. on the 21st, but between 9 p.m. on the 20th and 9 a.m. on the 22nd 2270 points were recorded. This was followed by 1725 points to 9 a.m. on the 23rd, 1361 to 9 a.m. on the 24th, and 68 points to 9 a.m. on the 25th, making a total of 5642 points (over 5½ feet) in 4½ days.

On the night of 10 March a tropical storm struck and crossed the coast-line in the neighbourhood of Flying Fish Point, and, travelling inland, wrecked or damaged almost every building in Innisfail. Other centres that suffered severely were Babinda, Cairns, and Herberton. From the seaboard to the Atherton tableland the tropical vegetation was torn and stripped almost bare of leaves and branches. Sixteen lives were lost. Barometric pressure fell to 27.88 inches. This storm was perhaps more severe than the Mackay cyclone, though the latter was of longer duration and accompanied by heavier rain. At Dunk Island, which lies in the Pacific 110 miles north of Townsville, about 60 miles south of Cairns, and 2½ miles off the Queensland coast, the cyclone of 10 March was severely felt, as the following extracts from E. J. Banfield's *Last Leaves from Dunk Island* (Sydney, 1925) will show:—

Ten days before the second storm, while the sky was cloudless and the air serene, a change in the quality of the heat was felt. During the first three months of the year—the period of heavy rainfall—the temperature is generally humid. Suddenly it became dry and burning, with a tingling intensity, as rare as uncomfortable. For the time the moist vapours of a mild steam-bath were dispersed by scorching breath as from a furnace, to the discomfort of animal life and the injury of vegetation.

Early on the morning of Sunday, 10th March, the sky became overcast. A fresh southerly breeze had sprung up during the night. A short, confused sea tumbled in the channel, and the usually placid bay mimicked its sport. . . . The wind developed as it veered to the east. At 5 p.m. it was travelling at furious speed, twisting branches from trees and thickening the now gloomy skies with leaves. Consistently with the strength of the wind the barometer fell until between 9 and 10 p.m., when, with a conglomeration of terrifying sounds varying from falsetto shrieks to thunderous roars, the centre of the cyclone seemed to bore down on the very vitals of the island.

The devastating assault lasted about half an hour; it was followed by a lull, succeeded by another attack of violence from the north and north-west; then, as orderly as the storm had developed, so it subsided.

The following are the readings of the barometer during the day:—

9 a.m.	29.90	5 p.m.	29.50
Noon	29.40	6 p.m.	29.60
3 p.m.	29.70	7 p.m.	29.30
4 p.m.	29.60	8 p.m.	29.18

As the 8 p.m. observation was taken, the unassisted finger dropped 2-100ths with a jerk, and within a few minutes the demons of the air were crazy with fury. That was the final reading for the night, for the crisis came with such ferocity that the wreckage of parts of the house made the site of the instrument inaccessible; nor was it possible to consult it again until shortly before nine o'clock the following morning, when it stood exactly at the point from which it had begun to move twenty-four hours before.

Only while the core of the storm was passing was lightning seen or thunder heard. Then the whole mass of tumultuously-racing clouds and vapour was luminous at frequent intervals, and the rumble of the thunder almost continuous. . . .

Throughout the night rain was incessant; but its torrential tramplings on the resonant, ceilingless roof were not to be detached from the discordancies of wind and wave, save only while breath was held in expectation of whatsoever might happen after the terrifying lull. The gauge overflowed at 10.50 in., so that the exact quantity for the twenty-four hours during which all ordinary concerns and interests were wafted aside cannot be stated; but, by comparison with results of previously recorded deluges, the fall must have exceeded 14 in., the greater volume of which should be ascribed to about five hours.

Being in perfect sympathy with each other's fury, wind, rain and sea, in a common tongue, spoke threats of ruin and devastation, and fulfilled them all in more or less degree. . . .

While the rage lasted, a slight degree of comfort was attained from considering the suddenness of the storm and its very violence. At its lowest the barometer indicated nothing out of the normal; but its marvellous activity as the wind gathered in force, the sensational drop immediately prior to the crisis, the recovery as the depression passed over, and the subsequently revealed fact that the course of the storm was brief—little over a hundred miles—show that it was home-brewed. Subsequent information proved that the dangerous phase was not experienced for more than twenty miles to the south and twenty-four miles to the south-west.

The admiralty hydrographic office in 1897 published the following remarks and advice concerning tropical hurricanes on the Queensland coast:—

Tropical hurricanes on the coast of Queensland may be expected during the summer months, namely, December, January, February, March, and the early part of April. These storms appear to originate between latitudes 8° to 12° S., and between the meridians of 155° E. and 170° W. On reaching the Queensland coast they may strike the land at any point between latitudes 12° and 26°—that is, between Cape Grenville and Wide Bay. To the southward of latitude 26° S. these storms break up into heavy gales. If, during the summer months, and the early part of April, a heavy swell sets in from north-east, and there is little or no wind at the time, bad weather is certain, for the sea always is in advance of a cyclone. With the glass steadily falling, heavy rains, and murky sky, winds between south-south-east and east a cyclone may be expected. These storms may extend some distance inland, but their centres do not often pass the coastal ranges, which appear to repel them, and they usually emerge from the coast between Broad Sound and Cape Moreton. If the barometer is high over a considerable portion of the coast, the storm will recurve some distance off the land, and the wind will be from south-east to south. If, on the contrary, the barometer is low in front of the storm, it will blow home on the land as far as the coast range, and cause floods. When this happens the first of the gale will be southerly, the latter part northerly. The bearing of the storm centre will be at right angles with the waves line. Thus, on a fine day if there is a heavier sea than usual breaking on the beach, and it is coming from the north-east, if the direction remains the same or nearly so, and the barometer is not above 30 inches, the gale will blow home on the land, and the first signs of bad weather will not precede the gale by more than 12 hours, but if the direction of the swell

changes to the eastward the storm is recurving, and the body of it will not reach the land. When the swell is from the east the storm centre is past; when there is anything southing in the line of the swell the storm has passed. No matter how threatening the weather signs may be, if the line of swell comes first from the southward, there will be only an ordinary south polar storm, with a low temperature.

H.A.H.

Methodist Church, The. The introduction of Methodism as an organized body into Australia dates from the evening of 6 March 1812, when a few laymen met in the house of Thomas Bowden in 'the Rocks' area at Sydney for the purpose of Christian fellowship. On 3 April, at a similar gathering (known in Methodist phraseology as a class-meeting), it was decided to request the Wesleyan Missionary Society in London to send a missionary to Sydney; Thomas Bowden and John Hosking, the leaders of the classes, signed the appeal on behalf of the society, and promised that, if a missionary were sent, he should be no further charge upon the society in London—a promise they were unable to fulfil. These leaders were subsequently joined by Edward Eagar, James Scott, and John Lees. Scott bought two allotments of land in Princes-street, and on one built a chapel at his own expense at a cost of 500 guineas. This, the first Methodist chapel in Sydney, he presented to the mission; it was opened on 17 March 1819, Walter Lawry (q.v.) being the preacher. Hosking (whose son became the first mayor of Sydney) came to the settlement through Marsden's influence in or about 1809 to take charge of the girls' orphan school established in August 1801 by Governor King. Eagar, an Irish attorney, had been visited by Methodists when he was under sentence of death for embezzlement; the death-sentence was commuted for transportation, and Eagar, when his sentence expired, settled at Windsor as preacher and teacher. He afterwards received an unconditional pardon from Macquarie in January 1818, entered into business in O'Connell-street, Sydney, and accompanied William Redfern to England in 1821 to plead the cause of the emancipists. Bowden, who reached Sydney on 28 January 1812, organized the boys' orphan school and taught there for some years. Lees was a private in the New South Wales Corps (q.v.); when it was disbanded he settled at Castlereagh, and built a chapel of rough slabs at his own expense, presenting the building and 3½ acres of land to the society in Sydney. This was the first Methodist chapel in the southern world. It was opened by Samuel Leigh on 7 October 1817.

The 'historic appeal' of 3 April 1812 was answered by the appointment of Samuel Leigh (q.v.), who arrived in Sydney on 10 August 1815, and preached his first sermon in Scott's house in Gloucester-street. On the next day Eagar introduced him to Governor Macquarie, from whom he received promises of support that were generously and faithfully fulfilled. Leigh and his co-workers rented a house in Gloucester-street at £15 per annum; this they adapted for divine worship, and Leigh preached in it every Sabbath day at 6 a.m. and 6 p.m. until the Princes-street chapel was opened—the hours being chosen to avoid interference with services conducted by the Anglican chaplain. When Leigh had organized the Church in Sydney he visited Castlereagh, Parramatta, the Hawkesbury River district, and Liverpool, preaching at each station and arranging for regular services where possible. In 1818 he was joined by Walter Lawry (q.v.) and in 1820 by Ralph Mansfield (q.v.) and Benjamin Carvosso (q.v.). In 1821 Lawry built the first chapel in Macquarie-street, Parramatta, largely at his own expense. To Newcastle Leigh went first in response to a request from the Anglican chaplain Cowper, and a second time through Macquarie's influence, preaching on both occasions in the church erected by the governor. Joseph Orton preached first at West Maitland (which he termed Hunter's River) in 1839; but Methodism had previously been introduced into that district by Jeremiah Ledsam, a lay preacher from Ireland. In 1832 Orton visited the Bathurst district, and conducted divine worship in the home of one Lane at Tarana, at Terry's farm, in William Lane's barn at Bathurst, and in the home of William Tom at Springfield. At Goulburn Matthew Trenery, John Wheatley, and John Simpson established services in 1842. To New England, the Riverina, the Richmond River, and the South Coast Methodism found its way later.

Tasmania.—In 1817 Leigh suggested to the Wesleyan missionary committee in London that a missionary be appointed to Tasmania, and Carvosso on his way to Sydney visited Hobart on 25 April 1820, and asked the governor's permission to hold an open-air service. Sorell referred him to the Anglican chaplain, Robert Knopwood, who welcomed him warmly and ordered the constable to accompany him to the service. Standing on the steps of the court-house with his wife, Carvosso preached to 100 people. In the following October Corporal George Waddy and two other Methodist soldiers were sent to Hobart. At the house of Benjamin Nokes in Collins-street they held their first class-meeting on 29 October, Nokes being the leader; a few days later they removed to the house of one Wallis in Liverpool-street, where services were held until better accommodation was found in the shed of a man known locally as Charles Donn—this was in Argyle-street, on the site occupied by the Bird-in-hand hotel between Liverpool- and Collins-street. Donn, whose real name was Cranmer, claimed to be a descendant of the archbishop. A Sabbath-school of 23 scholars, commenced on 13 May, was the first Sabbath-school in Tasmania. Nokes and one Butcher visited New Norfolk, where they held a service in the house of one Albe and proposed a plan for the building of a chapel. Corporal Waddy, who had been sent from Sydney to Macquarie Harbour, succeeded in starting a class-meeting there. In 1821, when Samuel Leigh, then general superintendent of missions, was returning from England, he called at Hobart on 8 August, accompanied by William Horton. Horton was left at Hobart where he began the erection of a church in Melville-street on land given by David Lord. Nathaniel Turner came to Horton's help for 12 months, Mansfield succeeded him in 1823, and in 1825 Carvosso took Mansfield's place, and completed the building of Horton's church. In 1822 John Hutchinson was sent from Sydney to Launceston, and in 1827 William Schofield (q.v.) was stationed at Macquarie Harbour with very beneficial results. John A. Manton, G. A. Robinson (q.v.), Captain Horton, John Leach, Frances French, and others assisted in establishing Tasmanian Methodism, and in 1835 Tasmania was constituted a separate district with Joseph Orton as chairman.

Victoria.—In 1836 Orton visited Port Phillip,

accompanied by John Batman, who had been a scholar in the Wesleyan Sunday-school at Parramatta. On 24 April Orton conducted the first religious service in Victoria, standing on the eastern slope of Batman's Hill. The liturgy was read, the responses given by the resident magistrate, James Simpson, and the singing led by Alexander Thompson, afterwards mayor of Geelong. Orton afterwards selected 64,000 acres at the head of Corio Bay for an aboriginal mission-station, later known as Buntingdale. Subsequently George Lilly, J. J. Peers, W. Witton, and others formed a fellowship meeting (with Witton as leader) in a house in Lonsdale-street, the first Sunday-school was held in Russell-street, and in 1838 the first chapel was built at the corner of Swanston-street and Flinders-lane. Benjamin Hurst and Francis Tuckfield, who were in charge of the Buntingdale station, preached in Melbourne once a month, the pulpit being filled on other occasions by E. S. Parker and James Dredge, assistant-protectors of the aborigines. Orton made a second visit in 1839, and in November of that year William Simpson of Launceston induced the Melbourne Methodists to secure a site at Eastern Hill, which was afterwards exchanged for half an acre at the corner of Collins- and Queen-street. In 1840 Orton took temporary charge of the work at Melbourne, finding on his arrival (3 October) 80 Church members and seven lay preachers, and held his first quarterly meeting in Russell-street on 28 January 1841. Samuel Wilkinson, the first resident minister, took up his residence in April 1841. The Collins-street chapel was opened that same year, the preachers being W. Waterfield, Orton, Tuckfield, and Forbes. New chapels were determined on at Fitzroy and Brunswick, and in 1842 James Dredge was sent to Geelong to superintend the work there. William Schofield was appointed to Melbourne in 1842, being succeeded by Edward Sweetman in 1845 and William Lowe in 1847; in the same year John Christian Symons and Robert C. Flockhart were accepted as the first local candidates for the ministry.

The Primitive Methodists date their foundation from 1849, when John Ride was appointed to Melbourne and erected a church at the corner of Lygon- and Latrobe-street. The first district synod was held on 9 September 1851 under the chairmanship of William Butters. The discovery of gold brought to Victoria many Methodists, who assisted vigorously in developing and extending the Church and its agencies.

South Australia.—Methodism in South Australia is coeval with the foundation of the settlement. Captain Morgan of the *Duke of York* (which brought out settlers) and Samuel Stephens, manager of the South Australian Company, were Methodists. The Methodists who arrived at Kangaroo Island and Holdfast Bay held their meetings in the manager's house and in a carpenter's shop; when a move was made to the present site of Adelaide, they met in scattered tents known as Buffalo Row, until Edward Stephens, brother of the first manager, placed first a storeroom and then a kitchen at their disposal. In the kitchen on 11 May 1837 a society was formed with two classes under the leadership of John C. White and Jacob Abbott. Thenceforward public services, prayer-meetings, and a Sunday-school were held regularly. A site for a chapel was selected in Hindley-street, where a roofless church was opened on 13 March 1838; the absence of a roof (through lack of roof-timbers) was made up for by the use of tarpaulins. The appointment of a missionary was next sought, and made unexpectedly; on 21 June the *Fanny* was wrecked on the Coorong beach (between the Murray mouth and Lacepede Bay), with William Longbottom (q.v.) and his wife and child on board, bound for Western Australia. Longbottom reached Adelaide on 17 August, where he was joyfully received and took charge of the infant church. A second church was built in Gawler-place, the foundation being laid by Sir George Gawler on 7 November 1838, and the opening effected on 7 July 1839. Longbottom the Methodist, J. Drummond the Presbyterian, and T. Q. Stow the Congregationalist preached at the opening. In 1840 Longbottom was succeeded by J. Eggleston, and he by John Weatherstone in 1842. John Wiltshire, a Primitive Methodist, conducted the first service in connection with that body in Light-square on a Sunday afternoon in June 1840.

The Bible Christian Church originated at Kapunda and Burra Burra, whither several Methodist immigrants and lay preachers had found their way. Their request to the English conference for ministers was responded to by the appointment of James Way and James Rowe.

Methodism in *Western Australia* also synchronizes with the foundation of the colony. The *Tranby*, one of the first vessels to reach Fremantle, was chartered by two Wesleyan Methodist families, the Hardeys and the Clarksons, who had with them several other Methodists, including G. Johnson. Soon after the arrival of the *Tranby* in February 1830, the first Methodist service in the colony was held 'amid a babel of noise and confusion.' Religious meetings were established at Peninsula Reserve, Joseph Hardey acting as leader. Meetings were also held at Perth and Guildford—Perth finally becoming the centre; divine worship was held there in the open air under a jarrah-tree in Hay-street. When a class-meeting was organized, James Inkpen was appointed leader. In January 1833 George Shenton and Charles and Bernard Clarkson joined them, and a meeting was held at Perth on 22 January 1834, when it was determined to erect a chapel. A site facing Murray-street was purchased from Inkpen for £5, and the church was opened on 22 June 1834, Joseph Hardey being the preacher. A Sabbath-school was commenced under the superintendency of Inkpen, and Joseph Hardey, J. W. Hardey, G. Lazenby, H. Trigg, and B. Clarkson, all lay preachers, were responsible for the services until the arrival in June 1840 of John Smithies, who remained in Western Australia until 1855. Smithies held service in the court-house at Fremantle on 19 July and on 9 September 1840

In *Queensland* the beginnings of Methodism are not traceable. Among the soldiers were some Methodists, Corporal Fursman being the only one whose name is remembered. In 1847 William Moore of Windsor, who was waiting for his commission as a missionary to Fiji, was sent to Moreton Bay, and commenced services in Queen-street near the present offices of the *Telegraph*. Land was obtained from the government in Albert- and Adelaide-street, and a church opened in 1849. Moore, who also commenced services at Ipswich, was succeeded by W. Lightbody, John Watsford, and J. G. Millard. A church was built at Albert-street, Brisbane, in 1856, and another at Ipswich in 1858; the present Albert-street church was built in 188′

Statistics presented to the last Methodist general conference, held at Brisbane in 1926, show: —ministers, 1116, 132 of whom are natives; home missionaries, 152; lay preachers, 8036; attendants on public worship, 606,117; Sabbath-schools, 3511 (1206 native); Sabbath-school teachers, 30,196; Sabbath-school scholars, 203,431; theological institutions, 5; theological students, 71; book depots, 5; churches, 3752; schoolrooms, 990; parsonages, 769; colleges, 16. The census of 1921 gave the number of Methodist adherents in Australia as 632,621—12.01 per cent of the population.

The first district synod was held in Sydney in 1826, under the superintendency of George Erskine. This district synod was the chief Australian centre of authority until 1855, when the first Australasian conference met under the presidency of W. B. Boyce. In 1874 this conference was divided, and colonial conferences established, with a general or federal conference meeting every three or four years. The first such general conference held after the union of all the branches of the Methodist Church met at Melbourne in 1904, under the presidency of William Henry Fitchett.

The foreign mission work which is one of Methodism's chief glories is described under MISSIONS. Home mission work has been equally successful. Reports submitted to the general conference of 1926 show that in New South Wales there were 15 agents employed and (largely through the depletion caused by the war) many stations in which home missionaries were needed; the income for the year was £10,745. In Victoria there were 76 home missionaries, 44 of whom were married; the income raised in advance was £25,940. South Australia employs 26 home missionaries, and its income is £6296; in Queensland home missionaries averaged 20 and an income of £3059; in Western Australia the income was £2156. The work of the home mission societies extends beyond the appointment of home mission agents. In New South Wales the society administers missions to the far west, the north-west, and the Riverina districts, loan-funds to assist in the erection of churches, parsonages, and schools, the Vickery settlement fund, and the James Woolnough sites fund. In Victoria the society employs qualified lay evangelists and a colporteur, appoints chaplains to the hospitals and gaols, superintends the immigration movement, and assists mission work in Western Australia by a monetary grant. In South Australia the society is responsible for work among the soldiers and at construction camps in the Murray valley and the Eyre peninsula; it also deals with immigration and group-nomination. In Queensland and Western Australia the societies work among the soldiers' settlements. Nearly all the states have sisterhoods, children's homes, and homes for the aged, and New South Wales has a worthy war memorial in the form of a hospital at Waverley. Central missions, found in each capital city of the Commonwealth, are not under the jurisdiction of the home mission societies.

In the earliest stages of Australian Methodism it was not possible to do much for higher education, but, since the problems of pioneer settlement have to some extent been overcome, educational work is receiving greater attention. Colleges affiliated to universities (q.v.), theological halls, and schools for boys and girls have been established. Wesley College at Sydney, Queen's College at Melbourne, and King's College at Brisbane, are the three affiliated colleges. Wesley College with an average of 40 students for 1924-5-6, erected at a cost of £40,000, is free of debt, as is Queen's College (121 students), a magnificent structure erected at great cost largely through the inspiration of its master, Dr. Sugden. King's College works in conjunction with the Presbyterian and Congregational churches. In New South Wales and South Australia independent colleges have been established for training theological students. Boys' schools include Newington College at Sydney, Wallaroi College at Orange, Wesley College at Melbourne, Prince Alfred College at Adelaide, Wesley College at Perth, and schools at Brisbane and Charters Towers; the two last-named have been recently established under the joint management of Methodists and Presbyterians. Girls' schools are more numerous; there are four in New South Wales, one at Melbourne, one at Launceston in Tasmania, one at Adelaide, one at Claremont in Western Australia, and in Queensland at Brisbane and Charters Towers, under the Presbyterian and Methodist Schools Association.

The figures given above have been taken from the general conference minutes of 1926—the last available official source—and therefore refer to the year 1925.

Michael, JAMES LIONEL (1824-1868), born in London in 1824, practised law with his father, who was a solicitor, but found literature more congenial and spent his leisure hours in association with the pre-Raphaelite brotherhood. In 1853 the gold-fever brought him to Australia, but he soon found the diggings less remunerative than law, and before the end of the year was practising in Sydney. In 1857 he published *Songs Without Music*, a small volume of imitative but graceful verses; in 1860 appeared *John Cumberland*, an autobiographical sketch in verse. His best service to Australia was his encouragement of Henry Kendall (q.v.), whom he took into his Sydney office about 1858 and kept with him for a short time after moving to Grafton in 1861. On 28 April 1868 Michael was found drowned in the Clarence River.

Michie, SIR ARCHIBALD (1813-1899), born at Winchester in 1813 and educated at Winchester School, studied law and was called to the bar at the Middle Temple on 4 May 1838. Migrating next year to Sydney and being admitted to the local bar in November, he settled down to practise his profession, combining with it a good deal of journalism and joining Robert Lowe in the control of the *Atlas*; in 1848 he was elected first chairman of the Australian Mutual Provident Society. After a visit to England he returned to Australia in 1852 to settle in Melbourne, where he became a nominee member of council, dropped politics to own the *Herald* (then a morning paper), and lost heavily in the enterprise, but made his reputation by a successful defence of the Eureka rioters in 1855. From 1856 to 1872 he was a prominent figure in Victorian politics, representing Melbourne (1856-9), St. Kilda (1859-61), Polwarth

(1863-6), St. Kilda again (1866-8), and South Gippsland (1868-71) in the assembly, and sitting in the council during 1871-2. He was attorney-general in the Haines ministry of 1857-8, minister of justice in the first McCulloch ministry (1863-6), attorney-general in the third McCulloch ministry (1870-1), and in 1873 was appointed agent-general. This post he held until 1879, when he returned to Melbourne, retired from politics, and died on 21 June 1899.

Though a man of great culture and brilliance, his actual political achievement was small. In 1857 he interested himself in federation and in the problem of state education; but in after years he seems to have contented himself with influencing unobtrusively the cabinets and parliaments of which he was a member. (K.C.M.G., 1878.)

Migration. This article should be read in conjunction with IMMIGRATION RESTRICTION. On 10 July 1788 Governor Phillip begged the colonial office to send out free settlers, who would find employment for the convicts on farms, etc. In the 'additional instructions' issued to him on 20 August 1789 provision was made for the reception of migrants, who were to be given a free grant of land. On 16 January 1793 the first group of free settlers (eleven in all, including five adult males, being all who had so far offered themselves) arrived in the *Bellona*. They received a free passage, free grants of land, tools from the public stores, free sustenance for two years, and convict servants for whom the government undertook to provide two years' rations and one year's clothing. The land-grants—80 acres for married and 60 for single men—were located south of Homebush and Strathfield, the district becoming known as Liberty Plains. Other small groups followed, including one of Presbyterians from the Scottish border who arrived in 1802 and settled near Portland Head on the Hawkesbury. Macquarie, on taking office, objected to free immigration—especially that of 'gentlemen-settlers,' armed with letters from the colonial office, who 'imagine they have done H.M. Government so very great a favour by coming to New South Wales that no expense on the part of the Crown can repay the obligation, and the many great donations they receive from the Crown meet with no other return than discontent and ingratitude.' More objectionable still was the colonial office's habit of permitting applicants to send troublesome relatives to the colony, some of whom immediately sold their land-grant. Macquarie urged a limitation of the number of free settlers, and on his own responsibility inserted residence or cultivation clauses in the deeds of grant. His representations were favourably received, and on 3 February 1814 he was informed that great care was being taken that settlers should have sufficient capital for the cultivation of land, as well as testimonials from persons of known respectability. For those who had relatives in the colony the conditions were less stringent. Migrants were to be notified that they would only be entitled to draw free rations for six months. Later, it was decided to give no more free passages; on rare occasions settlers were permitted to travel in transports, but they had to pay for their provisions.

On 16 May 1818 Macquarie asked that no settlers should be allowed to come out who did not possess a capital of £500; experience showed that poorer settlers were unable to cultivate their grants, and drifted to the town. This request also was granted. In 1820, out of a total mainland population of 23,939 only 1307 had arrived as free settlers; for Tasmania the figures were 714 out of 5468. But the pressure of events could not be withstood. Despite the distress caused by the Napoleonic wars, the population of Great Britain had increased by 15 per cent between 1811 and 1821, and remedies for overpopulation were freely discussed. Numerous small capitalists applied in 1821 for admission to New South Wales, and especially to Tasmania, which had been highly spoken of as an agricultural country. So difficult did Macquarie find it to supply new settlers with land that a scale of land-grants proportioned to available capital was drawn up; the minimum capital required was £500. The practice of distributing free rations for six months still obtained, and cattle from the government herds were allotted to each settler, to be repaid in kind in seven years; but later in the twenties, as the stream of immigration broadened, these indulgences were discontinued. The number of free migrants to New South Wales and Tasmania during the twenties was:—1821, 320; 1822, 875; 1823, 543; 1824, 780; 1825, 485; 1826, 903; 1827, 715; 1828, 1056.

With the development of the pastoral industry the demand for assigned convicts exceeded the supply, and pastoralists experimented with the introduction of labourers under indentures for a term of years, but without much success. Distress in England and colonial labour requirements thus facilitated the adoption of Edward Gibbon Wakefield's proposals that colonial waste-lands should be sold at a 'sufficient price' and the proceeds used to promote the migration of labourers. On 14 February 1831 instructions were issued by the colonial office that henceforth lands must be sold, not alienated by grant, and a land fund created with the money thus obtained. On 24 June a board of commissioners was appointed in London to collect information for the use of migrants; at first no funds for emigration schemes were granted by the treasury, but the board might receive money from parishes for effecting the emigration of their paupers. On 28 September Bourke was informed that arrangements had been made to assist females to migrate to New South Wales, it being desirable to increase the proportion of females there; £10,000 was set aside towards the passage of unmarried females, preference being given to those migrating with families and to domestics suitable for employment in a farmer's family. Early in 1832 the first ship under this scheme was despatched, the women being chiefly from charitable institutions in Dublin and Cork. Meanwhile the commissioners had received many applications from persons—chiefly mechanics with families—willing to migrate, provided that the government made advances to be repaid from their earnings; the commissioners favoured this, recommending that families be granted a loan of £20 each family towards their passage, and the scheme was put into operation and was later extended to agricultural labourers. In 1835 the government undertook to pay for the full passage of female migrants, and converted the advances already made to labouring families into grants.

In New South Wales and Tasmania there was considerable discontent with the type sent out.

After functioning for a year, the emigration commissioners had resigned; their work was taken over by the colonial office, which relegated the task of selecting females to a voluntary committee of philanthropists. The actual selection was done by shipping agents, who wished to fill up the ships quickly; the result was unsatisfactory, and in 1834 Bourke suggested that a salaried officer should be appointed to supervise applications in England, and one was appointed at the beginning of 1835. Until 1833 the selection of mechanics and agricultural labourers had been left to the shipping companies; in that year a government agent was stationed at Liverpool, where most of the migrants embarked. The results, however, were still unsatisfactory, so in 1836 New South Wales (Tasmania was obliged to retard the rate of immigration) sent three naval surgeons to the United Kingdom to select and escort applicants to the colony. No females were to be accepted unless they belonged to, or accompanied, a family group; the men, preferably under 30 years of age and married, were to be one-third agricultural labourers and overseers, two-thirds mechanics. This method of selection was found expensive, and T. F. Elliott was appointed by the colonial office to exercise a general superintendence; early in 1838 he assumed full responsibility for assisted migration to New South Wales. In January 1840 a board of commissioners took over Elliott's work and also that of the South Australian commissioners (see SOUTH AUSTRALIA), since there had been an 'unseemly and injurious competition' between them. The board controlled the sale of crown lands and used the proceeds (except what was required for pressing local needs) to finance emigration.

The government system of selection had been severely criticized in New South Wales both on the ground of expense and because families with young children were brought out instead of single men willing to take up-country work; it was therefore decided, as a second and concurrent system of migration, to give to any private person who brought out married mechanics, or farm-servants under 30 years of age, a bounty of £30 per couple and proportionate allowances for children. A bounty was also payable on each unmarried female between 15 and 30 travelling with a family, and on single men, provided a like number of females were introduced. The bounties did not cover the full cost of passage, and were payable only if the migrants were approved by a special board on arrival. It was anticipated that employers under this scheme would secure the type of employees they required at a reduced cost to the public funds. Bounty migration, however, became a commercial speculation for shipowners, and liable to great abuses; nevertheless in 1839, when it was known that transportation was to cease, the legislative council of New South Wales recommended that bounties be increased to cover the whole cost of passage; this was done from March 1840, and during that year the government found itself pledged to pay about £979,600 on the arrival within two years of 71,315 migrants. During 1841 Gipps continued to issue orders, stipulating that the payment of bounties would be contingent on the state of the colony's finances; he apprehended no great inconvenience could result, since there was probably not enough shipping available to bring so many migrants to the colony; but the commissioners, alarmed by the increasing departures of bounty migrants from the United Kingdom, decided to suspend government emigration. To minimize abuses in the bounty system they undertook a supervisory control from January 1841, migrants and vessels being inspected, and a certificate issued to the master when all conditions had been complied with. Gipps appealed to the colonial office to check migration, and orders were issued that no bounty should be paid after November 1841. The bounty system was thus also suspended, although about 20,000 permits were still outstanding.

During 1840-1 there was a bitter controversy as to the respective merits of the two systems. The colonists said that the government system of selection was used to get rid of workhouse inmates and other persons of no value as settlers; the commissioners pointed out that these allegedly valueless migrants were readily engaged in good positions. In December 1839 a committee of the New South Wales legislative council reported that the bounty system was 21 per cent cheaper than the selection system. This report, however, was made before the bounties were increased. The mortality in government ships was less than in those under the bounty system, and on arrival government migrants were housed in barracks, and fed until they found employment; on the other hand, the practice of disembarking bounty migrants without making provision to house them temporarily—which obtained until 1840, when ten days on shipboard were allowed—led to serious hardships. Indeed, had it not been for the work of Caroline Chisholm (q.v.), the rush of bounty migrants in 1840-1 would have resulted in the stranding of large numbers of deserving people.

The Australian waste lands act of 1842 laid down the principle that the cost of survey, management, and sale of land should be a first charge on the land-fund, and that the remainder should be divided into two equal parts, of which one was to be devoted to migration. When needed, additional funds were raised by the issue of debentures. Under these provisions the colonial office in September 1843 decided that migration to New South Wales might be resumed on a small scale under a modified bounty system—bounty tickets to be issued in London for a specified number of migrants, for whom shipping contractors must provide passages through the colonial office. The commissioners undertook to inspect the ships and to protect migrants from fraudulent practices, but the risk of selection was left with the contractor, as bounties were not payable unless the migrants were approved either at Port Phillip or Sydney.

Towards the end of 1843 Gipps wrote that the colony could not then absorb many more migrants, and in July 1844, when 2614 had been sent out under the new arrangements, it was decided to postpone such other agreements as had been entered into. Recruiting ceased in 1845, and in 1846-7 no one arrived at government expense.

There had been much discontent at the proportion of Irish sent out under the bounty regulations; between January 1841 and June 1842 the proportion had been over 60 per cent. The commissioners explained that religion was not taken into account by them, and that the Irish offered more freely than others. At the instance of Dr. Lang (q.v.) a committee of the N.S.W. legislative council suggested in

1845 that 'whatever number of emigrants may henceforth be introduced ought to be derived in equal proportions from the three kingdoms.' Lang determined to counteract the Irish influence in the colony by the introduction of Scottish families into the Port Phillip and Moreton Bay districts. For the results of his scheme see LANG, JOHN DUNMORE, and COTTON.

Free migration was revived in 1848, but in the following year the commissioners reverted to the earlier system of assistance, a minimum charge of £2 being made for farm-hands and domestics, £5 for mechanics, and £7 for labourers; friends in the colony were permitted to nominate on payment of the minimum charges. Buyers of land who required labourers were permitted to nominate prospective employees. In certain cases bounties were allowed on Europeans introduced for special purposes, e.g. vine-culture. Private societies assisted individuals and groups to reach the colony, and the Family Colonization Loan Society (see CHISHOLM, CAROLINE) assisted families which were permitted to travel in the commissioners' ships; young women and girls from workhouses and boys and girls from ragged schools were helped by poor-law authorities and charitable institutions. Special provision for the reception of migrants was made in 1848, depots being prepared at Sydney, Melbourne, Parramatta, Goulburn, Bathurst, Maitland, and Moreton Bay, at which food and lodging were provided until offers of employment were made which the superintendents deemed fair. In the period 1832-50 89,251 migrants were introduced into New South Wales at public expense (including a few sent to Tasmania). During the same period 27,008 unassisted migrants arrived.

When gold was discovered in New South Wales in 1851 it was thought that migrants would flock thither, and the commissioners were asked to stop selected migration as soon as the funds in hand were absorbed. However, the Victorian fields attracted such large numbers from New South Wales that these instructions were countermanded, and the nomination system was further extended, as it was thought that family ties would keep nominees in the colony. To retain assisted migrants, an act of 1852 required that males and unmarried women should on arrival enter into an agreement to serve an employer for a term of two years at the current rate of wages, and to repay out of their wages the advance made towards their passage; repayments were to be made by the employers, who were allowed to deduct them from the migrants' wages. A migrant might at once repay the moneys due to the government, or might release himself at the end of a year's engagement by paying the second instalment. Altogether about 20,000 arrived in the colony under this new agreement, but many difficulties arose in connection with it, and towards the end of 1855 the clauses relating to indentures were repealed. The act of 1852 also provided for the private introduction of migrants under contract of service for five years; but very few were attracted, and it was decided to allow bounties on aliens introduced under two-year indentures. The German, Swiss, and Italian labourers who came out were generally considered more satisfactory than the British. During the period 1851-7, 56,530 persons were introduced into New South Wales at the expense of the land-fund.

Meanwhile the control of this fund had been transferred (by the constitution act of 1855) from the colonial office to the local legislature. No provision was made for allotting any part of it to immigration purposes, and thenceforth necessary funds had to be provided by parliamentary vote. Assisted immigration was unpopular among the employee class (see TRADE-UNIONISM), and it was proposed to substitute for it an offer of free land to migrants who paid their own passage. This suggestion originated with Dr. Lang, who had tried it in connection with his Moreton Bay parties; but it was not adopted, as the new land policy of 'free selection before survey' seemed likely to attract small farmers. In 1861, to further this result, Henry Parkes (q.v.) and W. B. Dalley (q.v.) were sent to Great Britain for a year to make known the advantages of New South Wales's new land act, but their mission was unsuccessful, partly because of the superior attractions of the Queensland scheme. After 1866 no further vote was made for immigration, and in December 1867 the nomination regulations were repealed. In 1869 there was some agitation for the renewal of assisted immigration, but a bill on the subject was withdrawn—largely owing to the attitude of Parkes, who opposed it on the ground that the colony had no agent in London to supervise selection.

In 1870 a select committee of the New South Wales legislative assembly recommended that an agent-general should be appointed with power to act as emigration agent; that greater facilities for settling on the land should be offered to migrants; and that the number selected from the three kingdoms should be proportionate to their population. As there was much unemployment in Sydney at the time, the revival of assisted immigration was bitterly opposed at public meetings and by deputations, and the bill was dropped. However, the emigration commissioners were authorized to send out domestics, and a few married persons accustomed to farm-work who were to look after the young women on the voyage. When Parkes became premier in 1872 he secured a vote of £50,000 to be expended during 1873 in assisting migrants selected by the recently appointed agent-general, Sir Charles Cowper. A denominational quota was determined by the number of persons professing each religion in the colony, and provision was made for limited immigration from Europe and the United States and for nomination by colonists. Only about 2000 persons were introduced during 1874-5, and in 1875 an unsuccessful attempt was made to take control out of the hands of politicians. In 1876 an act was passed validating contracts of service entered into by employers with foreigners, so long as the contracts were witnessed by authorized persons abroad and subsequently ratified in the colony. A few migrants were introduced at public expense during the next few years, but in March 1886 the nomination system was terminated (except as regarded settlers who wished to send for their families), and in October the agent-general was instructed to select no more. Early in the following year parliament decided to make no further provision for assisted migration beyond what was required to carry on existing contracts, under which migrants continued to arrive for a few years—but their total was only 1994. In 1873-93 New South Wales gained by assisted migration about 58,000 persons, and by unassisted about 231,000.

VICTORIA.—After separation from New South

Wales in 1850, Victoria took over the administrative machinery in Melbourne. Half the proceeds of the land-fund (after the deduction of certain expenses) were available for immigration, and arrangements were made with the commissioners to give assistance to farm-servants and shepherds, a limited number of artisans, and female domestics; provision was also made for assistance to migrants nominated by friends in the colony or by persons who had deposited money for the purchase of land; but nomination by land-buyers was discontinued in 1851, as it led to fraudulent practices. Many immigrants reached the colony without assistance, or with the help of charitable organizations. When gold was discovered in 1851 labourers everywhere left their jobs to try their luck on the fields, and a great scarcity of labour was felt in all industries; to meet this the regulations governing both selected and nominated immigration were relaxed for men bringing their families with them, as it was thought they would be less likely than single men to risk the hazards of the fields. During 1852 15,477 migrants were assisted to Victoria, as compared with 2551 the previous year. A committee appointed by the legislative council in 1853 reported that many of the newcomers were unsuited to colonial life, and recommended that assisted immigration should be confined to young single women, married mechanics, and married farm-labourers. Under these conditions the commissioners found it difficult to use the funds at their disposal without accepting large numbers of Irish applicants, who were objected to by an influential section of the community. The colonists also blamed the commissioners (quite unfairly) for the character of some migrants sent out by private institutions—not, however, by the Family Colonization Loan Society.

Meanwhile, as a result of the gold discoveries, a large number of persons had arrived without assistance, and in 1852-3 the government was obliged to make provision for housing them temporarily in Melbourne. Wooden buildings were hastily erected in which migrants were accommodated for ten days at a low charge, and the government subsidized private efforts to ameliorate the unusual conditions. During 1852 the colony's population increased from 97,000 to 168,000; the rush continued during 1853, but declined in 1854-5, by which time news of the disappointment that dogged the steps of so many prospectors was being circulated abroad.

When the first 'responsible' parliament met, considerable opposition to assisted immigration became evident, especially from members who relied on working-class votes. As parliament now controlled the funds, this opposition resulted in a vacillating policy. In 1860, when conditions had somewhat improved, regulations were made providing for the issue to colonial nominators of passage-warrants which could be used by male nominees on any available vessel; females must either form part of a family group, or travel in the ships of the land and emigration commissioners, who were still authorized to send out domestics. By the land act of 1862 one-fourth of the land-fund was set aside to assist migration from the three kingdoms in definite proportions; this remained in force until 1869. In 1863 an immigration act was passed which provided machinery for the use of the money thus allocated—by an agent-general in London, with four commissioners and a number of sub-agents; the act, however, was not enforced, and the land and emigration commissioners continued to act for the colony until 1869, though only a few thousands were sent out annually, owing to local opposition. A few specially skilled migrants were introduced from Europe. In 1869 the control of migration at the British end was taken over by the recently appointed agent-general, Sir George Verdon. The number of assisted migrants during the decade 1861-70 was 44,836, of whom 23,064 were Irish, 16,525 English, and 5247 Scotch; excluding these figures, the excess of arrivals over departures from 1 January 1865 to 31 March 1870 was only 7748. Some sections of the community desired the development of a more vigorous policy. There was sufficient support in 1870 to pass a vote of £65,600 for assisting selected and passage-warrant migrants, but in 1871 it was decided to terminate selection, and in 1872 the passage-warrant system was also brought to an end, except for some outstanding contracts which expired in 1873.

QUEENSLAND.—State-aided immigration has been an important factor in the development of Queensland. Reference has already been made to the advocacy by Dr. Lang of a land-grant to migrants who paid their own passage and would presumably be of a good middle-class type. When separation from New South Wales was effected, the system in operation in the mother-colony was at first continued, £5000 being voted in 1860 for the introduction of nominees and a few domestics, farm-labourers, etc., sent out by the land and emigration commissioners. But in the crown lands act of 1860 Lang's principle was adopted, provision being made for the issue of a land-order for £18 to any person coming from Europe at his own expense, or to any person who paid for the passage of a migrant; after two years' residence in the colony a second land-order for £12 could be claimed. Migrants claiming land-orders must come within the immigration regulations in force in the colony. On 9 October 1860 Henry Jordan was appointed emigration agent in England, to make known the advantages of the land-order system. He arranged for a direct shipping service to Queensland, carrying both paying passengers and persons whose passage-money was recouped by transferable land-orders issued in the colony. In January 1863 a supplementary scheme provided assisted passages for migrants willing to pay part of their passage-money without establishing a claim to a land-order. In 1861-3 about 17,000 persons reached Queensland under these schemes, the greater number being small capitalists with their families. Until 1863 most migrants came from England and Scotland, no agent having been appointed in Ireland; this occasioned discontent among the Irish, and a Queensland Immigration Society was formed (under the chairmanship of Bishop Quinn, q.v.) to extend the scheme to Ireland. The society was dissolved in the following year, and an agent appointed in Ireland. Arrangements were also made to secure about 2000 agriculturists from Germany, a considerable German population being already settled in Queensland. But the land-order system was abused; many migrants parted with their orders to land speculators, only to find themselves competing in the labour market on unsatisfactory terms. The government therefore decided to bring the land-order system gradually to an end, reverting to selective and nominated migration under the supervision of the land and emigration commissioners —who had continued to send out small groups of domestics. Jordan, faced with the destruction of

the system he had so elaborately built up, returned hurriedly to Queensland and induced the government to appoint a committee, which recommended the continuance of the land-order system with modifications. Each eligible applicant should receive a £30 land-order, but the deeds for the land should not be acquired until after two years' residence; the government should repurchase shippers' orders at a fixed price; migrants should be selected from the three kingdoms in proportion to their population, and not more than 1000 'statute' adults should be admitted annually from Germany. In 1864 the colony's first immigration act gave effect to these recommendations, and Jordan returned to England. Early in 1865 he was instructed to give free passages to nominees of Queensland railway contractors, selected through private agents; some of them were undesirable, and there were unpleasant incidents on their arrival. Moreover it was a time of financial distress in Queensland, and in September 1866 Jordan was instructed to terminate migration at public expense. The gross amount appropriated to the migration fund from 1 January 1860 to 31 December 1867 was nearly £580,000, of which £77,000 had been spent by the commissioners on the despatch of 8360 adults. During the same period 32,529 adults had been sent through the agency-general, and 5183 adults had arrived from Germany, making a total of 46,072 persons sent from Europe under some form of government supervision. The nominal value of land-orders issued was £660,072.

A select committee of the legislative assembly recommended in February 1868 a resumption of the land-order system with further modifications, but not until 1869 was an amending act passed; this provided for the issue of a non-transferable order for 40 acres of land to each full-paying passenger, subject to the homestead conditions of the land act of 1868. Provision was also made for assisting nominated and selected migrants, and for the grant of a number of free passages; but assistance granted by government had to be refunded within a stated time. When the repayments were made, the migrants became eligible for a 40-acre order on the same conditions as full-paying passengers. Employers were permitted to introduce migrants under a two years' agreement through government agents, if they guaranteed repayment in case of the migrant's default. At the end of two years the land-order would be issued to the man who made the refund. Employers were allowed to engage migrants at the depots on similar terms. Domestics, who were not required to repay their passage-money, had no claim to a grant. The quota system for migrants from the three kingdoms was to be continued, but the German quota was raised to 2000 per annum. It was estimated that the colony could absorb 6000 migrants per annum. An agent was sent to England and another to Germany, but the Prussian government refused to allow the indenturing of Germans. To many migrants the land-grants were valueless, as they lacked either the capital or the experience to cultivate land. Nor was it easy even for a migrant with experience and some means to find suitable and accessible land on which to settle. In 1872, therefore, orders were again made transferable, but the system had come into disfavour, and in 1875 the government decided to bring it to an end. In a parliamentary debate on the subject it was said that not more than two or three per cent of migrants entitled to land-orders had actually settled on the land; instead, they had by one means or another disposed of their orders to speculators and land-jobbers, at a discount in some cases of 75 per cent. Squatters found this an easy way to acquire, under the pre-emptive rights attached to their leases, the most valuable portions of their runs—the land-order system, it was said, turned the Darling Downs into a sheep-walk. But the amending act of 1875 was so clumsily drafted that another bill had to be introduced in 1882. Despite all these difficulties many assisted migrants arrived during the seventies—29,000 in 1870-6: in addition there was a continuous immigration from the other colonies, and the net gain to the population during the seven years was about 55,000. Assisted immigration was continued in 1877-8, restricted in 1879 owing to unsatisfactory economic conditions, and revived on a small scale in 1880, when there came into force an arrangement between the government and a shipping company for a regular service of steamers via Torres Straits to Brisbane.

By the act of 1882 the government was authorized to grant free and assisted passages, more assistance being given to nominees than to selected migrants; employers might also introduce migrants under contract through government agents on the same terms as nominees, and such contracts were validated in the colony by the act, as it was doubtful whether they could otherwise be enforced. No provision was made for repayment, but any person who came at public expense with the intention of leaving immediately might be fined £50 with or without imprisonment; leaving, or attempting to leave, within three months was made *prima facie* evidence of having arrived with intention to leave. In 1884 a land act set free for closer settlement large pastoral tenancies, but no special provision was made to attract small agricultural capitalists from Great Britain and Germany. In 1886 Griffith suggested that the land-order system might be satisfactorily worked if land-orders were used in payment of rent for crown land; a migrant taking up a selection of (say) 160 acres would pay his rent for five years with a £20 land-order and then under the land act get a free grant of it. This proposal was embodied in the crown lands act amendment act of 1886—Jordan being at the time minister for lands—and continued in force until repealed by the crown lands act of 1894. During the 1880s there had been a large influx of persons nominated by friends and, to a limited extent, by employers; free passages were no longer granted, and few availed themselves of the assistance offered to selected migrants. The immigration act of 1887 reduced the assistance given to nominees; this reduction did not apply to persons nominated by employers and coming under contracts of service, but there were few applicants of this kind. From 1892 to 1896 no assistance was given to migrants, except in respect of engagements already entered into; the practice was revived on a small scale from 1897 onwards, and at the time of federation a few domestics and agricultural labourers were being introduced.

SOUTH AUSTRALIA.—The land-fund of this settlement was originally intended for assisting the passage of migrants either selected by the South Australian commissioners or nominated by land-purchasers; migrants sent out at the expense of the land-fund were supported by the government until they found private employment. Gawler placed large numbers of them

on government works at reduced wages but in comparatively comfortable circumstances, so that many refused to face pioneering hardships—this situation helped to bring the colony into the difficulties from which Grey rescued it. Meanwhile the commissioners had in 1840 been absorbed into the newly-appointed board of land and emigration commissioners, who in 1841 suspended emigration to the colony. Under the land act of 1842 half the land-fund (minus certain expenses) was placed at the disposal of the commissioners for migration purposes, but it was not much used until 1845, when free passages were given to agricultural labourers, country mechanics, domestics, and a few miners. Philanthropic societies were also sending out migrants, partly at the expense of the colony, including children from the ragged schools, who were usually bound over by a local apprenticeship-board to responsible persons for three to five years. In 1845-51 21,770 migrants received government assistance; in addition, 34,659 (including 6700 Germans) came out at their own expense during the period 1844-51.

During the Victorian gold-rush of 1851-2 large numbers went thither, and it was obviously unwise to continue assisted immigration, except for nominees. Moreover the system of allowing land-purchasers to nominate persons for a free passage had been abused, and was shortly afterwards abolished. To keep the new settlers in the colony the commissioners bound them over to reside there for a definite period unless they repaid the money advanced; but it was found impracticable to enforce this agreement. However, successful diggers, returning with their gains, took up agricultural pursuits and created an increasing demand for labour, and more liberal assistance was given, but in 1855 the government found itself obliged to provide for about 1100 young women from Ireland and to open relief works for men. In 1857, after the grant of responsible government, the land-fund was merged in the general revenue; but, labour being again in demand, an immigration act of that year provided for the appointment of an agent in London to take the place of the commissioners. In January 1858 regulations under the act were issued, assistance being offered to both selected and nominated migrants (but not to Germans), who were required to stay two years in the colony. For migrants introduced at their expense settlers of a year's standing might receive a certificate with which land might be purchased. In 1860, owing to a depression in trade, assisted immigration was again suspended until the following year, when £25,000 was voted for it from the land-fund. In 1863 the 'Sutherland' act reserved one-third of the annual land-fund for immigration, which was thus freed from the vagaries of politics. Nevertheless, owing to an industrial depression in 1867 it was found impossible to utilize the funds thus made available; between 1 July 1863 and 30 September 1867 only £173,473 was expended out of an available £442,355. Between 1853 and 1866 46,942 'statute' adults came out at the public expense, of whom 27,445 were English, 14,134 Irish, and 5363 Scotch; the largest number in any one year was 10,584 in 1855.

In 1872 a new immigration act introduced a land-order system similar to that in operation in Queensland. Approved persons arriving at their own expense were to receive a land-order warrant for £20 per adult, which after two years' residence would be accepted by the government in payment for land. Introducers of approved migrants from Europe received a transferable order for £16 for each migrant who remained two years and (if a foreigner) became naturalized. Provision was also made for assisting nominees of residents who were natural-born or naturalized British subjects. The necessary funds were provided by annual votes. Lecturers were sent to Europe, but very few persons took advantage of the land-order system, and towards the end of 1876 it was decided to encourage nomination by allowing free passages to nominees. In 1873-6 12,175 assisted migrants of all classes were introduced. In 1877 it was decided to reduce assisted immigration to one ship-load monthly, and in 1886 the immigration regulations were suspended.

WESTERN AUSTRALIA.—Up to 1900 migration to Western Australia was spasmodic. Incomers up to the end of 1830 were entitled to a grant at the rate of 40 acres for every £3 of capital invested and 200 acres for the passage of each labourer paid by them; special terms were arranged with a few capitalists, notably with Thomas Peel and Colonel P. A. Lautour (see WESTERN AUSTRALIA). During 1831 this system was retained, but the size of the grants was reduced. When in that year land-sales were substituted for grants, such vast tracts of virgin country had been alienated that late-comers had difficulty in finding accessible land. Moreover, from the beginning there had been trouble between masters and their indentured servants, and the land-fund was too small to finance an assisted-immigration scheme. As a result the population, which numbered 1500 in 1832, had increased to only 4600 in 1849. An attempt had been made to check dispersion by a closer-settlement scheme at Australind (q.v.), and a few hundred migrants were introduced during 1841-3, but the settlement did not prosper. Early in 1850 a Colonization Assurance Company was formed in England to assist emigration to British colonies (see HUTT, JOHN) and about 100 migrants were sent to Western Australia. From 1850 to 1868 the colony received convicts under an agreement that as many free persons as convicts should be sent out; at first free settlers were sent at the rate of a few hundreds a year, but so difficult was it to obtain employment in competition with the ticket-of-leave men that the British authorities suspended free migration. In 1868 the legislative council of the colony was faced with the problem of labour-supply, and in 1872 residents were allowed to nominate friends or employees on depositing one-fourth the passage-money, the rest being found by the government. Efforts were also made to introduce settlers from the eastern colonies and from Europe, but without much success. In 1874 a select committee recommended that each 'statute' adult brought out at public expense should, after two years' residence, be entitled to select 50 acres of unimproved land, the fee-simple to be granted at the end of three years if certain specified improvements were made. This recommendation was accepted, and in August 1874 it was decided to devote £10,000 to immigration; E. H. Laurence, a resident magistrate of the colony, who was then in England, was instructed to make preliminary arrangements for the selection of applicants and for the despatch of nominees. When Laurence returned to the colony, this work was carried on by a 'colonial immigration committee,' consisting of a number of persons interested in the colony, but the result was not satisfactory. From 300 to 500 migrants

were sent out annually until 1878, when assistance was limited to a few nominees; in September 1879 it was unanimously agreed by the council that free land-grants should be discontinued. Meanwhile employers had turned to Asia for labour, especially for the development of the newly-opened Kimberley pastoral district.

In 1883 it was decided to appoint a board to administer a special fund of £20,000 for the introduction of 1000 migrants from Britain within the next two years, and the board was appointed on 6 November 1883. The crown agents in London were directed to supervise selected and nominated migrants; domestics and agricultural labourers were specially in demand, but the colony was also prepared to take lads from farm-schools as suggested by Laurence in 1874. Each applicant for assistance over 15 years of age was required to sign an undertaking to stay in the colony at least 12 months; any migrant leaving or attempting to leave within three months of arrival would be liable on conviction to a fine not exceeding £50 with or without imprisonment. Employers were permitted to use the crown agents or to select through private agencies. No provision was made for land-grants. Most of those sent out were nominees (a class specially approved of, as private interests tended to keep them in the colony), but a few were small capitalists. In November 1886 the immigration board, in view of an expected influx of migrants under the new railway schemes, decided to abolish free passages (except to a few domestics) but to continue the introduction of nominees at £6 each.

In 1884 a syndicate agreed to construct a line of railway from Albany to Beverley (243 miles), receiving in return a grant of 12,000 acres per mile constructed, the government retaining half the frontage to the line in blocks alternating with those chosen by the syndicate; an associated company, the Western Australian Land Company, would open up the land-grant, introducing 700 to 1000 settlers annually until the total reached 5000. A similar agreement for a line from York to Geraldton was made in 1886 with the Midland Railway Company of Western Australia. During 1886-7 the Western Australian Land Company introduced 1165 'statute' adults, but made no attempt to prepare the lands for settlement, and the colonization scheme was therefore a failure; in June 1887 it was arranged that only labourers required for the railway works should be introduced. The Midland Railway Company did not begin to open up its lands for settlement until 1900.

As the supply of labour was by 1888 in excess of the demand, the immigration board decided to reduce assistance still further. Owing to the gold discoveries of 1893 the colony between 1893 and 1900 gained from the eastern colonies (especially from Victoria and South Australia) about 108,000 persons. In those years assistance was given only to about 135 nominees yearly, most of whom were women. In September 1896 the legislative assembly resolved that farm and other labourers should be attracted to the colony, and that Dr. Barnardo should be invited to send out some of his boys; Forrest, then premier, promised to instruct the agent-general accordingly, but nothing came of it.

TASMANIA.—Under the assisted-migration policy of 1831 migrants were sent almost equally to Tasmania and to New South Wales, but in 1836 the island found it necessary to take fewer. In 1840, when assignment practically ceased, a large demand for labour was expected; bounty regulations like those adopted in New South Wales were put into operation in 1841, but were suspended in 1842. For the next few years the overplus of convict labour and the financial embarrassment of the government led to a loss of free population, and practically no free persons arrived until 1849—when, in accordance with the policy of Lord Grey, free settlers were sent out to offset the transportation of convicts. In 1852 a committee of the legislative council recommended that employers should be assisted to introduce indentured labourers; but the colonial land and emigration commissioners opposed the scheme, and it was limited to the appointment of an agent in Melbourne to select labourers from among disappointed gold-seekers on behalf of employers who contributed to their passage across the strait. Under this scheme about 1500 persons reached Tasmania in 1853-4, but were not very satisfactory, and in October 1854 the government withdrew its assistance. Meanwhile the council had been devising a bounty system which could be taken advantage of by employers or friends (bounty tickets in blank were also issued to overseas agents, charitable organizations, etc.), the migrants remaining in the colony for at least four years. In April 1854, in addition to the funds already at the disposal of the land and emigration commissioners, £50,000 was voted to carry out this scheme.

In 1856, assisted immigration having been temporarily suspended, a board of local immigration commissioners was appointed, and authorized to raise funds; the bounty system was resumed, though the issue of bounty tickets in blank was discontinued. But it proved difficult to retain migrants—indeed only in 1853, 1855, and 1857 did the number of arrivals materially exceed the number of departures. In 1864 a select committee suggested the issue of land-grants to full-paying migrants, and the immigration act of 1867 authorized the appointment of agents in Europe to grant land-order warrants; but in 1867-72 the land selected under this scheme totalled only about 1500 acres. Labourers were introduced in 1873 for the construction of the Hobart-Launceston railway, and with the development of tin- and gold-mining during the following decade conditions in the island improved. The immigration act of 1882 retained the land-order system and provided for assistance to other classes of migrants; an immigration board was set up, and given £10,000 per annum for three years to establish a satisfactory scheme; agents were sent to Europe, and about 2700 persons were introduced. In 1885, however, the board was dissolved and the migration policy practically abandoned, though assistance was given to a few nominees until 1891.

During the nineties none of the Australian colonies had any vigorous immigration policy, and in 1892, and again in 1898-1900 Australia lost population by departures in excess of arrivals; there was also during this period an intercolonial movement to Western Australia and Queensland. During the period 1861-1900 the net immigration (excess of arrivals over depar-

tures) into the Australian colonies was (including assisted and non-assisted migrants):—

Years.	N.S.W.	Vic.	Q.	S.A.	W.A.	Tas.	Total.
1861–65	11,562	5,656	52,855	16,263	4,165	–4,355	86,146
1866–70	33,309	30,218	15,041	965	1,699	–813	80,419
1871–75	29,741	–5,595	37,423	4,607	–98	–4,416	61,662
1876–80	73,459	–5,865	21,684	38,033	–49	2,880	130,142
1881–85	109,863	27,786	82,393	–2,082	3,658	2,422	224,040
1886–90	52,565	86,231	33,325	–24,205	8,179	2,606	158,701
1891–95	21,464	–46,848	4,666	471	47,201	–4,562	22,392
1896–1900	–997	–63,582	9,022	–15,866	68,996	4,914	2,487

(The minus sign indicates an excess of departures over arrivals.)

THE COMMONWEALTH.—Under the constitution the federal parliament was given power to legislate concerning migration, and in 1901 an act was passed embodying the 'White Australia' policy and specifying certain undesirable classes whose entry into Australia was prohibited (see IMMIGRATION RESTRICTION). But the restriction of undesirable immigrants is only one aspect of migration policy in a new country, remote from the original centres of its racial stock, where the development of natural resources waits on an increase of population. In 1904 Alfred Deakin (q.v.), then prime minister, declared it to be 'a matter of urgency to find some means of attracting the population needed to enable the Commonwealth to maintain her responsible position in these seas;' from that time onwards the problem of partially diverting to Australia the stream of settlers that flowed naturally from Europe to America was frequently before the Australian public. In 1905-6 suggestions were made that agricultural migrants might be obtained more easily from Europe than from Great Britain, and in 1905 Sir T. Coghlan, then agent-general for New South Wales, was instructed to make enquiries on the continent; he found, however, that most governments in northern Europe disliked losing their nationals by emigration. Meanwhile public opinion in Australia showed a bias against continental migrants; an Immigration League formed in New South Wales towards the end of 1905 was split on this issue, and a British Immigration League, the objects of which are indicated by its title, was organized. At the imperial conference of 1907 Deakin submitted a resolution 'that it is desirable to encourage British emigrants to proceed to British colonies rather than to foreign countries, and that the Imperial government be requested to co-operate with any colonies desiring immigrants in assisting suitable persons to emigrate;' but the British government was not prepared to subsidize emigration except by supporting the emigrants' information office which had been established in 1886 by the colonial office. Nor could the Commonwealth government enter on any active immigration campaign without the co-operation of the States, since the reception and distribution of migrants was a State and not a federal function. The Labour party opposed the assistance of any persons except settlers on the land —others might become competitors in the labour-market of the cities, which was frequently overstocked; and, since nearly all suitable land within reasonable distance of railways or other means of transport was in private hands, the provision of land for new settlers involved either the resumption of private estates or the development of railways and irrigation works. This could be done only by the States; the only Commonwealth instrument of closer settlement was a land-tax passed in 1910 by a labour government, for which see LAND LEGISLATION. Failing to secure general agreement among the States, the Commonwealth government refused to take control of the migration machinery in Great Britain, and limited its activities to a general advertising campaign which was begun in 1910; in the same year a 'Scottish Agricultural Commission' was invited to Australia to enquire into the prospects for British settlers, and its report, issued after a four months' tour (September 1910-January 1911), helped to stimulate British interest in the Commonwealth.

Meanwhile the States had taken independent action to encourage migrants for whom there was a special demand. Western Australia and Queensland had for a number of years been giving assistance intermittently and on a small scale; this they increased in 1906-7. Assisted immigration was re-introduced by New South Wales (1906), Victoria (1910), South Australia (1911), and Tasmania (1912). All States assisted nominees, but, as the majority of nominees were of the artisan class, it became necessary to recruit domestics and agriculturists. Occasionally specially skilled artisans were also introduced; Victoria under an agreement made between the government, the employers' federation, and the trades hall council brought in 1105 artisans and about 1000 factory girls in 1912. Special measures were taken to attract small capitalists with agricultural experience. For a time Queensland permitted agricultural settlers to select their holdings before leaving Great Britain (see BELL, SIR J. P.). In Victoria, New South Wales, and to a less degree South Australia, there was a demand for skilled irrigationists, and special facilities were given to experienced farmers from the western United States who wished to take up holdings (see IRRIGATION AND WATER CONSERVATION). In May 1910 the Victorian government sent Hugh McKenzie, minister for lands, and Elwood Mead, chairman of the State rivers and water-supply commission, to tour Europe and America in connection with its closer-settlement scheme; in July 1912 an officer was stationed in San Francisco to give information to applicants, and in the following year a lecturer was sent through America for the same purpose. Western Australia suffered in comparison with the eastern States because little was known in Great Britain of its agricultural possibilities, and in 1910 the premier, Sir Newton Moore, visited London to organize more effective propaganda. But experience proved that the adult migrant class in Great Britain was as a rule city-bred; moreover Australian farms rarely provide housing accommodation for a labourer's family, and this discouraged some who would otherwise have been prepared to go up-country.

In the circumstances zealous advocates of immigration (especially the British Immigration League) began to investigate the possibilities of juvenile migration. Before the war most of the States received a few boys for agricultural work, and either placed them with farmers or gave them a short preliminary training on government farms. In 1912 a first batch of boys was sent to New South Wales under the provisions of a private trust. A sum had been raised by public subscription for the

purchase of a battleship, but when the Commonwealth decided to build an Australian navy, half of the sum which had been collected was diverted to establish a 'Dreadnought' fund for the introduction of British boys between 14 and 18, and for their training on Scheyville farm at Pitt Town (near Windsor in New South Wales) in the elements of Australian agriculture. The 'Dreadnought' boys were of a better type than the average farm-labourer, and it was hoped that after a few years' experience they would take up land on their own account. The Western Australian government gave assistance to the Child Emigration Society of Oxford (founded by Kingsley Fairbridge), which sent out very young children and maintained them in a country establishment in Western Australia until they were old enough to go to work; and Henry Freeman took boys from the English ragged school union to a receiving-farm in Western Australia, from which they were drafted to private agricultural employment. In 1910 a special commissioner from the Barnardo homes investigated the possibility of placing children in Australia under the conditions that obtained in Canada; he reported that the children would not be properly cared for unless a large local staff of Barnardo inspectors was maintained—and the project was dropped for the time.

Speaking generally, the States recruited migrants through agents in the employ of shipping companies, who were paid a capitation fee for approved applicants; a few were also secured through philanthropic agencies. Assistance was given by direct contributions to the cost of passage, and by arrangements with shipping companies for reduced fares. There was marked competition between the States, and in 1912 at a premiers' conference it was decided to fix a minimum rate of passage-money and a maximum bonus for agents. In 1913 Victoria and New South Wales amalgamated their migration machinery in Great Britain. The majority of assisted migrants were British, though occasionally applicants from Europe were accepted —e.g. Western Australia found men from the north of Europe specially adapted for the heavy work of clearing land. Arrangements were made by the States for the reception of assisted migrants but were never very satisfactory except in Western Australia, where domestics were well cared for. The total number of assisted immigrants during the period 1911-14 was:—

Year	N.S.W.	Vic.	Q.	S.A.	W.A.	Tas.	Total.
1911	9,922	6,772	12,396	665	9,562	...	39,317
1912	14,956	15,112	6,462	3,212	6,970	(a)	46,712
1913	9,860	12,146	4,757	2,759	7,708	215	37,445
1914	6,655	7,496	4,096	644	1,729	185	20,805

(a) Not available.

The total number admitted was:—

1911	... 139,020	of whom	124,061	were British.
1912	... 163,990	,,	146,602	,,
1913	... 140,251	,,	122,443	,,
1914	... 110,701	,,	93,136	,,

The net immigration (excess of arrivals over departures) to the six States and two Territories of the Commonwealth was:—

Year	N.S.W.	Vic.	Q.	S.A.	W.A.	Tas.	N.T	F.C.T.	Total.
1911–14	88,514	52,027	29,335	3,935	23,219	-7,547	775	188	190,446

In 1915 immigration was practically suspended, and was not resumed until 1920. In that year the prime minister and the State premiers agreed that the Commonwealth should become responsible for the selection of migrants required by the States, and should supervise and assist their transport and the transport of approved nominees; the States undertook to receive and place them. Early in 1921 the Commonwealth took over all migration machinery in Great Britain, abolished the system of *per capita* payment to agents—which had been subject to abuse—and appointed a number of medical referees throughout Great Britain to examine applicants. It also subsidized the New Settlers' League, organized in 1921 to give assistance to migrants on arrival. A further extension of the system of assisted immigration was made possible in 1922 by the co-operation of the British government.

In 1917 a Dominions royal commission, appointed in 1912 by the British government to enquire into the best means of developing the natural resources of the Dominions and intra-Imperial trade, issued a final report in which it pointed out that the development of Imperial resources was hampered by the unsatisfactory distribution of man-power; the successful organization of migration, in its opinion, 'lies at the root of the problem of Empire development and largely upon it depends the progress of the immense territories of the Dominions and the increase of power of the Empire as a whole.' It suggested that openings should be found overseas for ex-service men and women, and that an increasing emigration of women and juveniles would be beneficial; it also advised the establishment of a special department to take over the supervision of emigration. Accordingly at the end of 1918 the emigrants' information office was superseded by a new body, later known as the oversea settlement committee. This committee was at first mainly occupied with administering the British ex-service passage scheme, under which 82,196 persons were placed in the Dominions between April 1919 and December 1922, 34,753 coming to Australia. In 1921 the British government called a conference on migration which recommended financial co-operation between the British and Dominion governments in a comprehensive policy of redistributing population, especially in connection with land-settlement schemes. To emphasize the unity of the Empire it was agreed that the terms 'oversea settlement' and 'oversea settlers' should be used in connection with intra-Imperial migration. These recommendations were accepted by an Imperial conference in the following June-August, and in 1922 the British government passed an Empire settlement act which empowered it to co-operate with any Dominion government in any scheme mutually agreed upon. The contribution of the British government, which was in no case to exceed half the expenses of any such arrangement, was limited to £1,500,000 for the first year, and £3,000,000 for each subsequent year, exclusive of any sums received as repayment of advances. As soon as the act was passed, negotiations were entered into between the Commonwealth and British governments which resulted in an agreement that one-third of the cost of passage of an approved settler should be contributed jointly by the two governments; advances covering the rest of the

passage-money might also be made under certain conditions. The assistance granted has since been increased, so that between 1 May 1925 and 30 April 1926 children under 12 years have been carried free, juveniles between 12 and 19 years have been required to pay a sum varying between £5 10s. and £11, and others £16 10s.—with special concessions for married couples. Advances to cover these sums may also be made by the two governments jointly. The passage-agreement applies both to nominees and to selected settlers. The results have not been so great as was expected. The Commonwealth is only authorized to select settlers in numbers and classes requisitioned by the various States. Domestics are always in demand; agricultural labourers can usually be absorbed, and artisans are occasionally sent for; there is a small but steady inflow of juveniles.

In 1922 the South Australian government passed an act which empowered them to apprentice British youths to farmers under official supervision, and this example was followed by Queensland and New South Wales, but the experiment has since been terminated in South Australia and New South Wales. Boys are still being assisted to New South Wales under the provisions of the Dreadnought trust, and receive a preliminary training on a government farm before being placed in private employment. Recently a 'Big Brother' movement has been organized in Australia on a small scale, each 'big brother' undertaking to keep in touch with a 'little brother' brought out from England; a first batch of 'little brothers' arrived towards the end of 1925. Since 1923 Barnardo children have been arriving in small batches, and children are still being sent to the Kingsley Fairbridge home in Western Australia.

The nominee is in a more fortunate position on arrival than the selected settler, since he has friends to assist him during the difficult period of adjustment. To extend the benefits of nomination to persons in England who have no personal friends in Australia, local organizations have been officially invited to associate themselves with organizations in Great Britain to effect 'group nominations;' the Australian organization arranges for the reception, placement, and after-care of a limited number of nominees whose names are filled in at the British end. A number of the Churches have responded to the invitation, and some 'group nominees' have already arrived under the assisted-passage agreement.

It has been estimated by the Commonwealth statistician that Australia's average annual capacity for absorbing immigrants has, over a long period of years, been 5½ per 1000. This ratio might be increased if sufficient capital for development schemes were provided and markets found. As has been stated above, the British government was empowered by the Empire settlement act to co-operate financially with the Australian governments in schemes for closer settlement. Negotiations were at once entered into by Western Australia, which resulted in an agreement between the government of that State, the Commonwealth, and Great Britain; Western Australia undertook to place 6000 settlers with their families on farms of their own at an estimated cost (excluding passages) of £6,000,000; the Commonwealth government was to raise the necessary loans, and the British government agreed to contribute a sum equivalent to one-third of the interest on the loans for a period of five years. The Western Australian government had in March 1921 given effect to its closer-settlement policy in the heavily-timbered south-western district; areas were developed on a group basis, the original groups being composed of persons with previous experience in Australia. Under the new agreement it was proposed to continue the experiment with British settlers, and 1352 were introduced. In 1924 the experiment was suspended, and a royal commission was appointed to enquire into conditions in the group-settlement area. In the majority report it was estimated that the farms which the State undertook to provide for £1000 were costing between £1400 and £1650, a sum considerably in excess of their market value; the British settlers were inexperienced, and no attempt was made to try them out at agricultural work before selecting them for the groups. In justice to them, however, the minority report pointed out that British settlers had not shown a greater tendency to leave their holdings than had the original Australian groups, the failures being British 31 per cent, Australian 41 per cent.

Agreements on similar lines were negotiated with the Commonwealth and the British government by Victoria and New South Wales, but were carried out on a much smaller scale than in Western Australia, and the migrants were not settled in groups. As a result of these experiments, and in view of the unsatisfied land-hunger of Australian citizens, a new agreement was made in April 1925 between the Commonwealth and British governments, whereby loan-money will be made available to the State governments at a low rate of interest to enable them to open up settlement areas and increase the carrying capacity of areas already settled; the maximum amount of loan-money provided for in the agreement is £34,000,000, to extend over a period of ten years; for every £75 made available to any State one British migrant is to be absorbed, not necessarily on the land. Western Australia (which is again taking families for closer settlement), Victoria, and South Australia have accepted these conditions; negotiations are still proceeding with the other States. The total number of assisted immigrants during the period 1921-5 was:—

Year	N.S.W.	Vic.	Q.	S.A.	W.A.	Tas.	Total.
1921	4,980	3,987	1,147	572	3,381	615	14,682
1922	7,087	9,145	1,711	1,531	4,373	411	24,258
1923	5,005	9,504	2,377	1,711	7,654	394	26,645
1924	6,211	8,721	1,788	1,375	6,715	226	25,036
1925	3,788	3,589	2,318	1,292	3,701	139	24,827

The total net immigration during the period was:—

Year	N.S.W.	Vic.	Q.	S.A.	W.A.	Tas.	N.T.	F.C.T.	Total.
1921	1,584	3,351	4,420	4,413	65	2,006	–254	69	15,654
1922	9,012	18,406	7,224	3,390	2,929	–3,212	–193	467	38,023
1923	3,492	16,497	10,789	4,823	5,283	–3,370	–30	56	37,540
1924	12,135	12,078	11,345	7,036	5,271	–4,495	29	350	43,749
1925	10,199	6,837	13,553	6,649	3,189	–4,029	56	903	37,357

The minus sign indicates an excess of departures over arrivals.)

Mikluho-Maklay, NIKOLAI NICOLAEVITCH (1846-1888), descendant of an old Cossack family, was born on his father's estate in the Ukraine in 1846 (some authorities say 1847). He commenced his studies at the university of St. Petersburg, but the rigours of the climate compelled him to leave Russia and work first at Heidelberg (where he studied law), then at Jena and Leipzig, where he studied various natural sciences, settling down in the end to comparative anatomy. In 1866 he joined Professor Ernst Haeckel in a visit to Madeira, the Canaries, and Morocco; in 1869 he travelled through the Red Sea, visited Asia Minor, and joined Dr. Dohrn at Messina in zoological researches which eventually led to the founding of a biological station at Naples. In 1871 he embarked in the Russian cruiser *Vitiaz* for a tour of the South American coasts and Pacific Ocean, was landed at Astrolabe Bay in New Guinea near Port Constantine—which he named after a Russian grand duke—and lived there among the native tribes for 15 months, establishing the most friendly relations with them. Rarely has a more daring adventure been undertaken in the cause of science. 'The happy effrontery of his unannounced visit' says Leonard Huxley, 'took their breath away. . . . He let them infer that he was invulnerable,' and showed no concern when spears were flung within six inches of his head or when a native offered to run him through. Believing that he had been killed, the Russian government towards the end of 1872 sent a warship to search for documents which he might have left behind, but it found him reluctant to leave. For reasons of health, however, he decided to return to civilization; but in December 1873 he started again for New Guinea, on this occasion settling for a few months at Koviai near Triton Bay and devoting great attention to the slave-trade that was going on in those regions—he made a report upon it to the Dutch government, and reforms were instituted. In November 1874 he began a year's sojourn in the Malay Peninsula; in January 1876 embarked in a trading schooner and visited Yap, the Pelews, and the Admiralty and other groups off the New Guinea coast; then revisited his friends on the mainland and was welcomed with great joy. This coast, from Astrolabe Bay eastwards, was already known as 'the Maclay Coast,' and Englishmen (e.g. Romilly) who landed there later found that a claim to be 'Maklay's brother' was a sure passport to safety and friendship. In November 1877 Maklay returned to Singapore, and in July 1878 visited Sydney as the guest of William Macleay (q.v.); on 26 August of that year he delivered an address before the local Linnean Society urging the establishment of a biological station on Port Jackson—a reminiscence of his work at Messina. But he could not settle down, and in March 1879 was off again on a tour of the Melanesian groups, interesting himself especially in the labour traffic between the islands and Fiji and Queensland. In April 1880 he was investigating the islands of Torres Straits; in May he went to Brisbane to collate and consider his results, and made an expedition to the Balonne River; at the end of the year he returned to Sydney, renewed his agitation for a biological station, procured a grant of land for it at Watson's Bay, and revisited New Guinea in H.M.S. *Wolverine*, to whose commander he made a report on the evils of the labour traffic. Then, taking advantage of the visit to Melbourne of a Russian squadron, he returned to Russia and was welcomed with honour, the Tsar undertaking the cost of publishing an account of his travels. In 1883 he paid another visit to Sydney and married a daughter of Sir John Robertson. About this time the question of annexing eastern New Guinea became urgent, and, when after much confusion and long delays the British government allowed Germany to take the northern coast down to 8° S. lat., Maklay grieved exceedingly over the loss of his friends, and besought both the British and the German governments for specially considerate treatment of tribes so much attached to him—who were, further, of a stock distinct from the mass of Papuans and more amenable to kindliness. He left Sydney finally in 1886, and died in 1888. The house erected for his biological station, which he for some time used as a residence and a storehouse for his valuable collections, was in the end taken over by the department of defence; the compensatory payment became the nucleus of a research fund now administered by the university.

His name, given correctly above, is often transformed to 'Nicholas de Miklouho Maclay,' which is the form used on the passport given him when he left Russia as a student, and which was consequently used by most European scientific bodies.

Military Defence. *Early Days.*—Until 1870 the defence of the Australian colonies by land was entrusted primarily to detachments of Imperial troops. Under Governor Phillip the settlement was policed by a detachment of marines, who in 1791-2 were replaced by a regiment, the New South Wales Corps (q.v.), specially raised for service in Australia. In 1800 Governor Hunter had reason to suspect that some Irish 'exiles' who had recently arrived were planning a revolt, and to strengthen the colony's armed forces he raised two bodies of 50 volunteers each at Sydney and Parramatta, styling them 'The Loyal and Associated Corps;' in July 1801, however, Governor King disbanded them because of a difficulty in finding officers. In 1803, on receipt of the news of a fresh outbreak of war between Britain and France, the volunteers were reinstated as 'Loyal Associations,' were armed, clothed, and victualled at the government's expense, and rendered good service in helping to put down the rising at Castle Hill in 1804. When Macquarie at the end of 1809 brought out his own regiment, the 73rd, the volunteers were again disbanded, the New South Wales Corps was sent back to England, and for the next 60 years the garrison was composed of British regiments, Sydney taking its place on the roster of garrison-stations of the Empire. The New South Wales Corps had been engaged mainly in police work, and this was for many years reckoned the chief, if not the only, duty of the British garrison. The list of regiments which so served in Australia, with the

dates of arrival of their first detachments and departure of their last, is given below.

During the wars with France (1793-1815) measures were occasionally taken to protect the settlement from attack, but these were only spasmodic efforts. The first fortification was started in July 1788 when Lieutenant William Dawes (q.v.) was ordered to construct a redoubt on the eastern side of the Cove. It was finished in November, a flagstaff was erected, and two pieces of ordnance were placed in position on New Year's Day of 1789. In 1791 fortifications were constructed by Dawes on the western side of the Cove, and a corporal's guard was mounted daily in a building which had been used by Dawes as an observatory; hence the point, though named by him Point Maskelyne, has become known as Dawes Point. Phillip in 1791 installed the Dawes Point battery; Hunter in 1798 installed that on Bennelong Point, and mounted a few guns on Garden Island; King, always expectant of French attacks, in 1801 placed a third battery on George's Head, and in 1804 began the construction of a 'citadel' on Windmill Hill (where the Sydney observatory now stands), from which both the seaward approaches to the Cove and the inland reaches of the Parramatta River could be commanded. This fort, which he named Fort Phillip, was a hexagon mounting four guns on each face. His enthusiasm lasted for two years, and then the building gangs were called away to other work. In 1807 Meehan's map shows the fort as 'irregularly begun, but now rebuilding,' but the last phrase was optimistic. Macquarie during his 11 years' rule strengthened the battery at Dawes Point, constructed a stone fort (afterwards known as Fort Macquarie) on Bennelong Point, and gave Fort Phillip a powder-magazine; his wish to build a bigger citadel at the fort-site, with the Dawes Point battery as an outwork, was thwarted by Bigge's desire to put a new gaol there. Bigge recommended the erection of a battery at South Head. The need, however, of retrenchment in expenditure and the widespread feeling that no nation would dare to attack a British settlement led to neglect of the forts, and in 1827 the colony's defences consisted only of the Dawes Point battery (then in bad repair) and Fort Macquarie. Darling protested in 1827 and again in 1828 that Sydney was 'totally destitute of every military defence,' and asked for an engineer officer to report on the situation, but he was repeatedly snubbed by the colonial office, and forbidden to begin any new work until it had been specifically approved by the British authorities. In 1833 Bourke asked the war office for an engineer officer, adding that the field-guns in store lacked both carriages to mount and men to work them, and the government in 1835 despatched George Barney (q.v.) to Sydney and another engineer officer to Hobart; the work was evidently expected to be light, for Bourke was ordered to use Barney as civil engineer also.

At Hobart Macquarie constructed a 9-gun battery, which he called Fort Mulgrave, on the southern point of Sullivan's Cove, and Arthur contemplated the construction of another on the northern point, where Sorell had reserved a site. But the authorities in London were more concerned about economy than about defences, and in 1827 Arthur had to report that out of £13,500 spent on defence in the previous ten years only £207 had been spent on Fort Mulgrave, and nothing at all on the proposed battery.

In spite of the governors' appeals little attention was paid by the British authorities to Australian defence until late in the forties; it was difficult to procure the necessary troops to garrison Western Australia, South Australia, Melville Island, and Port Essington; instructions from London bade them detach two companies here and another there until the garrison in New South Wales was almost depleted. In 1839 Barney recommended the construction of batteries on Bradley's Head and the little island known as 'Pinchgut' (q.v.), and asked for £5000 to spend on the defence of Sydney, Newcastle, Wollongong, Port Macquarie, and Port Phillip; but even this modest request was refused. In 1840, however, he levelled the sites for the two Sydney batteries, Gipps having become so desperate that he ordered him to begin work, with the full knowledge that both of them were committing a grave breach of discipline. As the work was done by convicts and so cost only £300, the expenditure was sanctioned, but Gipps was forbidden to go on.

In November 1846 Earl Grey peremptorily ordered FitzRoy to send at least 900 men to New Zealand, where order was being slowly restored among the Maori tribes; the gap in New South Wales, wrote Grey, could easily be filled by the enlistment of local police or militia. In October 1847 he warned FitzRoy that, as the convict establishment in New South Wales was to be broken up, the British garrison would soon be greatly reduced. FitzRoy had already (in August 1847) forwarded to the colonial office an appeal from the New South Wales legislature for aid in strengthening the defences of Sydney, which were hopelessly inadequate and out of repair—in 1839 two United States cruisers under Commander Wilkes had entered Port Jackson and anchored off Circular Quay at night-time, their arrival remaining unknown till daylight. But Grey was obdurate. Sydney must take care of itself, he wrote; if forts were needed, the colony must pay for them, though Britain would willingly lend engineers to design them; if an artillery force was desired, Sydney and Melbourne could easily create one, 'composed of the labouring population of these towns, and officered by the inhabitants of higher station.' In November 1849 Grey announced that all barracks and military buildings would be handed over to the colonial authorities, that all military expenses other than the pay of the troops must be borne by the colonies, and that the garrison would be reduced to a guard in Sydney and another in Melbourne. If the colonies wanted more troops, they could pay for them; if the barracks, etc., were not properly kept up, all troops would be withdrawn. In June 1850 he offered an additional regiment and a detachment of sappers and miners, provided that the colony paid all expenses save transport.

In November 1851 the legislative council refused to contribute towards defence (even towards that of Port Jackson) until it was given control of the colony's revenues. The gold-rush of 1851 and a change of ministry in Britain postponed the bickering until October 1853, when the legislative council—having been assured that it would shortly acquire full control of all revenues—sanctioned the erection of forts on South and Middle heads. This activity was greatly stimulated by the outbreak of the Crimean war, and a volunteer force (to be described later) was authorized in August 1854. The situation arising out of this war led to a reorganization

of the imperial forces in Australia, the headquarters being moved from Sydney to Melbourne —which from the British point of view was the most central point and had the advantage of receiving its mails more quickly from London. Until 1854 no serious attempt was made to put Melbourne in a state of defence despite its rapidly increasing importance; but early in that year the Victorian government agreed to meet practically all expenses of the imperial forces (about 700 troops of all arms). About the same time a report was received from Captain Ross, R.E. (who had been ordered to draw up plans for harbour defences), recommending that two steam guardships should be stationed in the port, and 2000 troops of the line, with a company of engineers and another of artillery, in the colony; he was opposed to fortifying the Port Phillip heads. In August 1854 Sir R. Nickle (q.v.) with the headquarters staff reached Melbourne, and there followed a short period of active preparation for defence. Work was begun on extensive military barracks in the St. Kilda-road, and on the Williamstown and Sandridge batteries, but enthusiasm soon waned. In 1858 a new agreement came into force, whereby the colony provided barrack accommodation and colonial pay and allowances for imperial troops, imperial pay and allowances being paid by the British government; a similar agreement was made by the other Australian colonies, and there was no further change in the conditions until 1863. For some time departmental and parliamentary committees in London had been protesting against the maintenance of colonial garrisons which cost the mother-country nearly four millions per annum, whereas the colonies paid only £380,000 (these figures refer to all British colonies, not to Australia alone). Nothing, however, was done until in March 1862 the house of commons resolved that colonies under responsible government ought to bear the whole expense of their internal defence, and to assist in their external defence as well. Acting on this resolution, the British government in 1863 notified the governments of the Australian colonies that for the future naval protection must be considered to exhaust British responsibility. For land defence Britain was willing to lend Australia 15 companies of infantry (see the following table), to be paid for at the rate of £40 per man per year; if more were wanted, or if artillery were preferred, the rate for the extras would be £70. Further, no guarantee could be given that the troops would not be withdrawn in an emergency.

Colony.	Number of companies.	Number of officers.	Number of men.	Officers and men.	Annual payment by colony.
					£
New South Wales.	4	19	340	359	14,360
Queensland	1	3	88	91	3,640
Victoria ...	5	22	423	445	17,800

South Australia.	2	6	166	172	6,880
	15	61	1,266	1,327	53,080

In 1866 Victoria asked for artillery instead of infantry, but the request was refused. In 1869 the Victorian premier, James McCulloch, notified the colonial office, through the governor, that Victoria would vote no more subsidies for British garrisons, unless (*a*) artillery were substituted for infantry, and (*b*) a guarantee were given that the artillery contingent would remain in war-time. The colonial office replied that in all probability all troops would be withdrawn from Australia in the near future, but no definite decision would be made until the views of other colonial premiers had been ascertained. At the intercolonial conference of 1870 it was agreed that the conditions laid down for the maintenance of British troops in Australia were not acceptable, and that the colonies would have to rely on their own resources for military protection; on the other hand, the naval defence of the Australian coast-line and of the commerce in its ports was a matter primarily for the Imperial government. The British troops were thereupon withdrawn. The following table exhibits a list of the various regiments which have served in Australia:—

Regiment.	Year of arrival.	Year of departure.
73rd (Highlanders)	1810	1814
46th (South Devon)	1814	1818
48th (Northamptonshire)	1817	1824
3rd (Buffs)	1823	1827
40th (2nd Somersetshire)	1824	1829
57th (West Middlesex)	1825	1832
39th (Dorsetshire)	1827	1832
63rd (West Suffolk)	1829	1833
17th (Leicestershire)	1830	1836
4th (The King's Own)	1832	1837
50th (West Kent)	1833	1841
21st (Royal North British Fusiliers)	1833	1839
28th (North Gloucestershire)	1835	1842
80th (Staffordshire Volunteers)	1837	1844
51st (2nd Yorkshire West Riding Light Infantry).	1838	1846
96th	1841	1848
99th (Lanarkshire)	1842	1856
58th (Rutlandshire)	1844	1847
11th (North Devonshire)	1845	1857
65th (2nd Yorkshire North Riding)	1846	1849
40th (2nd Somersetshire)	1852	1860
12th (East Suffolk)	1854	1861
77th (East Middlesex)	1857	1858
50th (West Kent)	1866	1869
14th (Buckinghamshire)	1867	1870
18th (Royal Irish)	1870	1870

Some of the regiments in this table were represented by detachments only. The 28th was due to leave New South Wales in 1843, but Gipps, having received in May 1842 the news of the disasters in Afghanistan, despatched the regiment to India during June, and was thanked by the British government for so doing.

Locally Raised Forces.—With the inception of locally raised forces begins the history of six separate movements which were not co-ordinated until the Commonwealth came into being.

After the disbandment of the Loyal Associations in 1810 no further effort to raise defence forces locally was made until 1854, when the Crimean war stimulated *New South Wales* into raising a rifle regiment, a troop of yeomanry, and a battery of artillery. The regiment —about 330 men in six companies, known as the 1st Sydney battalion of rifle volunteers— is considered to be the infant form of what is now the 1st battalion, Commonwealth military forces; the yeomanry mustered only 28 troopers in 1855, and in 1856 had disappeared. In 1859 rumours of war in New Zealand and of French designs against England revived volunteering, and in 1860 a much larger force—14 companies of rifles in Sydney, six in the country districts, one troop of mounted rifles, two batteries of artillery in Sydney and one at Newcastle—was raised and equipped; by January 1861 nearly

1700 men had been enrolled. The mounted troops were disbanded in 1862, and the rest of the force steadily dwindled until October 1867, when interest was revived by the passing of an act granting 50 acres of land to every volunteer who should complete five years' continuous and efficient service. In 1868 a Scottish regiment —the Duke of Edinburgh's Highlanders—was raised, and in 1869 a corps of engineers; in 1870, when the British garrison was withdrawn, a paid force was raised—a battery of artillery and two companies of infantry—but the infantry was disbanded in 1872. For some years the battery was the only regular force New South Wales possessed, and in 1876-7 additional batteries were raised. Meanwhile the land-grant system had proved unsatisfactory, as the grantees in many cases sold their orders to the highest bidder; in 1874 the system was abolished, and recruiting markedly declined. The Scottish regiment disappeared in 1878.

It is convenient to insert here a further instalment of the story of New South Wales fortifications. In 1854 Port Jackson was being gradually protected by a scheme involving batteries on Dawes Point, Pinchgut, Bradley's Head, George's Head, Middle Head, and South Head, George's Head being the principal fort. But in 1855 the new governor—Sir William Denison, a captain of engineers who had learned his engineering 30 years before—persuaded the legislative council to dismantle all the outside forts and revive the long-since discarded scheme of defending the inner port alone. Pinchgut—henceforth to be called Fort Denison—was the central point of his scheme, supported by batteries at Dawes and Kirribilli points and Mrs. Macquarie's Chair, and by a renovated Fort Macquarie. Over £60,000 was spent on this absurd scheme, which was abandoned during the sixties, when the scheme of 1854 was readopted. By 1872 the forts at Bradley's, George's, Middle, and South heads had been constructed and armed with guns ranging from 68-pounders to 18-ton muzzle-loading rifled cannon.

In *Victoria* the alarm caused by the Crimean war produced in 1854 the Melbourne volunteer rifle regiment, with an establishment of 2000 men, the Victorian volunteer yeomanry corps, and the Geelong volunteer rifle corps. But, as in New South Wales, the excitement waned, and by 1858 the total strength had dwindled to about 800 men. In July 1859 rumours of a probable European war reached Melbourne, and volunteering was revived; but not till 1860, when the British garrison was withdrawn for service in New Zealand, was there any enthusiasm. Ten companies of rifles were formed of volunteers drawn from Melbourne (proper), North Melbourne, Collingwood, Richmond, Prahran and South Yarra, St. Kilda, Emerald Hill, Hawthorn and Kew, Pentridge, Williamstown. A company of artillery was also raised from the seaport towns of Portland, Belfast, and Warrnambool. The Richmond company evolved into the Yarra Borderers (now the 22nd battalion, Commonwealth military forces), and two others—North Melbourne and Melbourne—were the nucleus of the 51st regiment, Commonwealth military forces. In 1863 the volunteer force was reorganized under a scheme providing for 13 rifle companies, seven artillery companies, an engineer corps, and a 2-companied naval brigade; by the end of the year over 3600 men were enlisted in these companies. In 1865 the laws relating to volunteering were consolidated, a land-grant scheme like that of New South Wales being adopted. In 1870, when the last British troops left Victoria, a permanent paid artillery corps (later the Victorian permanent artillery) of about 120 men was raised, and by 1872 the Victorian defence forces totalled nearly 4000.

Meanwhile the authorities responsible for Victorian defence had decided that the only form of attack likely to be made on the colony must be a raid on Melbourne, which could be best guarded against by blocking the passage through the heads of Port Phillip. More and more stress was laid on artillery, and in 1875 it was decided that 2000 out of 3400 men should be artillerymen. Forts commanding the heads were constructed near Queenscliff.

In *South Australia* also an impulse towards volunteering was given by the Crimean war, and steps were taken to raise 2000 men; on 24 May 1855 a troop of mounted rifles, two battalions of infantry, and two companies of artillery were reviewed. As in the other colonies, enthusiasm languished when the war was over, but revived in 1860, when about 600 men rejoined the ranks. The 1st Adelaide rifles, then constituted, have become the 10th battalion, C.M.F. In November 1862 the South Australian defence forces numbered 2008 of all ranks. The force of 1854-5 had been partly paid, but that of 1860-6 was on a volunteer basis: in 1866 it was disbanded, and a partly paid force of about 800 men was substituted, the pay being 5s. per day of actual service. In 1867 the rate of pay for the artillery was increased, and authority was given to raise mounted troops. At this date the volunteer troops in South Australia consisted of one battery of field artillery at Adelaide and one cavalry squadron of four troops, which were designated No. 1, Mylong troop; No. 2, Strathalbyn troop; No. 3, Adelaide troop; No. 4, Reedbeds troop. The infantry consisted of the South Australian (Prince Alfred's Own) volunteers. No. 1, No. 2, and No. 4 companies were raised in Adelaide, No. 3 in Kapunda, No. 5 at Gawler, and No. 6 at North Adelaide.

In the other Australian colonies the raising of local forces proceeded on similar lines, but on a smaller scale. *Queensland* in 1860 formed a troop of mounted rifles, and within a few years added infantry and artillery. In 1862 the strength of the troops amounted to:—

Brisbane light horse	10
Ipswich light horse	15
No. 1 battery artillery, Brisbane ..	34
Maryborough rifles	3
No. 1 company, Brisbane rifles ..	43
No. 2 company, Ipswich rifles	49
Rockhampton rifles	94
	248

The Brisbane light horse and the Maryborough rifles ceased to exist in 1863. In 1876 the total strength was only 415.

In *Tasmania* the first local force was raised in the year 1859 and consisted of Hobart Town artillery, Launceston artillery, 1st rifles (Hobart), 2nd rifles (Hobart), 3rd rifles (Hobart), Buckingham rifles (Newtown), City guards (Hobart), Kingsborough rifles (Kingston), Derwent rifles (New Norfolk), Launceston rifles, Longford rifles, Huon rifles (Franklin), Westbury rifles, and Deloraine rifles. A mounted corps was raised in Launceston in 1860; it consisted of about 43 of all ranks under the command of Cornet Barnes. On 1 October 1861

the total strength of the troops in Tasmania was 72 officers and 1120 other ranks. In 1867 the Victorian example led to the creation of a third battery, the infantry being disbanded. In 1870 the vote was dropped from the budget, and the colony remained without a defence force until 1878.

In *Western Australia* the volunteer forces were organized by the officers of the 12th regiment of foot (which was stationed in the colony in 1858) and consisted of Perth horse artillery, Pinjarrah mounted rifles, Wellington mounted rifles, Perth metropolitan volunteers, Fremantle rifle volunteers, and Geraldton rifle volunteers. This force consisted of about 700; each volunteer enrolled was entitled to a grant of 50 acres after five years service. Little interest was taken in the movement, and a 'Pensioner Force' was formed from a number of pensioners who were afterwards employed on various military duties; but the colony did not obtain responsible government until 1890, and was therefore not considered responsible for its own defence.

The Jervois-Scratchley Reports.—In 1876 the colonial governments began to take stock of their defences, and were much dissatisfied. They asked the British government for advice, and early in 1877 Sir William Jervois (q.v.), then governor of the Straits Settlements, and Major Peter Scratchley (q.v.), who had in 1860-3 designed the first defences of Hobson's Bay, were commissioned to advise on a correlated scheme of seaport defence. In 1878 Jervois was appointed governor of South Australia—a comparatively leisured post—in order to give him freedom for travel, and Scratchley was made commissioner of defences for all the colonies except Western Australia. From 1877 to 1883 the two advisers worked at their reports, basing particular recommendations on the general principle that attack should be met (*a*) by armed vessels operating in the open sea, (*b*) by battery and torpedo defences, worked from powerful armoured forts with the heaviest guns available, (*c*) by a well-trained field force, consisting largely of volunteers but with a nucleus of permanent paid men. The volunteers, too, ought to be partly paid, since their training in camp and otherwise would thus be ensured.

The general result of this investigation was the gradual reorganization of all the colonial forces on a single plan, with variations depending on the population and revenues of the various colonies. A small force of 'permanent' soldiers was allotted to man the fortifications and carry on staff work. The bulk of the troops was organized as 'partially paid' militia; the report recommended that:—

> The officer commanding the force may order such parades as he may consider necessary, provided that no part of the cavalry or infantry shall be called out for more than thirty-six whole or seventy-two half-days in one year, nor the artillery more than forty-eight whole or ninety-six half-days in a year, and the reserve not more than twelve times in one year.

Among them would be bodies of field artillery, engineers, and torpedo experts, the latter all engineers or skilled electricians in private life. Unpaid volunteers Scratchley considered unsatisfactory because effective training could not be enforced on them; he strongly recommended the formation of reserves, to consist of men who had served for three years in the militia and were willing to undergo a certain amount of training for another five years. In 1884, at the beginning of this development, the colonial troops were classified as follows:—

Colony.	Infantry.	Artillery.	Engineers.	Torpedo force.	Mounted force.	Total.
New South Wales—						
Permanent ...	...	319	...	...	...	319
Militia	1,340	300	60	100	...	1,800
Victoria—						
Permanent ...	...	125	...	...	...	125
Volunteer.....	2,191	1,016	250	18	125	3,600
South Australia—						
Permanent ...	...	50	...	...	...	50
Militia	780	150	...	...	...	930
Volunteer.....	900	...	...	...	...	900
Queensland—						
Volunteer.....	755	250	60 (including torpedo force.)			1,065
Tasmania—						
Volunteer.....	414	200	...	...	20	634
Total	6,380	2,410	370	118	145	9,423

In March 1901, when the forces of the six colonies were consolidated under the Commonwealth, their strength was as follows:—

State.	Permanent.	Militia.	Volunteer	Total.
New South Wales	669	5,549	3,493	9,711
Victoria	443	3,554	2,602	6,599
Queensland	301	4,053	654	5,008
South Australia	51	2,949	.....	3,000
Western Australia.	50	.....	2,235	2,285
Tasmania	30	.....	2,377	2,407
Total ...	1,544	16,105	11,361	29,010

The permanent forces included chiefly the administrative staff and garrison artillery; in the larger States the volunteers were almost entirely infantry, engineers and field-artillery being supplied by the militia, which also accounted for a large part of the infantry and most of the mounted forces.

This improvement both in organization and in numbers (from 9423 in 1884 to 29,010 in 1901) was mainly due to the Jervois-Scratchley reports, but in the interval two other influences had been at work. In 1885 expectations of war with Russia—the same which put a hasty end to the Sudan campaign (q.v.) of that year—gave a fresh impetus to volunteering. In *New South Wales* a light horse regiment (afterwards known as the New South Wales lancers) and the Scottish rifles were the firstfruits of this enthusiasm; by 1893 the lancers and several smaller volunteer bodies had been absorbed into the militia, but the Scottish regiment persisted, and in 1895—thanks to the support of General Hutton (q.v.)—was joined by Irish rifles and St. George's rifles. In 1897, under General G. A. French (q.v.), the volunteer strength nearly quadrupled, the Australian horse, Australian rifles, Railways corps, and National guard were formed, and the existing regiments greatly increased their strength. In 1898-9 the Scottish rifles established companies in Newcastle, Maclean, and Lismore on the north coast; and by the end of 1900, when the stimulus of the South African war (q.v.) had had time to act, the four rifle regiments averaged over 660 men each and smaller bodies were in process of formation. In *Victoria* the course of events contrasted curiously with that just narrated.

During 1884 the volunteer forces were entirely replaced by militia, rifle clubs being established to absorb such volunteer enthusiasm as could not find time for regular training. In 1885 the country districts formed a regiment of mounted rifles, to whom small payments were made, and in 1888 an infantry regiment, the Victorian rangers, was raised under similar conditions in the same areas. In 1897 a Scottish regiment, purely volunteer, made its appearance. *Queensland* in 1885 followed the example of New South Wales and raised a Scottish volunteer regiment (which disbanded in a few years); otherwise the development of the Queensland forces proceeded along the Jervois-Scratchley lines, as did that of *South Australia*, though there volunteering was still encouraged. *Tasmania* remained dependent on its volunteers, who in 1898 were organized in a single 3-battalioned infantry regiment.

Under the federal constitution a Commonwealth ministry of defence in 1901 took control of all the State forces. The task of welding them into a homogeneous army was entrusted to Sir Edward Hutton, who in 1901-4 laid the foundations on which all subsequent organization was based. The defence acts of 1903-4—which, with the regulations made under them, still constitute the legislative basis of the Australian military system—empowered the governor-general to arrange for the defence of the Commonwealth, to appoint and promote officers, and to determine military districts and sub-districts. In time of peace enlistment was voluntary, but in time of war the governor-general might call out all males between the ages of 18 and 60 for service within the Commonwealth. The Imperial army act was declared to apply to Commonwealth forces on active service, except in so far as its provisions were inconsistent with the defence acts. The military system included permanent troops and citizen forces (militia and volunteers), with a reserve consisting of officers who had retired from active service and members of rifle clubs duly enrolled. A 'Royal Australian Garrison Artillery Regiment' provided garrisons for the principal forts, with a militia garrison artillery as relief for certain strategic positions and defended ports. Arrangements were made for the maintenance of cadet corps. The militia was given a standard of efficiency, inefficients being discharged. The Commonwealth was divided into military districts roughly corresponding to the six States; and provision was made for the building and equipment of forts, the institution of arms and ammunition factories, and the control of railways and tramways when needed for the transport of troops on active service. In 1905 a council of defence to determine questions of policy, and a military board to supervise administration, were duly constituted.

Though federation had distinctly improved the military defence of Australia, the voluntary system which obtained in peace-time seemed to many public men inadequate for defence in an emergency. In September 1905, therefore, an Australian National Defence League was formed, with the object of securing universal compulsory training (military or naval), on Swiss lines, of the boyhood and manhood of Australia. During the defence debates of 1902 William Morris Hughes had tabled a motion in favour of compulsory military training for adults, but it had been rejected; thereafter the matter was frequently discussed in parliament; but no definite action was taken until in December 1907 Alfred Deakin (then prime minister) on his return from an Imperial conference made his policy speech on defence. He accepted the principle of compulsory training, limiting it for the time being to males in their 19th, 20th, and 21st years; later, he proposed to extend it in some form to lads of from 12 to 18 and to adults between 21 and 26. The training immediately proposed was a continuous training of 18 days in the first year, 18 in the second, and 12 in the third, trainees with satisfactory cadet experience being allowed shorter terms. As a rule no payment was to be made. A military college was to be opened for the training of officers and a cordite factory established. In September 1908 a defence bill embodying the general substance of this policy was introduced; before it became law, however, the Labour party was in power—and the Labour policy, as explained by the prime minister in March 1909, was more strenuous. It included compulsory training for lads between 12 and 18—day or half-day drills, or school instruction; compulsory training for adults of 18-20 years, in the form of a continuous camp for two or three weeks each year; and a voluntary annual camp for adults of 21-30. Time spent in camp was to be paid for. But the Fisher ministry was out of office before the bill had been prepared, and Deakin on his return to power re-introduced the defence bill of 1908 in a modified form. Compulsory training was to be effected by division into junior (12-14) and senior (14-18) cadets, and citizen forces (18-20). The volunteer system was to be terminated, but the militia maintained and recruited up to war-strength from the trainees on the completion of their service. Trainees who did not join the militia would pass into the reserves until their 26th year, and would be obliged to register in their residential districts annually. Days spent in camp were to be paid for. Provision was made for a military college and a school of musketry. This bill was passed, but before it came into operation Lord Kitchener, at the invitation of the Commonwealth government, visited Australia to report on the military forces, forts, and other defence works. His report, issued early in 1910, estimated the strength of the land forces necessary for Australia's safety at 80,000, one half to secure the larger cities and defended forts from attack and the other to operate as a mobile striking force. To raise this force within a reasonable time he advised the extension of compulsory training to the 25th year, the reserve to consist of trainees in their 26th year. In addition to continuous training in camp, instruction should be given at drills. The only way, said Kitchener, of organizing a satisfactory citizen force was to divide the Commonwealth into areas from which the military units would be drawn. Each area should provide a definite proportion of a fighting unit, and should be in charge of a thoroughly trained permanent instructional officer, assisted by one or two non-commissioned officers. Ten areas should form one group under the supervision of a superior instructional officer, who would become brigade-major in time of war. The extent of the 'area' must depend on the density of population. In the cities two, and in the country three, areas should be allowed per battalion of infantry. The area officer's duties would include the inspection of junior cadets, the organization and training of senior cadets, and all matters relating to the enrolment, equipment, organization, and training of the adult soldier. Kitchener

further recommended the formation of a staff corps drawn from the proposed military college.

An amending act was passed in 1910 which embodied Kitchener's recommendations. It defined the classes exempt from service—persons with religious objections, school-teachers qualified as naval or military instructors, members of parliament, magistrates, constables, hospital doctors, etc., all coming under the listed exemptions. The act was proclaimed on 1 January 1911, arrangements were at once made for the training of 200 non-commissioned officers for the instruction of the new army, and compulsory training commenced on 1 July. The training of junior cadets began on the first day of July in the year in which the person liable reached the age of 12 years and continued for two years, the annual training being 90 hours' drill; that of senior cadets began on the first day of July in the year in which the cadet reached the age of 14 years and continued for four years, the annual training being 4 whole-day drills (of 6 hours), 12 half-day drills (of 3 hours), and 24 night drills (of 1½ hours) or their equivalent. For the citizen forces the training was for seven years, comprising annually 16 whole-day drills, of which not less than 8 must be passed in a continuous camp. The Commonwealth was divided into 224 training areas, which constituted 92 battalion areas, 4 battalion areas being grouped into a brigade area. The members of the old militia army were permitted to complete the three years for which they had enlisted, and the militia system was then abandoned, only the officers and non-commissioned officers being allowed to re-engage in the citizen forces.

The Royal Military College at Duntroon, Federal Territory, was opened in June 1911. Admission to the college is by open competitive examination, a definite number of vacancies being allotted to each State on a population basis; the age for admission is between 16 and 19 years. The normal course lasts for four years and is followed by a turn of duty in England, India, Hong Kong, or Singapore, after which graduates are appointed to the permanent staff. No fees are charged for maintenance and instruction, and each staff-cadet receives an allowance for incidental expenses.

As recommended by Kitchener, a war railway council consisting of military and railway officers was instituted in 1911. Its chief duties are to furnish advice and information on railway transport for military purposes and to secure co-operation between the Commonwealth defence department and the States' railway departments in regard to the concentration and mobilization of troops.

Slight modifications in the defence acts were made during 1911 and 1912. On the outbreak of the European war in 1914, the Australian forces, though already showing much improvement in training and numbers, consisted chiefly of young men from 19 to 21, who were hardly suited to form the nucleus of an oversea contingent. Consequently the Australian Imperial Force (q.v.) was organized and maintained as an entity distinct from the citizen forces, whose liability was limited to home service. But when the war was over, it was decided to change the numbers of units and formations of the citizen forces to correspond with those of the A.I.F., in order to maintain traditions established at the front. The divisional organization which had evolved in the A.I.F. was, therefore, on 1 April 1921 applied to peace conditions with a minimum of permanent staff. In October 1916 a referendum was held on the proposal to empower the government to conscript citizens for military service outside the Commonwealth during the war, and was rejected. A second and greatly modified proposal was submitted in December of the following year but this also was rejected—indeed, by a much larger majority (see REFERENDA).

Following on the international conference held at Washington in 1921, the Australian government decided to restrict the operation of the compulsory training provisions of the defence acts to the more populous centres and to certain quotas, training being confined to cadets from 16-17 years of age and to citizen soldiers from 18-19 years. Junior cadet training ceased as an activity of the defence department on 30 June 1922. The existing divisional organization of the field force is being retained in skeleton form, the units being much below their war-strength. At the same time a number of the military and civil personnel of the department were retired. Meanwhile on 3 August 1921 the administration of the rifle clubs had been transferred from military to civil control.

The allotment of units to areas of the Commonwealth citizen forces at 1 February 1924 is shown in the following table:—

State.	Brigade Areas.	Battalion Areas.													Training Areas.
		Number of Areas.	Providing the undermentioned Units.												
			Infantry Battalions.	Light Horse Regiments.	Field Artillery Batteries.	Engineers.		Signallers.		A.A.S.C. Companies.	A.A.M.C.		A.A.V.C. Sections.		
						Companies.	Troops.	Sections.	Troops.		Field Ambulance.	Sanitary Section.

Soon after taking control of the defence organizations in Australia the Commonwealth military authorities realized the necessity for a small-arms factory; enquiries were instituted in 1907 and a factory was erected at Lithgow. The establishment of factories for the manufacture of cordite, harness, saddlery, leather accoutrements and, later on, of cloth and acetate of lime, followed. Since the outbreak of the European war interest in the subject had been stimulated, and in 1919 A. E. Leighton prepared a comprehensive report on the production of munitions in Australia, his proposals being calculated to meet all the estimated peace require-

ments of an army of 300,000 men. As a result of the reduction in the defence estimates in 1921 and the curtailment of the universal training system this scheme was modified, provision being made only for nucleus factories with an output capacity sufficient to train the staff in the technique of manufacture and to act as educational institutions for commercial establishments should rapid expansion become necessary.

The total military expenditure for the Commonwealth, and the strength of her land forces, are shown in the following table:—

Year.	Expenditure.	Strength of land forces.
	£	
1901–02	780,260	28,886
1902–03	600,625	25,604
1903–04	615,673	22,404
1904–05	728,810	19,880
1905–06	718,329	20,499
1906–07	780,023	21,948
1907–08	824,539	21,911
1908–09	783,330	22,631
1909–10	1,205,666	23,361
1910–11	1,540,992	23,509
1911–12	2,447,382	24,199
1912–13	2,685,689	23,696
1913–14	2,765,199	34,537
1914–15	12,709,017	45,645
1915–16	37,489,087	60,972
1916–17	57,099,080	74,127
1917–18	66,307,728	88,362
1918–19	95,823,485	122,186
1919–20	68,067,578	109,881
1920–21	59,435,628	102,665
1921–22	46,025,539	127,960
1922–23	33,351,849	37,156
1923–24	32,922,571	38,603
1924–25	32,182,149	38,889

Miller, Sir Denison Samuel King (1860-1923), born near Wollongong in New South Wales on 8 March 1860 and educated at the Deniliquin public school where his father was headmaster, in 1876 entered the employ of the Bank of New South Wales and during 36 years' service rose to be chief metropolitan inspector. In 1912, the Commonwealth government being in need of a governor for its newly established Commonwealth Bank (q.v.), Denison Miller was recommended by Russell French (q.v.) for the position, and on 1 June of that year received the appointment. At that moment the bank had no capital, and its only assets were a loan of £10,000 from the government and the knowledge that the Commonwealth was at its back. By June 1914 its resources had risen to about 9¾ millions sterling; the enormous financial transactions of the Commonwealth during the war were carried out by it under Denison Miller's guidance, and in 1922 its assets amounted to 126½ millions. Entrusted with powers not given to any other individual since Australia attained responsible government, Miller never shirked responsibility; his work was incessant, his travels throughout Australia were wide and many, and his decisions (which were prompt, imaginative, and optimistic) of the highest importance to his country's welfare. When he died suddenly on 6 June 1923, the loss was deplored as whole-heartedly by those who had opposed the establishment of the bank as by its strongest supporters. 'Starting,' wrote one of these critics, 'with nothing but Australia's credit, Sir Denison Miller built securely within the framework of the existing economic order, upsetting nothing essentially good, and by constructive work silencing the destructive criticism that surrounded the birth of the Commonwealth Bank. . . .Sir Denison Miller was not only a big banker, but one of the biggest of Australians. His leadership in banking and in Australian development cannot be assessed in money terms.' (K.C.M.G., 1920.)

Millet. See Sorghum and Millet.

Milletia, a large genus of the family Leguminosae, consisting of trees, shrubs, or climbing plants found chiefly in the warmer regions of Asia and Africa. Three species are endemic in Australia, all being ornamental woody climbers with purple flowers. *M. megastigma* (at one time believed to be a tree) extends from northern New South Wales far into coastal

M. megastigma.

Queensland; *M. Maideniana* is also found in Queensland scrubs, but does not come farther south than Port Macquarie in New South Wales; *M. pilipes* is confined to Queensland. *Milletia* is closely related to the *Wistaria* of our gardens (differing only in the pod), and is sometimes known as native wistaria. In the northern brush forests the plants climb and festoon the loftiest trees. They are occasionally found in cultivation in warm districts as far south as Sydney.

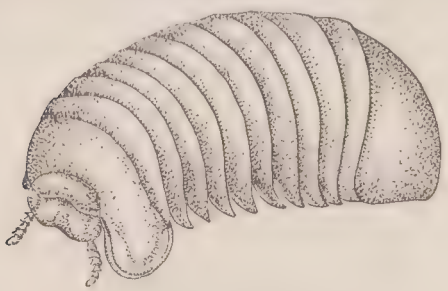
Millipedes, the vernacular name of a class (Diplopoda) of arthropods formerly combined with centipedes (q.v.) in the obsolete order Myriapoda, but now—for reasons mentioned under Centipedes—separated from them. Millipedes are long cylindrical animals with a varying number of horny segments, of which the first four or five bear one pair of legs each, and the rest two pairs. Along their sides are situated a number of 'stink-glands,' from which they can emit an unpleasant odour. In Australia about 21 genera, with 60 species, have been found. The commonest and most conspicuous belong to the family Juloidae; they vary in length from one to ten inches (the larger forms occurring in tropical forests), and are often brightly coloured. Of nocturnal habits, they live under stones, debris, or the bark of trees, and are often seen at rest coiled in a spiral. Their movements are slow, the motion of their short and slender legs being somewhat undula-

tory. Their food consists chiefly, if not entirely, of vegetable matter, frequently the roots of plants. *Spirobellus rainbowi*, from New South Wales, is about two inches long, black with

Dinematocricus falcatus
(three-fourths natural size).

yellow markings. *Dinematocricus falcatus*, a Queensland species, is four inches long, and of a chestnut-brown colour.

The pill-millipedes—so called from their habit of rolling themselves into a ball—belong to the family Zephronidae, species of which also occur in Africa, India, New Zealand, and elsewhere. Their body has 13 segments, of which the sec-



Cyliosoma penrithensis
(one-and-a-half times natural size).

ond and the last are greatly enlarged. In *Cyliosoma penrithensis*, which is about 1½ in. long and ⅝ in. broad, the male is olive-chestnut in colour, darker on the margin of the segments; the female is muddy brown.

The family Cambalidae has four peculiar genera which are indigenous to Western Australia, occurring also in Polynesia, India, and Madagascar. The Polydesmidae—with a cylindrical body of few segments, each having a keel or lobe on its upper surface—are represented by several genera and species. The Polyzoniidae, small worm-like forms with reduced appendages and sucking mouth, are represented by the genera *Orsilochus* and *Siphonotus*. Among Australian members of the allied group Symphyla there is at least one species of *Scutigerella*; this resembles a small centipede both in appearance and movement, and has 12 segments, with a pair of parapodia on each as well as the legs.

See Brolemann in *Records of the Australian Museum*, 1912-13. W.J.R.

Mineralogy. The mineralogy of Australia has usually been studied in connection with the development of her mineral wealth, and its records are to be found principally in the publications of the departments of mines of the different States; comparatively little has been contributed by private workers, and few collections have been formed. It follows that little attention has been given to crystallography, or to the silicates; at the more important mining centres (particularly at Broken Hill) very many specimens of great rarity or beauty must have gone to the smelters and been lost to science. We owe the specimens that have been preserved at Broken Hill mostly to the fact that publicans were willing to give for them a moderate payment in kind. It will be most convenient, therefore, to discuss the subject from the standpoint of mining.

All the important ores and minerals of the base metals, and many of the gemstones, are represented in Australia. Of gold there have been recorded more than 1300 nuggets, ranging from lumps of 20 ounces to the 'Welcome Stranger'—the largest mass of native gold yet found in the world—which yielded 2284 oz. of pure metal (see GOLD, DISCOVERY OF). From the Kalgoorlie goldfield have come the tellurides of gold, silver, and mercury—calaverite, petzite, sylvanite, coloradoite. Native gold is distributed very widely, and has been found associated with many of the ores of the base metals, but crystals are seldom found. Equally varied are the crystalline and other rocks in which it occurs. These are discussed under GOLD.

Definite minerals of which *silver* (q.v.) is the base have not been found to any great extent, except at Broken Hill, and at Yerranderie, west of Camden in New South Wales. The main Broken Hill lode produced in the oxidized zone much native silver, embolite, and iodyrite, and the near-by Consols mine yielded dyscrasite in fine crystalline masses, as well as pyrargyrite and other antimonial compounds of silver. Ruby silver (proustite) ores have been found scantily in the Armidale district of New South Wales and elsewhere. Naumannite (selenide of silver) is reported from near Cloncurry in Queensland. At Broken Hill spongy masses of embolite of great beauty were obtained, and kaolin veined with sulphur-yellow iodyrite or emerald-green embolite yielded fine specimens.

Copper (q.v.) has been mined in many places on a considerable scale, but few minerals of that metal have been recorded, other than those common enough to be used as ores. Beautiful arborescent and other forms of native copper occurred in the upper levels of the Broken Hill lode. Burra Burra in South Australia produced malachite suitable for cutting, and fine crystalline groups came from Peak Downs in Queensland, and from Cobar and Mount Hope in New South Wales. Good crystals of chalcopyrite and tetrahedrite have been found at a deep level of the Mount Lyell mine in Tasmania. Iodide of copper (marshite), a beautiful salmon-pink mineral, is found at Broken Hill, and is not known elsewhere in the world.

Among *lead* minerals (see SILVER), the great variety of superb masses of cerussite found in the Broken Hill lode are particularly noteworthy; arrow-headed twins and delicately reticulated groups of acicular crystals were found in abundance, but suffered much from extreme brittleness. With cerussite, anglesite was often associated. Beautiful satiny specimens came also from Dundas in Tasmania. Altaite has been recorded from Queensland, and a tungstate and molybdate of lead, which appears to be a new mineral, has been described from Chillagoe in Queensland.

Probably the finest crocoite ever seen, in beautiful groups and long pencil-like terminated crystals, was obtained at Dundas. Pyromorphite of various colours and forms was abundant at Broken Hill, and good specimens are known elsewhere. Broken Hill also yielded several varieties of stolzite, and good wulfenite. Stolzite is found also at Westonia in Western Australia.

Oxidized *zinc* (q.v.) minerals are little known,

but blende is a common ore in many metalliferous mines, and is of great industrial importance. Crystallized blende is very rare. Little crystals of zinc carbonate, thickly coating stalactites of cerussite and of manganese oxide, were of common occurrence in the upper levels of the Broken Hill lode. Crystallized gahnite is not uncommon in the schists of the Broken Hill district, and also in the lode itself.

Manganese oxides are widely distributed, but very few analyses have been made. Many of them are certainly psilomelane, but pyrolusite is known. The principal commercial deposits appear to be at Woocalla near Pernatty in South Australia, and near Gladstone in Queensland. Rhodonite is a very important constituent of the Broken Hill lode. Beautiful crystals are found occasionally, and masses of pure mineral are quite common, but these are not suitable for ornamental work. Rose-pink rhodochrosite is found there in vugs.

The more common ores of *iron* (q.v.)—hematite, magnetite, and limonite—are found in quantity in many places, but siderite is known only as a constituent of the gangue of metalliferous lodes. Vivianite and other less common iron-minerals have rarely been recorded, and no doubt search would reveal many more.

Antimony (q.v.) is widely distributed as stibnite, and very fine crystalline groups have been found at Hillgrove and Taylor's Arm in New South Wales. Cervantite, native antimony, and jamesonite are known.

Bismuth (q.v.) ores, both native and sulphide, have been mined to some extent in several States, principally in the granite areas of New South Wales and Queensland. Masses of native bismuth weighing several pounds occurred in the Kingsgate mines in New South Wales. Tetradymite has been recorded in small quantity, and at Mount Shamrock in Queensland and Whipstick in New South Wales the rare telluride joseite. Cosalite and allied lead-bismuth-silver sulphides are known, as is maldonite.

Molybdenite (see MOLYBDENUM) is widely distributed in many granite areas, often associated with bismuth; Queensland and New South Wales have produced what are probably the finest specimens yet seen in the world, including masses of pure mineral weighing hundredweights, and groups of perfect crystals, often of large size. The mines at Deepwater in New South Wales have yielded molybdenite in delicate crystals half an inch long. Ilsemannite and powellite are reported from Queensland, and the latter from Western Australia also.

Ores of *tungsten* (q.v.) have been mined in many places. Scheelite crystals of large size seem to have been numerous in northern Queensland, and were also found at Hillgrove in New South Wales. At King Island off Tasmania it is associated with garnet; it has also been found mixed with stibnite. The so-called cuproscheelite is known. Wolfram (using the term in a broad sense) is the most important ore. Very few analyses have been made, but wolframite, ferberite, and hübnerite all appear to be represented. Well-shaped crystals occurred in quantity at Torrington in New South Wales, but very few have been preserved. Association with cassiterite is not uncommon.

Cinnabar has been recorded from several places in Queensland and New South Wales, and several attempts have been made to work it commercially. In alluvial form it occurs at Cudgegong in New South Wales. Mercurial tetrahedrite was found in the cinnabar mine at Pulganbar in New South Wales, where also masses of pure cinnabar were found at the surface, but none in the mine.

Nickel ores and minerals are scarce. Pentlandite, with its variety heazlewoodite, is recorded from Dundas in Tasmania, and noumeaite from Bingara in New South Wales, both in small quantities. Nickeliferous pyrrhotite occurs in considerable quantity at Dundas. Important bodies of smaltite are being worked (1925) south of Cloncurry in Queensland. Erythrite occurred there, and an association with scheelite was noticed. Cobaltiferous wad has been worked to a small extent at Port Macquarie in New South Wales. A new sulph-antimonide of cobalt, characterized by very distinct cubic crystals, was described from Broken Hill under the name of willyamite.

With regard to *tin* (q.v.), cassiterite is distributed very widely in Queensland, New South Wales, and Western Australia, in both lode and alluvial deposits, more particularly in granitic areas. Large nuggets of pure mineral were found in the alluvial drifts, and fine crystals and crystalline groups were formerly obtainable. 'Resin,' 'ruby,' 'wood,' and several other varieties, including specimens suitable for cutting, and others of a creamy colour, have all been found. Stannite occurs at several places, notably at the Oonah mine in Tasmania and at Howell in New South Wales. Native tin has been reported, but confirmation is needed. Tantalite and stibio-tantalite are associated with the stream tin at Greenbushes in Western Australia. Common associates of cassiterite in granite are beryl and topaz, and, in some cases, wolfram.

No bauxite suitable for the manufacture of *aluminium* under present conditions is known, but laterite approximating thereto occurs in quantity in Western Australia, and also in New South Wales.

Alluvial *platinum* (q.v.), associated with gold, is worked near Fifield in New South Wales. Small nuggets have been found, the largest authenticated weighing nearly 28 dwt. Small cubic crystals are known. Platinum in small quantities is a constant constituent of the heavy sands of northern New South Wales beaches. Appreciable quantities of platinum and other platinoid metals have been detected by assay in the ore of the Walhalla gold-mine in Victoria, and also in decomposed serpentine in the Darling Range near Broken Hill.

Osmiridium (q.v.) is worked in the Savage and Adams river districts of Tasmania; principally in detritus, but also in sound serpentine. Nuggets and crystalline masses, up to 2 oz. in weight, are found occasionally.

Minerals of the *rare earths*, monazite, gadolinite, euxenite, fergusonite, xenotime, have been recorded, more particularly from Western Australia. *Monazite* is widely distributed, both in alluvial deposits and *in situ*, but is not common in large quantities, and the thoria content seems to be always low. Mineral containing five per cent thoria has been reported from Moolyella in Western Australia, and from the Northern Territory. Very fine autunnite and torbernite occur at Mount Painter in South Australia, and a complex *uranium-lead* mineral containing helium has been named pilbarite after the district in Western Australia where it was found. At Radium Hill, Olary (South Australia), carnotite has been mined and a small quantity of *radium* salt extracted (see RADIUM AND ORES). The carnotite at Olary is associated with *titanium* min-

erals, among which a new species, davidite, has been described. Mackintoshite and thorogummite have been found at Wodgina in Western Australia.

Vanadium minerals are scarce, but the metal is widespread in Western Australia in small quantities in clays and laterites. Roscoelite occurs in the Kalgoorlie mines. Carnotite has been mentioned already. Pucherite and vanadinite exist at North Coolgardie and in the Gregory Range (W.A.) respectively. *Tantalite* (and stibio-tantalite) is worked commercially in Western Australia and could be obtained in large quantity if required. A tetragonal form has been described under the name tapiolite. Amblygonite is known in the Northern Territory, in Western Australia, and near Broken Hill, and could be supplied in commercial quantities. Spodumene occurs at Ravensthorpe in Western Australia. *Rutile* has been mined at Blumberg, and is also known elsewhere in South Australia. Sphene from the Northern Territory is another possible source of titanium, and ilmenite is common. Chromite is mined in some of the serpentine areas of New South Wales, but is not of the highest quality. Arsenopyrite is common in the metalliferous mining districts, and a deposit of lollingite is worked (1925) at Delungra in New South Wales.

The commoner rock-forming *silicates* are widely distributed. *Quartz* crystals of large size and varied habit are associated with ores of tungsten, etc., in 'pipe' formations. Twined and double-ended crystals can be obtained, as can also rock-crystal and clear, smoky quartz. Baveno twins of orthoclase are found at Tingha, and a green variety is a constituent of pegmatite in the Broken Hill lode. Albite characterizes some pegmatites in Western Australia. Leucite is a constituent of some basalt flows in New South Wales, and nepheline-bearing tinguaites and syenites are known there and in Victoria. *Muscovite* in sheets of large size, suitable for industrial use, occurs in pegmatite in the Macdonnell Ranges and in Western Australia. From Coolgardie comes a beautiful pink lithium-bearing *mica*, giving an exceptionally clear quasi-uniaxial interference-figure. Lithia biotite is associated with wolfram at Torrington in New South Wales. Masses of *olivine* are included in the ejectamenta of an old volcano at Mount Gambier in South Australia, and a few stones suitable for cutting have been procured at Toowoomba, and in Victoria. Axinite, in lilac-coloured crystal aggregates, constitutes rock-masses in western Tasmania, from which district comes also pretty lilac-coloured stichtite—an oxide and carbonate of magnesium and chromium. Schorl is very common in granite areas.

Zeolites are found in abundance and variety at the basalt quarries near Melbourne, phacolite being especially characteristic. In many other quarries good zeolites are found occasionally, but are little known. Mention may be made of red stilbite from the Liverpool Range in New South Wales, and of prehnite from Prospect, near Sydney.

Amphibole *asbestos* (q.v.) is found in many places. Chrysolite asbestos of very fine quality occurs at Pilbara and Nullagine in Western Australia, but is too far from rail-head to be worked vigorously at present. In Tasmania and New South Wales chrysolite suitable for cement building-sheets has been mined to some extent, but the comparative poverty of the deposits made profitable working impossible. In South Australia the blue crocidolite variety can be had.

Gypsum (q.v.) and *salt* occupy the basins of desiccated lakes in South and Western Australia in large quantity, and important industries are developed (see SALT). In Yorke Peninsula gypsum is raised close to the coast, and is supplied to the plaster and cement industries of the eastern States. There is also much gypsum of moderate quality in Western Victoria and New South Wales. The mineral *selenite* occupied a large cavity in the Mount Elliott copper-mine near Cloncurry, and crystals up to 10 feet in length were obtained. Fine specimens containing moving bubbles have been found. From this cavity came a unique specimen of water-clear selenite, containing between the cleavage-planes the wing of an archaic variety of locust. *Chalcedony* 'waterstones' were common on the Richmond River at one time, and remarkable enhydros with polyhedral outline used to be found at Beechworth in Victoria.

Magnesite (q.v.) of excellent quality occurs in large quantities in several States. *Limestone* of the very finest quality is widespread, often in places very accessible and handy to coal. A very important 'Portland' cement industry is firmly established in New South Wales, and a beginning has been made in other States. Pottery and brick *clays* are plentiful. Pigment clays, more particularly ochres, have been worked to a small extent in South Australia, near Launceston in Tasmania, and elsewhere. Silica sands, suitable for glass and other manufactures, have been proved to exist (see KING, JAMES), but not much is known about them. *Alunite* (q.v.) is mined regularly at Bulladelah in New South Wales, and is known also in South Australia. *Barytes* (q.v.) of excellent quality is supplied from Noarlunga and other localities in South Australia, and also from Tasmania, for the industries of the capital cities. *Fluorite* of metallurgical grade has been mined at Emuford in northern Queensland and at several localities in New South Wales, and pure mineral suitable for enamels can be obtained near Emmaville in New South Wales. Dolomite for furnace-linings is quarried at Lue in New South Wales. Diatomite is obtainable in several localities, and deposits of exceptional texture and purity of colour exist in Victoria. Schists containing workable proportions of *flake-graphite* occur on Eyre Peninsula and in Western Australia, and a low-grade amorphous variety is known at Maryborough in Queensland and elsewhere. Jarosite in workable quantity occurs at Anglesea in Victoria (where it is being utilized) and also in Western Australia. *Phosphate* rock of medium grade is known in South and Western Australia, and has been worked to some extent; but for superphosphate manufacture recourse must be had to the cheap and high-grade mineral from Nauru (q.v.). *Fuller's earth* is worked at Boggabri in New South Wales and is supplied for the industries of the capital cities. Crude *emery* of moderate quality has been discovered in Western Australia and New South Wales.

Good bituminous *coal* (q.v.) is available in the eastern States and in Western Australia. Enormous deposits of lignite await the demands of the future, this being particularly the case in the southern States, where supplies of true coal are less satisfactory. What is perhaps the finest deposit of brown coal in the world, of low ash and water content, is now being developed at Yallourn (q.v.), and will soon be supplying power to a great part of Victoria. The possi-

bilities of the Leigh's Creek deposit in South Australia are being investigated; other deposits are known along the Bight and in Western Australia. In the Dawson River district of Queensland there are extensive beds of semi-anthracite. *Oil-shale* (perhaps better described as torbanite) has been worked to some extent in New South Wales, and large deposits of high-grade mineral, with easy access to rail, will be available when economic conditions are favourable. True oil-shales exist in very large quantity in northern Tasmania, and are known also in Queensland, but no oil has been discovered in Australia (see OIL). *Coorongite* is a rubber-like combustible scum forming at flood-level on certain creeks in South Australia. Its origin has been ascribed variously to vegetation or to the existence of petroleum. Lumps of asphaltum are picked up on the beaches along the whole coast of southern Australia. Its origin is unknown, but apparently it comes from beneath the sea.

Opal (q.v.) is Australia's principal gemstone, in particular black opal from Lightning Ridge in New South Wales. At Whitecliffs in New South Wales remarkable replacements of fossil organisms by opal were found, some of which are of exceptional beauty. Among these organisms were reptilian skeletons, a considerable variety of mollusca, and crinoids, all belonging to the Cretaceous period. Opalized bivalve molluscs have been found in considerable quantity at the Stuart Range opal-field in South Australia, and a few at Lightning Ridge. Of more normal character is the Ballina (New South Wales) opal, which takes the form of infillings of the vesicles of a volcanic rock. *Sapphire* is found at many places in eastern Australia, particularly in the tin wash-dirts. There are two productive fields, Anakie and Inverell. At Inverell several pieces of basalt in which sapphire was embedded were found in the wash, but the original source is not known. *Diamonds* (q.v.) are found in alluvium in eastern Australia, and in conglomerate at Nullagine in Western Australia. Of great scientific interest is a diamond-bearing dolerite dyke at Oakey Creek near Copeton in New South Wales. A 28-carat stone was found at Mount Werong (N.S.W.), but Australian stones are usually small. Bort occurs occasionally. As in the case of sapphire, the source of the diamonds is unknown. Coloured *tourmaline*, suitable for cutting, was at one time procured on Kangaroo Island, and the zeuxite variety is found at Mount Bischoff. *Garnet* of gem quality (formerly regarded as ruby) exists in the Macdonnell Ranges, and crystals of great size and regular shape form part of the gangue of the Broken Hill lode, nor are fine specimens of spessartite and of pyrope rare at Broken Hill. *Zircon* of workable quality is associated with many alluvial deposits and with sapphire at the Anakie and Inverell fields; it also occurs in north-western Tasmania, and on the northern beaches of New South Wales large quantities of pure zircon sand associated with ilmenite could be separated by magnetic concentration. *Topaz* and *beryl* are associated with tin and wolfram in both alluvial and lode deposits, and material suitable for cutting is found occasionally. At Mount Bischoff interesting radial groups of topaz (replacements of quartz-porphyry) were at one time obtainable. *Emeralds* have been found at Poona in Western Australia, and were worked commercially for a time at Emmaville in New South Wales. Aluminium phosphate approximating to turquoise is found at a number of places on the eastern coast, from Rockhampton down, and stones of good colour were obtained in the King Valley in Victoria. Chrysoprase (Comet Vale, Western Australia), agate (northern Queensland), and chiastolite (Bimbowrie, South Australia) call for mention. *Ruby* is very scarce. *Pleonaste*, which is cut occasionally as a setting for brilliants, is found in various gem-sands. Mention may be made of struvite from the Skipton caves in Victoria, of ammonium chloride and ammonium sulphate from guano caves at Wooltana in South Australia, and minerrite from Jenolan Caves; also of gearksutite from Gingin in Western Australia.

A *Bibliography of Australian Mineralogy*, by Charles Anderson, complete to 1916, is published as *Mineral Resources No. 22*, by the Geological Survey of New South Wales. G.W.C.

Miners, perching birds belonging to the genera *Myzantha* and *Manorhina* of the honey-eaters (Meliphagidae) see HONEY-EATERS. The Australian miners were apparently so named by early settlers in Tasmania from the resemblance of their noisy calls to those of the birds known as 'mina' or 'myna' in India (Hindustani *maina*). These are members of the starling family (q.v.) and one of them, the common Indian Myna (*Acridotheres tristis*), has since been introduced into Australia. For the Australian bird the spelling 'miner' seems to have priority; probably the exact spelling of the Indian name was not known to the early settlers. The suggestion that the name was given because the birds were common in the mining districts is obviously incorrect, since Backhouse found it in use in 1832 many years before gold was discovered.

The Noisy Miner (*Myzantha garrula*) is very common in eastern Australia and Tasmania, and is usually called 'soldier-bird' or 'micky.' It is gray, with black-and-whitish markings on the head, the bill and a bare patch round the eye being yellow. It is commonly found in small

Noisy Miner or Soldier-bird (*length* 10 *in.*).

flocks, feeding on the honey of flowers or on fruits; it is very pugnacious, driving away other species when they approach, and constantly uttering its noisy cries. A rather darker bird, the Dusky Miner (*M. obscura*), takes its place in south-western Australia, extending eastwards to north-western Victoria; its habits and notes are very similar. The Yellow-throated Miner (*M. flavigula*) is found in inland districts throughout the continent.

The Bell Miner or Green Bell-bird (*Manorhina melanophrys*), though closely allied in structure, differs markedly from the miners in habits. It is a shy bird, generally frequenting the banks of streams or rivers that run through dense eucalypt forests, and is found in such localities from Vic-

toria to Queensland. Its coloration is dull green, yellowish beneath, with a yellow beak. Its note is a bell-like 'tink,' but, as it is almost always found in small parties, and each individual seems to strike a different note, the combined effect is wonderfully like that of a distant chime of bells. Kendall's 'silver-voiced bellbirds, the darlings of daytime,' belong to this species. W.B.A.

Mining. In its infancy, Australian mining was confined to the winning of gold from shallow alluvial deposits, usually by inexperienced men (e.g. runaway sailors); anyone was a miner who could handle a pick and shovel, and special knowledge was considered unnecessary. The persistence of this notion is partly responsible for the widespread belief that mining is a form of gambling: any business conducted by inexperienced men is a form of gambling. At first comparatively small rich deposits were sought; but large low-grade deposits are now more favoured, because in the long run they pay better.

Mining is divided into three stages, prospecting, developing, and exploitation. Prospecting is generally done by tracing ore from gullies to its source by 'loaming,' 'costeaning' or trenching, tunnels, and shafts. Loaming is taking samples of the soil at right angles to the supposed course of the lode; costeaning or trenching is done first of all at right angles to the supposed course of the lode; when the lode is found, trenching may be continued along its strike. Alluvial ground is tested by boring or sinking shafts, or by a tunnel in cases where there is a covering of basalt on the side of a hill. Sometimes a shaft is sunk and a cross-cut driven to intersect a lead, but the favourite method is boring, because no trouble in pumping is experienced, and a number of bores can be put down for less than the cost of one shaft. In sinking a shaft for lode mining the questions to be considered are these: Is there a suitable approach to the shaft? What is its relation to the rich portions of the lode? Is there a good dump-site for ore and mullock? If the angle of the lode approaches the vertical, what is the depth at which it should be cut? When the lode is wide, it is better to sink on the footwall side, so that the shaft will not be damaged if the workings should collapse.

Ores: Ores of the following metals have been won, or are being won, in Australia, some being mined specially, others obtained as by-products: antimony, arsenic, bismuth, chromium, cobalt, copper, gold, iridium, iron, lead, manganese, mercury, molybdenum, nickel, osmium, platinum, radium, selenium, silver, tantalium, telurium, tin, wolfram, and zinc. In addition, the following are mined: alunite, asbestos, barytes, building-stones (sandstones, slates, marbles, granites, basalt, etc.), clay (fire, brick, pottery), coal, diatomaceous earth, fluorspar, fullers earth, graphite, gypsum, kerosene shale, limestone, magnesite, mica, monozite, ochres, phosphates, precious and semi-precious stones (diamonds, emeralds, garnets, opals, sapphires, turquoise), salt, talc, water (artesian and mineral). See MINERALOGY.

Methods of mining in Australia are as follows:

Dry Blowing.—Dry blowing is resorted to in places where water is scarce. There are many machines designed for this purpose, but the principle is the same in all. Gravel is placed on a shaking screen; the undersize passes into a hopper and thence on to a tray forming the inclined top of a wind-box: this tray consists of a perforated zinc sheet with 'riffles' fixed across it. The wind-box rests on single or double bellows worked by a hand-staff; in order not to disturb the angle of the perforated sheet of zinc, only the bottom of the bellows moves. The wind-box communicates with the bellows by means of valves, and the whole is mounted on a wheelbarrow. The concentrate from the dry blower is still further concentrated by winnowing. This is done—in a spot where there is a strong current of air—by pouring the concentrate from a dish held head-high into another on the ground, so that the wind blows the lighter particles away. When sufficiently reduced in bulk, the concentrate is cleaned by separating the worthless material from the gold with a magnet and blowing it away with the breath. A good deal of gold is lost by this crude method, but local conditions are often such that there is no choice. Winnowing is also used in arid districts for testing ground, just as one would pan-off a 'prospect' in places where there is water.

Panning-off.—For panning-off stanniferous gravel a tinned dish should be employed, since the dark cassiterite is more easily seen against a light surface; unfortunately the tin soon wears off. For panning-off gold, a black iron dish is preferable, since the gold shows up better on it. The dishes are circular in form and are made in three sizes, namely of 17, 15, and 12 in. diameter at the top, and, respectively, 11, 10, and 7½ in. at the bottom. The sides are 4-in. deep. The largest size is the one most used, and 120 dishfuls go to the load. Dishes have a groove round them near the edge to prevent heavy material from sliding out when the dish is tilted, and there is a second groove half-way round and parallel to the upper groove to serve as an additional safeguard. For testing alluvial, the dirt is piled up in the dish and placed under water. The coarse pebbles are then rubbed between the hands to wash off any gold adhering to them, and, when clean, are raked out with the fingers. The gravel having been removed, the finer material is agitated by the hands to make the heavy particles sink to the bottom; then the lighter material is lapped off with water. The dish is righted, the contents swilled round, care being taken not to jerk, for fear the heavy material should become again mixed with the tailings. The dish is then tilted and given a side-to-side motion so as to collect the values at one end; then the lighter material is lapped off as before. These operations are repeated till there is only a small residue. To separate the heavy valuable material from the heavy valueless, the proper way to lap off is by moving a small quantity of water from side to side in the dish, leaving a tail of gold behind; or a little clean water may be dribbled through the fingers on to one end of the residues in order to wash the worthless material down. A dish used for panning-off should never be employed for cooking, since grease is liable to cause a loss of gold.

Ground-sluicing.—This method is used for shallow alluvial deposits, and may also be adopted if the bed-rock is hard and irregular; otherwise sluice-boxes fitted with various forms of riffles are employed. The sluice-box is made in sections of 12-ft., each section being given a grade of 6 inches. When a shallow deposit is to be sluiced, a ditch is cut through the gravel, and water is led on to the ground. The banks of the ditch are then gradually broken

down and washed through the sluice-box, where the gold or tin is caught. Large stones that find their way into the box are removed with a fork, and thrown on one side. Where water is available only at certain times of the year, all preparations should be made during the dry season so as to be ready for the rainy season.

Hydraulicking.—The unit of water in Australia, for mining purposes, is known as a 'sluice-head.' It varies in quantity in different States, but for most of them a 'box-sluice head' means approximately 29 cub. ft. water per minute, and a 'ground-sluice head' 172 cub. ft. per minute. Hydraulicking may be done in a small claim with a low pressure of water coming through a canvas pipe with the neck of a soda-water bottle for a nozzle.

A more elaborate plant may entail miles of ditches (or 'races') flumes, and pipes, with hydraulic 'giants' for undercutting the face and washing the fallen material into the sluice-boxes. This method is employed for high faces of alluvial gold or tin situated above the natural drainage-level. Though the original outlay may be great, subsequent working expenses will be low. The ditches, flumes, and pipes which convey water to the pressure-box are collectively known as the 'head-race.' The pressure-box is a box in which leaves, sand, etc. are strained off and settled, and which allows the water to be sufficiently above the intake to prevent air from being sucked in. From the pressure-box the water is conveyed to the nozzles by a feed-pipe or a number of pipes. The various sections of such a pipe are generally put together stove-pipe fashion, and are kept from coming apart by wire, which passes over hooks riveted near the ends of each section. Air-valves are inserted at suitable places to allow air to escape when filling the pipe, or so that air may be admitted, thus preventing the formation of a vacuum, which might cause the pipe to collapse if all the water should get out in consequence of a breakage. A ditch cut in the bed-rock is called a 'sluice.' At a distance of a few yards from the face, wooden sluice-boxes in 12-ft. lengths are placed in the sluice; obstructions are laid on the bottom of these boxes so as to retain the gold and also the quicksilver which is put in at the top end to catch the gold. These obstructions are known as 'riffles,' and may consist of shingle of approximately the same size and carefully placed by hand, the upper end of the shingle inclining slightly down-stream: or they may be wooden blocks, round in section as when cut from trees: iron rails fastened together in rafts of a weight convenient to handle may be placed either crosswise or lengthwise in the box; angle-iron is used in a similar manner: also cast-iron Venetian riffles.

As the face recedes, the sluice-box is brought forward, and the ditch at the end of the sluice-box becomes the 'tail-race.' The grade of the sluice is regulated by the nature of the gravel. If there are too many large pieces to be forked out, the coarse pieces are passed over a grizzley to a hopper, from which they are trucked away, while the fine material drops between the bars and goes to an undercurrent. One giant nozzle undercuts the 'face,' and, when the face falls, another giant with a larger nozzle washes the gravel into the sluice and thence to the sluice-box. The sluice-boxes are generally cleaned up once a week or fortnight, and the tail-race once or twice a year. When the deposit is below the natural drainage-level of the country, a hydraulic elevator is required. This is an uptake pipe, generally about 15-in. in diameter, up which a 2 to 2¾-in. nozzle conveys water at high pressure, and, playing up the 15 in. pipe, takes up with it the water and gravel from the sump. If there is plenty of water with sufficient head it works effectively.

Hydraulic Dredging.—This, which is really not dredging at all, but hydraulicking with the help of a centrifugal pump, has been much used for re-working old alluvial diggings. The artificial head created by the pump makes a lengthy head-race unnecessary, and alluvial can be worked below the natural drainage-level, since all the machinery is on a barge which, in case of flooding, will float. The gravel is raised by another centrifugal pump to the sluice-boxes situated on the natural surface, so that, in case of flooding, the gold will not be lost. The outlay for plant is not great, and one great advantage is that the cost can be calculated beforehand. There need be little preliminary work, and, if the ground is worth working, it should pay from the start; moreover, the plant being comparatively inexpensive, it can be used for working small isolated deposits where it would not pay to bring in a long head-race. As in ordinary hydraulicking, the bottom can be thoroughly cleaned up. Work is started by making an excavation about 50-ft. square and 6-ft. deep, and the barge is built on the bank of this excavation and launched. The barge is from 35 to 45 ft. long (not counting a 4-ft. tail-board, which is sometimes added), 30-ft. wide, and 4-ft. deep. It draws 3-ft. of water when loaded. The machinery consists of a marine type of boiler 20-ft. long and 7-ft. in diameter, fitted with from 38 to 60 4-in. tubes, and with a working pressure of from 120 to 125 lb. per square inch. The main engine is of from 130 to 170 i.h.p. There are a duplex feed-pump, an air-pump, a condenser, and a steam bilge-pump. The pump is a 12-in. centrifugal, delivering water to a 4-in. nozzle at a pressure of from 60 to 70-lb. per square inch. The pump which raises the gravel to the sluice-box is a 10-in. centrifugal, and there should be a washing-down pump also. The sluice-boxes are from 80 to 120-ft. long, 4-ft. 6-in. wide, and 12-in. deep. The head of the sluice-box is supported on trestles erected on the barge; the rest stands on trestles built on the ground. Most plants have an electric-lighting plant, for which there must be a special engine. By the time the machinery is placed on board, another excavation, alongside the first, has been sunk down to the bed-rock, and a level bed has been made on it for the barge to rest upon. When everything is ready, the excavation is flooded and the barge floated in; then the pump is set to work to empty the excavation, and the barge settles down on the bed-logs. A 20-ft. sump-hole is sunk in the rock near the barge, and is protected by a grating to catch such boulders as may escape the forks of the sluicers. As hydraulicking progresses, races with a grade of 1 in 24 are cut in the bed-rock from the face to the sump. The main race is cut up the centre of the paddock and branch races meet it at suitable angles. At first the tailings have to be stacked on the surface, but when once the barge has been moved up, a brush-and-sand tailings-dam is formed, and the tailings are deposited behind it. The water is drained out of the tailings-dam through a pipe into the lowest part of the new paddock, and can be used over and over again; by this means about two-thirds of the water used is recovered. A paddock consists of

an area of from 1 to 2½ acres. When the working-face gets so far away as to necessitate the cutting of a deeper race to obtain a suitable grade to the sump, from 3 to 4 ft. of water is allowed to accumulate in the paddock, the sluice-boxes on the barge are disconnected from those on the bank, the barge is floated to its new position (where bed-logs have been previously laid), and a new sump is sunk.

Bucket-dredging.—This method is used when in or over the gravel—such as wash in the bed of a watercourse or a river-flat—there is too much water for the employment of either hydraulic sluicing or hydraulic dredging. The gravel is turned over, and though when disturbed it is not so compact as the original deposit, fresh material tending to silt up watercourses is not brought into them as is the case with hydraulic sluicing. The first bucket-dredge in Australia built for gold-dredging was C. L. Garland's, used on the Macquarie River, New South Wales, in 1899. Bucket-dredging is a subject too large to be dealt with here. The best books on it are Earl's *Gold Dredging* (London, 1913) and Prelini's *Dredges and Dredging* (London, 1912).

Open-cut.—The upper portion of wide lodes is removed by this method. Sometimes it is adopted from the beginning, as in the case of Mount Lyell, Tasmania, where the open-cut is 1000-ft. by 800-ft. on the surface and 487-ft. deep; in other cases rich portions of a lode, due to secondary enrichment, are first worked by underground methods and the rest of the lode is subsequently removed by open-cut. This was done at the Broken Hill Proprietary mine, New South Wales, and at Mount Morgan, Queensland. The ideal open-cut is one that goes as deep as the natural drainage of the country, and that does not necessitate the removal, when forming a batter, of more rock than can be immediately used as filling. Double handling is thus obviated, and the ore, if it has to be blended with sulphides for smelting purposes, can be worked in the proper proportion.

With the open-cut there is no fear of missing rich patches of ore; the men are easily supervised; in the daytime the light is natural and the air good; there is no loss of ore in pillars; there is no expense for timbering or filling; there is plenty of room for working, and one can generally lay out larger benches or stopes than are possible underground; besides which all holes are down-holes. On the other hand, work may be hung up by inclement weather, large quantities of waste rock may have to be removed, and a large area of land is rendered valueless.

The brown coal deposit at Yallourn (q.v.), Victoria, is worked by open-cut. At Mount Morgan, Queensland, the soft overburden is removed by steam shovels. For working headings the Whitaker shovel is employed, because the whole platform revolves and the dipper or bucket can therefore empty into buckets at the rear. For sidings where a parallel set of rails can

Principal deposits of copper ore.

be laid for the trucks, the Bucyrus type of shovel was preferred.

In the Iron Knob district, South Australia, the ore is all obtained by open-cuts. The faces vary in height up to 180-ft. and are kept at an angle of 20 deg. from the vertical. Holes are drilled 20-ft. deep with high speed air hammer-drills, spaced about 35-ft. apart laterally, and arranged to have about 30-ft. burden. These holes are 'bulled' or chambered with 50 per cent gelignite, the final blast being made with 25 per cent ligdyn. The holes are fired in groups of from four to ten, the object being to fetch down about 20,000 tons with each blast. The shattered material has to be still further broken up by poppers before it can be loaded into quarry waggons.

Deep Lead Mining.—Shallow alluvial deposits worked in the early days of mining in Victoria had not infrequently to be followed under flows of basalt, and, since gravel holds water like a sponge, the country had to be drained before the wash could be worked. In other cases molten lava, which naturally sought the low-lying land, covered the ancient watercourses, and when it solidified, being harder than the adjoining sedimentary rocks, it better withstood the action of the weather. Basalt protecting the gravel on the higher ground was reached by tunnels driven into the side of the hill.

There are two methods used in Victoria for laying out the workings of deep leads; one (known as the 'down-country' method) is used in the southern districts; the other (the 'up-country' method) is used farther north. The up-country method originated at Chiltern in Victoria.

In the *down-country method* a shaft is sunk clear of the alluvial (the position and depth having been previously determined by bore-holes) and, when this is well below the deepest part of the wash, a cross-cut is driven underneath, and from this a main or reef drive is cut in the supposed direction of the ancient watercourse. The cross-cut is made high, so as to allow room for the water which will probably be tapped to flow under the footboards. The cross-cut and main drive are made as level as possible (consistently with drainage towards the shaft), so that, in case of a rush of water, the mouth of the horizontal passage will not be sealed up so quickly as it would be had it been given a steeper grade. This gives the miners a better chance of escaping, and also (since the down-stream drive has a grade in the opposite direction to that of the original river) it does not intersect the wash so soon as if it were steeper. Every now and again branches are driven at right angles to the main drive, and in the roof of these bore-holes are put up. These not only serve to drain the wash, but also give information of any change in direction of the old watercourse, and so enable the direction of the main drive to be changed accordingly. At suitable distances apart, so-called 'balance shafts' are raised, but not in such a way as

Principal deposits of iron and manganese.

to reach the wash; from the top of a balance shaft an intermediate drive is driven. The balance shaft consists of two cage compartments and a ladderway. A cage is fastened to each end of a rope, which has two or three turns round a pulley overhead, and a brake is attached to the side of the pulley, regulating the rate at which the full cage descends and raises the empty cage. An intermediate level, started in the bed-rock or 'reef,' is connected by occasional jump-ups (i.e. chutes for sending down the wash) with a drive made in the wash, and there is a ladderway for the men. The grade of the bed of the ancient watercourse, being more or less irregular, is not suitable for long trucking, and the wash is therefore sent down to the intermediate drive as soon as possible; the upkeep of a wash drive being greater than that of a drive in rock, sections of it are abandoned as soon as they are worked out. The down-stream intermediate drive, having a grade in the opposite direction to the wash drive, eventually penetrates it, and then the intermediate becomes the wash drive and the main drive takes the place of the intermediate.

In the *up-country method* a shaft is sunk to below the wash-dirt; a cross-cut is driven, from which various drives branch off up and down in the supposed direction of the deepest portion of the deposit; and drainage bores are put up into the wash. Higher up the shaft another cross-cut is driven over the one below, at such a depth from the surface that it will intersect the lowest portion of the wash. Before it cuts the wash, however, it branches off up and down stream, forming what is known as 'reef drives.' Branches at right angles are driven from the reef drives right across the deposit, and parallel wash drives are driven up and down stream at right angles to and connecting these, thus dividing the wash into blocks; the wash is dropped down chutes to the main reef drive. The upper drive helps to ventilate, serves for bringing in timber, and in case of a rush of water gives men a better chance of escaping.

Two methods of extracting the wash are known respectively as 'blocking' and 'panelling.' At one time the wash met with in drives was tested by panning, and, if payable gold was shown, extraction would be continued, but if no gold was shown the block was left. Later on it was proved better to extract all the wash systematically, since testing the sides of a drive in this rough manner furnishes no true criterion of the block. To prepare the wash for blocking or panelling, cross-drives, 150-ft. apart, are made on each side of the main wash-dirt drive, and from the sides of these cross-drives, at intervals of 32-ft., truck roads are driven; a strip 16-ft. wide is thus left on each side of them.

Panelling is used when the pay dirt is less than 4-ft. thick. The mine is opened up into blocks, and the wash-dirt is taken out in strips 4-ft. 6-in. wide. Where the wash is less than 2-ft. 6-in. thick, it is necessary to take out enough rock to give a working-space of 2-ft. 6-in. While the wash is being extracted, the roof is supported by laths resting on panelling props—pieces of round or split timber from 2½ to 3 inches thick. The truck roads are made lower than the panel, so that the dirt can be easily shovelled into trucks. Panelling is paid for at per square fathom of 36-sq. ft., irrespective of the height.

Blocking is used when the ground taken out is 4-ft. thick or over, or when it is too loose for panelling. Cross-cuts are driven on both sides of the main wash-dirt drive and at right angles to it, from 200 to 300 ft. apart. These cross-drives are connected every 46-ft. by blocking drives. Allowing 6-ft. for the width of the blocking drive, a solid block or pillar 40-ft. wide will be left. This pillar is divided lengthwise down the middle by an imaginary line. Two miners and a trucker per shift make up a party, and each miner works up to the imaginary line, or 20-ft. from the blocking drives on either side of the pillar, beginning at the end nearest the worked-out ground. All the blocks in a section are worked simultaneously, so as to keep the face even right across the lead; the ground overhead is allowed to fall in after the pay dirt has been extracted. At Chiltern, Victoria, the miners extracted 2-ft. of wash and 1½-ft. reef bottom. Blocking strips are 8-ft. wide, and, as the timber is only required to support the roof for a short time, light props are used, placed about 4-ft. apart; on top of these are caps, generally 8-ft. long; if the roof is crumbly, back laths are also necessary. Blocking is done by contract at so much per running foot, the width being always 8-ft.

Underhand Stoping.—This method is used to a very limited extent, and that mostly in small mines in which it is desired to win ore underfoot without the expense of opening up a lower level.

Overhand Stoping.—Most underground extraction of ores is done by some form of overhand stoping, such as breast, flat-back, rill, shrinkage, etc.

Breast stoping is used for certain narrow lodes. The breast may be parallel to the strike when the underlay is flat, or at right angles to it if the underlay is steep. In the former case it is sometimes known as a 'long-wall' stope, and in the latter as 'incline cut and fill,' since the face is inclined in one direction and the subsequent filling in the opposite direction. This method can be used only if the walls will stand till the excavation can be filled. No passes are required, since the ore falls down the incline, but it is rather dangerous for men when others are working above them.

Flat-back method.—An advantage of this method is that, when there are horizontal joints, slabs of ore may be shot down, and in falling they break up. Filling is generally brought up sufficiently high to enable the miners to stand on it when breaking down ore, and the necessity of rigging up a staging is thus avoided.

Shrinkage method.—This is somewhat similar to the flat-back method, but instead of the worked-out space being filled with waste as mining proceeds, broken ore is allowed to remain behind. This method has been used at the Great Boulder Perseverance, Lake View Consols, Great Fingall, and other mines in Western Australia.

A combination of flat-back and shrinkage methods is sometimes employed if the ground will permit, as at the Great Cobar mine in New South Wales. For some 20 to 30 ft. the ore is broken as for the shrinkage system: the sill floor and leading stope are taken out together, the face being on a slope, so that the miners can reach the roof. When each stope reaches the required height, all the ore is drawn, and the space is filled with mullock. One objection to this method is that a stope may remain out of commission for a long time while the ore is being withdrawn and the space mullocked up; in certain cases this might cause a considerable variation in the production of a mine. A shrink-

age-stope from which the ore has been drawn may be allowed to fall in, or it may be filled up.

Rill or Sloping Stope method.—In this case a winze is sunk and a leading stope started on each side of it at an angle slightly flatter than the angle of repose of broken ore; the ore is removed, ore-passes are built where required, and mullock sent down the winze comes to rest at the angle of repose and is allowed to fill up to within from 2 to 4 ft. of the roof. Planks are laid on the filling to prevent ore from becoming mixed with it and getting lost or contaminated, and another slice of 5-ft. to 8-ft. ore is broken down. When this ore has been sent down passes, the planks are taken up, more filling is run in, and the same routine repeated. Matters are so arranged that ore-extraction is taking place on one side of the winze while filling is being done on the other. When the stope is nearly worked out, it is usual to sink a subsidiary winze in the triangular block of ore left, through which filling can be dropped.

If a lode is very wide, as at Mount Morgan, it may be divided up lengthwise into strips about 50-ft. wide, each strip being stoped independently of the other, except that each is kept in advance of the next. A rearing of poles is placed between the unworked ore and the filling of the different strips, so that ore and filling shall not become mixed.

Ore-passes.—These are built up from below as the ore is extracted, and should be so situated that ore can be easily sent down them to the level below. They may be rectangular or circular in cross-section, and may be single or double. In wide lodes double passes are used, for the reason that a single pass is likely to become worn out before the stope is completed. With a double pass, one compartment is used for sending down the ore, and the other as a ladderway. Rectangular passes are logged up, and their tops are kept a little higher than the filling, so as to prevent mullock from falling into them and contaminating the ore. The ladder compartment should be built up high, so that ore shall not be shovelled into it by mistake and possibly injure someone travelling up or down.

At Broken Hill, circular passes both of wood and iron have been designed. These, being smooth inside, do not offer the same resistance as logs, and consequently do not wear so quickly; hence there is no necessity to build double passes. As the upper portion of a pass has less wear and tear than the lower, the wooden passes are made in sections of different thickness. Those of the lower 30-ft. are 4-ft. in diameter with staves 10-in. thick, while those of the top 30-ft. are 3-ft. in diameter with 4-in. to 5-in. thick staves: the staves, which are from 4 to 8 ft. long, are bound together with fencing-wire, with two strands at the top and two at the bottom, tightened round two short pins on the Spanish windlass principle.

A pass may hang up if it is crooked or at too flat an angle, if drills fall down and get stuck crosswise, if the ore is sticky, or the lumps too big. Sometimes the difficulty can be overcome from the ladderway, or it may be reached by digging down from above, in which case the miner should have a rope attached to him, for fear the ore may suddenly run. It is very dangerous to try to free the block by poking from below, and this should not be allowed. Perhaps the best method is to use a 'cannon' designed at Moonta, South Australia, and now used in other Australian mines. It consists of a mild steel cylinder 12-in. long and 4-in. in diameter; a 2-in. hole is bored down its length for 10-in., and ½-in. from the bottom of this hole there is drilled a touch-hole for a fuse. The cylinder is further strengthened by three wrought iron rings 1-in. thick. A full charge is from 10 to 14 oz. of blasting powder—nitroglycerine compounds are not allowed, since they would burst the metal. Some earth is tamped on the top of the powder, and sometimes on this again, iron punchings of from ⅛ to ¼-in. diameter by ½ to ⅝-in. thick. The cannon is placed on the bottom of the pass and fired by a fuse. It is the shock rather than the punchings that shifts the ore.

Coal (q.v.) is worked by some variety of 'bord and pillar' or 'longwall.' The bord and pillar method is the one more generally used and consists in working out oblong chambers from 4 to 12 yds. wide, leaving pillars of coal between to support the roof for the time being: this is known as 'working in the solid;' when the pillars are being extracted it is known as 'broken working.' In the early days it was usual to rob the pillars till they could no longer stand the overhead weight and therefore crushed; nowadays, after a few bords are driven, the pillars are extracted as soon as possible, before they get weakened by standing. In this way much less coal is wasted.

In the Maitland district of New South Wales, where the coal is liable to spontaneous combustion, the workings are laid out on the panel system (i.e. a barrier pillar is left round an area of coal which is left intact except for absolutely necessary passages). The coal in each panel is worked as a separate mine, so that, should a fire break out in one panel, it can be sealed off and work can be continued in other panels without hindrance. This system is used at Lambton B. Colliery, where each panel is 23½ chains square with 16-yd. barrier pillars; at Hebburn Colliery, where the panels are 20 chains square and the barrier pillars 33-yds. wide; also at East Greta Colliery and Stanford Merthyr Colliery, all in New South Wales.

The long-wall system is used for thin seams such as those at the Sydney Harbour Colliery, Stockton Borehole Colliery, and, in part, at North Bulli and Mount Kembla, all in New South Wales, and in the Victorian State Coal Mine, Wonthaggi. More coal is won with the long-wall method than with the bord and pillar.

Largest Australian Mine Shafts. Most Australian colliery shafts are circular in cross section and lined with brick where necessary, the colonial bond being used, i.e. three rows of stretchers to one of headers. At the Bulli colliery there is a concrete-lined shaft 16-ft. in diameter. Cast-iron tubing of the English pattern has been used in some of the collieries so as to cut off waterbearing strata—for example, at the Balmain colliery (Sydney) and the Lambton B and Delta collieries (near Newcastle, N.S.W.); but the two last named are now closed. The deepest pair of colliery shafts are at the Balmain colliery; they are 18-ft. in diameter and 2900-ft. deep. The next deepest are at the Metropolitan colliery, Helensburgh, N.S.W., being 15-ft. in diameter and 1100-ft. deep. Metal mines in Australia are mostly oblong in cross section and are supported by timber. The two deepest are the Victoria Consolidated (over 4600-ft.) and the New Chum (over 4100-ft.) both gold-mines at Bendigo, Victoria. The usual size of shafts for Australian gold-mines is 12-ft. by 4-ft., divided into two hoisting compartments of 3-ft. 6-in. by 4-ft. inside timbers, and a pump and ladderway 4-ft. 6-in. by 4-ft.

F.D.P.

Ministries, Federal, Colonial, and State, since the establishment of responsible government.

COMMONWEALTH.

KEY TO OFFICE.

1. Prime Minister.
2. Minister for External Affairs.
3. Attorney-general.
4. Minister for Home Affairs.
5. Treasurer.
6. Minister for Trade and Customs.
7. Minister for Defence.
8. Postmaster-general.
9. Vice-president of the Executive Council.
10. Minister for the Navy.
11. Minister for Repatriation.
12. Minister for Works and Railways.
13. Minister for Home and Territories.
14. Minister for Health.
15. Minister for Markets and Migration.
16. Honorary Minister (sometimes called Assistant Minister, or Minister without Portfolio).

Mints. See CURRENCY.

Mirbelia, a genus of the family Leguminosae, consisting of shrubs with yellow, purple, red, or blue flowers, endemic in Australia. The pod is oval or oblong, divided longitudinally into 2 cells by a wall projecting into the cavity

M. dilatata.

from the lower side. *M. dilatata,* a western species, has showy clusters of blue flowers, and triangular leaves which have given it the name of 'wedge-leaved' mirbelia. A coloured drawing of this plant, made from plants grown in 1823 at Kew Gardens near London, is given in Edwards' *Botanical Register. M. grandiflora,* a spreading shrub, bears a profusion of large yellow flowers.

Missions. This article is concerned with the missionary activities of the Christian communions in Australia—except the Roman Catholic, which are dealt with in the article on that Church.

Church Missionary Society.—Earliest in the Australian field was the Church of England. As far back as 1825 an auxiliary of the Church Missionary Society for Africa and the East, the headquarters of which were in London, was established in Sydney; it had for its objects the evangelization of the aborigines and the collection of funds for the parent society's operations in other parts of the world. Governor Brisbane became its patron, and Samuel Marsden its president. Marsden had in 1814 established the Church Missionary Society in New Zealand, and it was he who initiated the auxiliary in Sydney. Missionaries to the aborigines were sent from England, but the auxiliary was responsible for their maintenance. In 1832 J. C. Handt and W. Watson began work in the Wellington valley in New South Wales, and were joined in 1837 by James Günther; a station was also founded at Blacktown near Parramatta. But the nomadic habits of the aborigines, the hostility between them and the settlers, and friction with the colonial government, enforced a temporary abandonment of the work.

In 1892, at the instance of the auxiliary, Eugene Stock of the C.M.S. London and Robert Warren Stewart of the Fukien mission in China visited New South Wales; as a result the auxiliary was merged in an association, still linked with the parent society but empowered to select, train, and maintain Australian missionaries in any fields occupied by the parent society, and to undertake independent missions if it so desired. Similar associations were founded in Victoria, Tasmania, and South Australia, and in 1916 all four were federated as 'The Church Missionary Society of Australia and Tasmania.' Hussey Burgh Macartney (q.v.) in Victoria had for upwards of 30 years maintained a number of missionaries in India and China; after 1892 this work was, at his request, taken over by the Church Missionary Association of Victoria.' Since 1892 130 missionaries—including married clergy, medical men, and educational and industrial missionaries—have been sent to Church Missionary Society stations in India, Africa, China, Japan, Palestine, Persia, and Turkey in Asia.

In 1906 work among the aborigines was resumed at the Roper River in the Northern Territory, and other stations have since been established on Groot Eylandt and (at the instigation of the Commonwealth government) at Oenpelli near Darwin. In 1925 over 100 missionaries were at work, and the expenditure was over £35,000 annually. For many years the society has also carried on work among Chinese immigrants in New South Wales; this work, however, has been much lessened, because many Chinese residents of long standing have returned to their own country and new immigrants are not now admitted into the Commonwealth from China.

Testimony has been borne by the parent society to the admirable work done by Australian missionaries. Maynard Pain and John Bateman in Old Cairo and H. D. Matthews in Foochow, China, have rendered skilful medical service. Amy Wilkinson, wife of George Wilkinson who was formerly in charge of the Church Missionary Society hospital in Foochow—and herself a great-granddaughter of Samuel Marsden—has carried out work among the blind in China. Archdeacon E. W. Doulton and Canon Burns served efficiently in the Tanganyika territory and Kenya Colony respectively. Nellie and Topsey Saunders of Melbourne and Annie Gordon of Queensland were devoted missionaries and lost their lives at the time of the massacre at Hwa Sang in Fukien. Archdeacon Barnett has done distinguished evangelistic and scholastic work in China. A. R. Blacket was a pioneer to Persia from Victoria.

In 1916 a determination of the general synod of the Church of England in Australia (referred to below) provided that the Church Missionary Society of Australia and Tasmania should be recognized as an agency under the Australian

board of missions, with power of unfettered action in any diocese of Australia.

Australian Board of Missions.—George Augustus Selwyn (q.v.), the first bishop of New Zealand, in 1850 founded the Australasian board of missions as the department of the local Churches specially concerned with missions to the aborigines of Australia and New Zealand, to aliens residing in those countries, and to the heathen of the South Pacific. The board also took over the Australasian work of the Society for the Propagation of the Gospel, including the Melanesian mission. When a general synod of Australia was created in 1872, the board was reconstituted as the Australian board of missions. Its greatest work has been the foundation and extension of the New Guinea mission, which was founded by order of the general synod when Papua became a dependency of Australia. The work of Albert Maclaren and Copland King in this mission is specially notable, though Maclaren soon died of malaria; Copland King, after long service—which included much valuable work on translations into the Papuan languages—died in Sydney on 5 October 1918. Another early worker was Samuel Tomlinson, one of the six men recorded in the history of missionary achievement as having translated the whole Bible into a foreign language.

In 1898 Montagu John Stone-Wigg, then sub-dean of Brisbane, was consecrated bishop of New Guinea, and his generosity and enthusiasm placed the mission's finances on a sound footing. Stone-Wigg retired in 1908, and was succeeded by Gerald Sharp in 1910; he in 1921 was translated to Brisbane, and was succeeded in New Guinea by Henry Newton in 1922. The mission area allotted to the Church of England comprises a strip of the north-east coast between Cape Ducie and the boundary of the Mandated Territory, with its hinterland as far back as the main range. The coastal districts are effectively served, and some of the hinterland has been touched. The staff in 1926 consisted of about 40 missionaries, three native priests, four native deacons, a few Melanesians, and a large body of Papuan teachers.

The Australian board of missions devotes much attention to the aborigines. Of its stations Yarrabah was the first (1892); others are situated on the Mitchell (1905), Roper, Forrest, and Lockhart rivers. The success of Yarrabah has induced governments, both State and Federal, to give more assistance to missionary work. The first mission at the Forrest River station failed, partly for lack of adequate support, partly because in an attack by natives its head, Harold Hale, was severely wounded and rendered incapable of further service. A second attempt in 1913 under E. R. Gribble was more successful; Gribble had already for 17 years been in charge of Yarrabah, which his father had managed before him. The Lockhart River station was established at the request of the Queensland government to prevent the ill-treatment of natives of Cape York Peninsula by low-class whites and Japanese; a white layman is in charge, assisted by a native priest from Torres Straits and three other aborigines. The chaplain at Yarrabah regularly visits the Palm Island settlement, Barambah, and Taroom. The board of missions also maintains a missionary at the Western Australian aboriginal settlement about 100 miles from Perth, and has lent to the Aborigines' Friends Association of South Australia two nurses who help in the religious work at Point Pearce and Point McLeay. Further, when the London Missionary Society was compelled to abandon missionary work in Torres Straits, and asked the bishop of Carpentaria to take charge of it, the board took responsibility for the finances; four missionaries are at work among a community of 2000 Christian natives, two of whom have been ordained priests and two deacons. The board shares responsibility for work in the diocese of Polynesia with the New Zealand Anglican board of missions, and supports two missionaries (a teacher and a nurse). Nor does it neglect the white residents of these territories; in Papua it has two chaplains (at Port Moresby and Samarai), and in the Mandated Territory one, with headquarters at Rabaul (see MANDATED TERRITORY and PAPUA).

Presbyterian Church of Australia.—In 1850 William Ridley (q.v.) migrated to New South Wales and in 1852-6 worked as a missionary among the aborigines of northern New South Wales. In 1862 J. G. Paton (q.v.), who since 1858 had been working on Tanna in the New Hebrides, roused the Presbyterians of New South Wales and Victoria to contribute £3000 towards the cost of a vessel (the *Dayspring*) for the New Hebrides mission; after a visit to Scotland he went back in 1866 to Aniwa, John Geddes in 1864 was stationed on Erromango, Daniel Macdonald (a Victorian) in 1872 on Efate, R. M. Fraser and J. B. Weir on Epi, and F. H. L. Paton (afterwards foreign mission secretary for Victoria) on Tanna. In the New Hebrides there are now 16,000 native Christians, of whom 300 are trained teachers; the teachers' training institute is on Santo. The Church in New South Wales is responsible for stations on Malu and western Santo, the Victorian Church for those at Vila, Malekula, and Epi (at Vila there is a hospital); this Church also, in conjunction with the John G. Paton Mission, supports missionaries at Erromango, Tanna, Lenakel, Paama, and Hog Harbour on Santo.

Since the Presbyterians of the various colonies federated, a board of missions has been formed to control mission work among the Australian aborigines; this work is chiefly carried on in Queensland, and since 1923 is supervised by the Church in that State. The Western Australian station at Port George IV, however, is still directly under the board, as the local Church is not strong enough to take it over. The Queensland stations are at Mapoon, Weipa, Aurukun, and Mornington Island. With regard to other missions the assembly of each State conducts its own operations and reports to the general assembly through the board of missions. Victoria, South Australia, and Tasmania have workers in the New Hebrides and Korea, and Queensland shares the Korean work. The principal and most extensive foreign work of the Victorian Church is in Korea. It has stations at Fusanchin, Masan, Chinju, Tong Yung, Kuchang and Pyeng Yang. At all these stations there are considerable numbers of married and single missionaries, several of whom are members of the medical profession. New South Wales, besides its New Hebridean stations, has workers in southern India with headquarters at Sholingarh. New South Wales and Victoria carry on work among the local Chinese residents through two ordained Chinese ministers, John Young Wai in Sydney and J. Long Wai in Melbourne.

Australian Inland Mission.—This mission,

which is a branch of the Presbyterian Church, was initiated in 1912. It is all-Australian in character, has adopted as its motto 'For Christ and the Continent,' and ministers to settlers of every creed, or of none. Its aim is to provide a nursing-home within 100 miles of every settlement in the vast interior, and it has established them at Alice Springs, Beltana, Birdsville, Hall's Creek, Lake Grace, Marble Bar, Marranboy, Oodnadatta, Port Hedland, and Victoria River Downs. Further, it has missionary centres in central Australia, and at Broome, Gascoyne, Katherine, and Pilbara, and in western Queensland—and, with other Christian bodies, maintains a missionary on the east-west railway, with headquarters at Tarcoola; it intends to establish motor-patrols, each manned by two ministers of the Gospel, and to use the aeroplane as the most effective way of dealing with cases of sickness. The mission's field of operation aggregates 2,000,000 square miles.

Methodist Missionary Society of Australasia.—In 1855 the Australasian Methodist Church took over from the parent society in England responsibility for missions established in Tonga (1822), Samoa (1834), Fiji (1835), and Rotuma (1839). Since taking over these stations the Australian Methodist Church has also entered the following fields—New Britain (1875), Papua (1891), Solomon Islands (1902), Fiji inland mission (1902), and United Province, India (1909), and is at work among the aborigines of the Northern Territory. In 1925 the missionary stations were carried on by 41 ordained European missionaries, 29 missionary sisters, 10 lay missionaries, 128 ordained native missionaries, 321 native catechists, 1005 native teachers, and 4184 local preachers. They had 43,586 church members and 160,588 attendants at public worship. Their income amounted to £88,096, exclusive of a considerable sum raised by the natives themselves. Tonga and Samoa are entirely self-supporting, paying for their European missionaries in addition to all other expenses. Native work in Fiji is self-supporting, but the European missionaries there are paid by the Australian Church.

Australian Board of Baptist Foreign Missions.—Before 1864 Baptists in Australia sent occasional contributions to the Baptist Missionary Society of Great Britain and Ireland. On 10 November 1864 the first Australian Baptist Missionary Society was constituted at Adelaide, mainly through the efforts of Silas Mead. The first contributions were sent for the support of workers and missionaries in India appointed by the British society, but in 1882 Ellie Arnold and Marie Gilbert went to India as the first Australian Baptist missionaries. The return of the former to Australia in 1884 (owing to ill-health) led to the formation of societies in all the States save Western Australia, which came in 15 years later; for a time Tasmania was affiliated to South Australia. Up to 1912 these societies initiated and managed their own work, but in August 1911 a convention of State unions held in Melbourne suggested a basis of federation, and on 5 February 1912 this was adopted at Adelaide and a board of missions was constituted representing five States (Queensland sent delegates six months later). The area served comprises the districts of Faridpur, Goalundo, Sirajganj, Mymensingh, Comilla, and Noakhali; these had previously been served by the societies of South Australia, Western Australia, Tasmania, Victoria, New South Wales, and Queensland respectively.

Kanaka Mission in Queensland.—During the seventies and eighties of last century large numbers of South Sea islanders were enticed to leave their homes for work in the Queensland cane-fields. At one time as many as 10,000 'kanakas' were working on the plantations, many of them near Bundaberg on the properties of Horace and Ernest Young. These brothers and their families organized classes in which their kanakas were taught Christianity, and the evangelistic movement quickly spread to other fields in the colony; soon the sugar-growing districts were covered by 11 mission-centres with 19 missionaries, there was a weekly average attendance of 7000 at the Bible-classes, and 2500 islanders were converted and baptized. More than 100 of these taught (unpaid) under the supervision of the missionaries, and for nine years the Christian kanakas supported a European missionary in China. Ultimately they were all repatriated (see IMMIGRATION RESTRICTION) and in 1906 the mission in Queensland came to an end; but several workers followed them to their island homes, and in 1907 the *South Sea Evangelical Mission* was established under the superintendence of Florence Young, assisted by councils of advice in Sydney, Melbourne, and the leading cities of New Zealand. Since the initiation of the mission five workers have died and 27 (four of them natives) have been retired for health or other reasons. In 1925 25 missionaries were at work, with Northcote Deck, who has been out since 1908, in charge. Four mission ships and two launches are employed.

Congregational Church.—The London Missionary Society was one of the earliest to start work in the South Pacific. Many of its missionaries were men of heroic type—John Williams, martyred at Erromango, James Chalmers, martyred in Papua, and W. G. Lawes. In 1883 the Australian auxiliaries were allowed to examine and recommend candidates without reference to London; in 1926 they have 12 men and 23 women in the field, among them A. W. Brough (Kaiser-I-Hind medal) and H. W. Whyte, who have rendered distinguished service in southern India. Howard Smith and Dr. E. J. Stuckey in China, and H. P. Schlencker and Harold Short in Papua are worthy successors of Macfarlane, Murray, Lawes, and Chalmers.

When in 1919 the Australian auxiliaries entered into more intimate relationship with the parent society, the control of the mission in Papua was handed over to an Australian committee, which also acts as an advisory board for the work in the South Pacific. The missionary ship *John Williams* is employed in maintaining communication between Sydney and the stations in the South Seas and Papua. Australian Congregational Churches contribute from £10,000 to £12,000 a year for the mission work now apportioned to them.

The *Australian Churches of Christ* began foreign mission work in 1889, and now have missions in India at Harda in the Central Provinces; at Baramati, Shrigonda, Diksal, Indapur, and Dhond in the Bombay Presidency; in China at Shanghai and at Hueilichow in Szechwan; and in the New Hebrides on Pentecost, Oba, and Maewo. They also have missions for Chinese at Sydney, Melbourne, Adelaide, and Perth. In 1925 they supported 28 missionaries, 200 native co-workers, 1250 day-scholars, and 175 orphans.

China Inland Mission.—The history of this mission is inseparable from the name of Hudson

Taylor, who founded it, organized its manifold ramifications, and remained its director for upwards of 50 years.

In the eighties seven leading athletes of the university of Cambridge resolved to devote their lives to missionary work in China—D. E. Hoste (now director of the China Inland Mission), Stanley P. Smith (formerly stroke of the Cambridge eight), W. W. Casells (subsequently bishop in Szechwan), C. T. Studd (who had played cricket for England against Australia), Montague Beauchamp (who had been a university oar), and C. P. and A. T. Polhill (the former an officer in the 2nd dragoon guards, and both of them prominent in cricket at Eton and Cambridge). The interest extended to Australia, and was accentuated by the fact that Hudson Taylor was appealing for an additional thousand missionaries for China. In 1890 the exertions of H. B. Macartney (already mentioned), C. H. Parsons, W. Lockhart Morton (a Presbyterian), and Alfred Bird (a Baptist) stimulated the formation of an Australian branch, which has since then sent to China 230 missionaries (92 men and 138 women). Parsons went to China, and an Australian council was formed to arrange for the reception and training of suitable candidates. The mission carries on its operations in the inland provinces, those on the coast being dealt with by other societies. In 1925 there were 116 Australian missionaries (43 men and 73 women) labouring in 14 provinces.

The *Sudan United Mission* was formed in London in 1902 to place a line of mission-stations from the Niger to the Nile in order to protect the pagan tribes from the Mohammedans, who press the acceptance of their tenets at the point of the sword. In 1911 Australia resolved to share in the work, and the first Australian missionaries settled at Melut on the Nile, 500 miles south of Khartoum, where they maintain an efficient hospital. At the request of the Anglo-Egyptian government five Australians have been sent to the Nuba Mountains province (150 miles from Melut) and two to Abri; elementary and industrial schools have been opened, school primers have been prepared, and some of the Gospels have been translated into the native language. C.R.W.

Seventh-day Adventists.—The Australasian Union conference of Seventh-day Adventists is carrying on missionary effort among the natives in 12 mission-areas of the Pacific islands. Their 136 missionaries are now at work in the following groups: Society Islands, Fiji, New Hebrides, Solomon Islands, Cook Islands, Samoa, Tonga, and in Papua, Niue, Lord Howe, and Norfolk islands. At Monamona, near Cairns in northern Queensland, and in the Kempsey district of New South Wales, there are aboriginal mission-stations, and the young natives connected with these have shown themselves bright and susceptible to educational influences.

145 Sabbath-schools have been organized in the islands, with a regular membership of 4460, and large numbers who attend irregularly. Daily instruction is given to 1276 pupils in 61 schools, in which are employed 65 teachers. Seventy-two church buildings have been erected in the various islands, and the enrolment of baptized adult church members now numbers 1430. Several Young People's Missionary Volunteer societies have been organized, the membership being 768. The total funds raised by the Australasian conference during the year 1925 for island missions amounted to £44,470.

The missionaries of the denomination receive their training at the Australasian Missionary College, Cooranbong, New South Wales, where in addition to their theological studies they are instructed in practical branches of industry, such as carpentry, painting, engineering, tinsmithing, farming, baking, domestic science, etc. Recognizing the dire need of medical missionaries in the islands, Seventh-day Adventists have provided a training-school for such missionaries at the Sydney Sanitarium, Wahroonga. A three-years course of theoretical and practical instruction is given by the three resident medical practitioners, assisted by qualified and experienced nurses. During their course, Bible instruction is imparted to the trainees by the chaplain of the institution. Although the expense is heavy, it is fully warranted by the excellent results achieved. A.W.A.

Mistletoe-bird, a small, arboreal, perching bird (*Dicaeum hirundinaceum*) the only representative in Australia of a genus found throughout southern Asia and the Malay Archipelago, and belonging to the family Dicaeidae (flower-peckers). The male mistletoe-bird is brilliant blue-black above, with a bright red breast and another red patch under the tail; the female is duller above, and the only red beneath is a pale patch beneath the tail. The species is common throughout most parts of Australia, but does not occur in Tasmania. Owing to their habit of keeping to tree-tops the birds are comparatively rarely seen, except by those familiar with their

Mistletoe-bird (*length* 3½ *in.*).

lively notes. They feed largely on the berries of mistletoes (*Loranthus*), supplemented by insects, and are probably of much assistance in spreading these plants from tree to tree. The nest is perhaps the most beautiful constructed by any Australian bird, being a deep bag composed of white downy hairs (derived from the seed-vessels of various plants) suspended from a branch. The eggs are dull-white. W.B.A.

Mistletoes. See LORANTHUS.

Mitchell, DAVID SCOTT (1836-1907), only son of James Mitchell (q.v.), was born on 19 March 1836 in the surgeon's quarters at Sydney hospital; at the age of 16 he was admitted to the university of Sydney as one of its first 24 matriculants and one of the first seven scholars on its foundation (B.A., 1855; M.A., 1859). He was called to the bar in 1858 but, sensitive and retiring in disposition—lazy, too, he later confessed—he never practised. For the politics of the day, newly leavened with democracy, he had all the scorn of a cultured aristocrat, and took no interest in his father's business affairs beyond giving him occasional legal advice. In his youth he played cricket and was a good dancer; but his health was always precarious and shaped (if it did not determine) the course of his life. His interest was in literature, especially Elizabethan, and he was familiar also with the eighteenth century writers and the poets of the early 19th century. He himself wrote occasional verse, of no literary merit but interesting in so far as it substantiates the story of his affection for Emily Manning (see HERON, E. M.) whose 'clarion words' summoned him 'to mingle in the crush of life;' but she refused to marry him, and his sensitive pride took refuge behind a reserve that was hardened by the publicity occasioned by legal proceedings in connection with his father's will. About 1871 his friends endeavoured to bring him into the service of the State by offering him the attorney-generalship; but he was set in his ways, and declined. He sold his property in Cumberland-street and moved to Darlinghurst, where, remote from old associations, he began to gather what is now the greatest collection of Australiana in the world. His means, when once the Mitchell estates were freed of mortgage, were ample, and Australiana from all parts of the world streamed towards him. As a result books, pamphlets, diaries, manuscripts, autograph letters, portraits, views and pictures, broadsides and proclamations, log-books, maps and charts, coins and tokens and medals—the original material which alone can yield the secrets of Australian history—were stored in the overcrowded rooms of his house, which he never left except to visit the booksellers. He never allowed a rare thing to escape him; on the other hand all Australiana, rare or commonplace, were fish for his net. 'I must have the damned thing' he would say, 'in order to show that it is worthless.'

Until the nineties Mitchell seems to have made no plans for the eventual disposal of his collection. His cousin, Rose Scott (q.v.), who was one of his few regular visitors, and his old friend Dr. James Norton realized its value to Australia; and, urged by them, on 17 October 1898 he communicated to the trustees of the public library (of which Norton was president) his intention to bequeath it to them, together with an endowment, provided they were constituted a corporate body. His distrust of politicians prevented his bequeathing it to the State. He stipulated, however, that the government should provide suitable accommodation for the public library, preserve his collection intact in a separate wing or set of rooms to be known as the Mitchell Library, and make it freely available to students on conditions similar to those obtaining at the British Museum. In the following year an act was passed making the trustees a corporate body with perpetual succession, able to hold and administer any property bequeathed to them; such bequests were also exempted from stamp and probate duty. Thereupon Mitchell handed over the 10,000 volumes that made up his general library, and 50 pictures, as an earnest of his purpose—and, incidentally, to make more room for Australiana in his house in Darlinghurst-road. But the government was slow to comply with his conditions, being unwilling, it seems, to incur large expenditure in housing a library about which so much had been heard but so little was known, and the reputed value of which was said to be exaggerated. On 14 February 1901 Mitchell made a will bequeathing his collection to the trustees, together with an endowment of £20,000; being naturally resentful of the government's inaction, he added a proviso to the effect that it must be taken over and properly provided for within a year of his decease, the executors being empowered to grant an extension of time under certain conditions. The trustees and the public librarian, aware of his failing health, induced the government to reserve a site for a new public library—at first (in 1904) in the outer domain between the art gallery and St. Mary's cathedral, but in the following year in the present position, facing Macquarie-street and adjoining parliament-house. The erection of a library building was referred to the public works standing committee on 10 October 1905, before which the value of Mitchell's Australiana was proved by incontestable evidence; the necessary act was passed, plans were prepared by the state architect, W. L. Vernon, and on 11 September 1906 the foundation-stone of the Mitchell wing was laid by J. H. Carruthers, then premier, but for whose vigorous action the library might have been lost to the State. Mitchell refused an invitation to perform the ceremony, or even to be present. Satisfied that his conditions would be fulfilled and pleased to have perpetuated the family name, he increased the endowment to £70,000. The building was still under construction when he died on 24 July 1907; but from the window of the room in which he lay dying he could see its walls steadily rising.

When Mitchell died, 61,000 volumes, manuscripts, maps, views, portraits, etc., were taken over by the library trustees, packed and put into bank vaults until the building was ready to receive them; they were then gradually removed to it and the work of cataloguing was begun. In October 1909 Hugh Wright of the public library staff, was appointed Mitchell librarian under the control of the principal librarian. The official opening was on 8 March 1910. Since that time the collection has been greatly enriched by the judicious purchases made by the trustees.

Mitchell, JAMES (1792-1869), born in Fifeshire, Scotland, in 1792, entered the army medical department at the age of 18 (L.R.C.S., Edin., 1813), and had nine years' active service in Spain, America, the Netherlands, and the West Indies. On 22 June 1820 he was appointed assistant surgeon in the 48th regiment, then stationed in Sydney, and arrived in the colony by the *John Barry* on 7 November 1821. When the regiment was reduced in strength in 1822, he went on half-pay, and on 11 June 1823 was appointed to the colonial medical service and attached to Sydney hospital (then part of the convict establishment), of which he was given charge in 1825. In 1829 John Bowman, the principal surgeon, was appointed inspector of hospitals, and Mitchell was promoted surgeon. He built up an extensive private practice, and in 1833 resigned from the army—'I much regret the loss of your service to the Department'

wrote the director-general of the army medical department on 25 September.

Mitchell had many interests outside his medical work. In 1827 Allan Cunningham gave his name to a river (now the Namoi) 'as a compliment to the medical officer to whom I am so much indebted for the very valuable details of barometrical observations taken in Sydney during my absence on the journey.' As was customary, a grant of 2000 acres—which he selected at Burragorang—was made in his favour when he joined the colonial service, and during the thirties he also acquired, by grant and purchase, large landed interests chiefly in the Hunter River district, where his brothers-in-law, Robert and Helenus Scott, were landed proprietors. In 1836 he helped to form the Australian Gas Light Company of Sydney.

In 1836 the colonial medical service was reorganized and put under military regulations; this change was resented by the colonial surgeons, and the new chief, John Vaughan Thompson, did nothing to allay the hostility. From the outset he and Mitchell were at loggerheads, chiefly on questions of organization; in March 1837 Mitchell was temporarily suspended from office, and Bourke reprimanded him for insubordination. In September, when called upon to attend a flogging at the Hyde Park barracks—an unpleasant duty which for many years had devolved upon the assistant surgeon—Mitchell refused to obey, and was dismissed the service. His cause was supported by part of the local press and by influential friends, and he was allowed to produce evidence in his defence. Bourke, however, stood by his previous decision, and was supported on appeal by the colonial office—which at a later date, however, ordered Gipps to allow Mitchell to submit further evidence; Gipps 'in the interests of H.M. service' decided against a permanent reinstatement, but suggested that he might be reinstated for a day and allowed to resign. This was agreed to by the colonial office on 1 October 1841. Mitchell's defence is contained in a pamphlet, *Statement of the case of Jas. Mitchell Esq.* (1838). See HOSPITALS.

On retiring from the service, Mitchell pursued his medical work less vigorously, and after a while ceased to practise, but maintained his connection with the profession through the New South Wales medical board, of which he became a member in 1845 and president in 1852. In this capacity he was in 1853 appointed one of the official trustees of the Australian Museum; in 1855 he was nominated to the legislative council, and in 1856 and again in 1861 to the new council under responsible government. Business interests absorbed his energy to an increasing extent. He suffered financially from the failure in 1843-4 of the Bank of Australia (of which he was a director) losing all his properties except certain Hunter River land which was at the time considered valueless. When, however, the Australian Agricultural Company's coal monopoly ceased, he developed plans for working his coal-bearing land at Burwood (near Newcastle) and proposed to combine the smelting of copper and other ore with coal production. In May 1849 he was allowed to occupy for wharfage purposes vacant crown lands on the waterside at Newcastle, and in 1850 to construct a light line from his mine to the wharf through the Australian Agricultural Company's estate; in 1853 he organized the Newcastle Coal and Copper Company, gave it a long lease of his mines and other works at Burwood, and transferred to it all his acquired rights. About the same time he became one of the original proprietors of the Hunter River Railway Company, formed to construct a railroad from Newcastle to Maitland; the property of this company and of the Sydney Railway Company was taken over by the government in 1855. Mitchell also established an extensive woollen-factory at Stockton near Newcastle, but the venture was not a success.

In the early sixties the Newcastle Coal and Copper Company failed, and Mitchell had his Burwood property back on his hands. He proposed at first to establish a glass and porcelain factory, and was supported in this by W. E. Wolfskehl—a recent arrival in the colony—who represented himself to be a member of a banking family at Darmstadt in Germany. This project falling through, the two collaborated in establishing the Burwood and Newcastle Smelting Company, Mitchell having meanwhile become surety for Wolfskehl to the Bank of New South Wales for £15,000, which he was afterwards called upon to meet. It was proposed to obtain ore from the Currawang mine (near Goulburn) in which both acquired an interest. But after the Burwood works had been in operation for nine months (from September 1866 to May 1867) the Currawang mine proved a failure, and the works, unable to obtain supplies of ore, were temporarily closed. In November 1868 the Burwood engineer was sent to South Australia to procure supplies of ore and to establish a coal agency. Just then Mitchell's health suddenly failed, and he could no longer perform his many duties—he was president of a medical board, a legislative councillor, trustee of the museum, fellow of St. Paul's College, chairman of the Australian Gas Light Company, director of the Australian Mutual Provident Society, and the proprietor of estates (mortgaged in part to meet recent obligations) valued at £100,000. He died on 1 February 1869.

After his death it was found that he had, a month previously, made a will by which the management of his estates was left in the hands of Wolfskehl as sole executor, who was further authorized to mortgage them (to their full value, if necessary) to carry on the business enterprises which had already been undertaken. Mitchell's family produced a will made in 1841, and disputed the new will on the grounds of mental incapacity and undue influence. The resulting lawsuit, in which the attorney-general appeared for Wolfskehl, aroused great public interest, heightened by the court's order forbidding publication of the proceedings—an order which was rescinded shortly before the close of the trial. Judgment was in favour of the Mitchell family—an important decision, in view of the fact that it was from part of the proceeds of the estates in question that David Scott Mitchell (q.v.) purchased and endowed the Mitchell Library.

On 6 June 1860 Mitchell indicated by petition to the Lyon King of Arms in Scotland that, out of respect to his wife's family, he had assumed the surname of 'Scott' in addition to and before that of his own, and was now known by the name of James Scott-Mitchell; he desired a licence to bear and use such arms as might be indicative of his name, marriage, and station in life. The licence was granted on 6 October 1860, but he does not seem to have adopted the new surname for general use.

Mitchell, JAMES (1834-1914), the best known of a family of pioneer squatters remarkable alike for its ancestry and for its achievements in the pastoral development of the upper Murray valley.

The founder of the family in Australia was WILLIAM MITCHELL (1786-1837), an officer of the Kent militia who retired with the rank of captain and about 1811 migrated to New South Wales. In 1815 Macquarie granted him 200 acres at Upper Minto, of which he was probably already in occupation. Here he was neighbour to a French *emigré*, Gabriel Louis Marie Huon de Kerilleau—Kerillac and Kerrillian are variants of the name, and in 1822 its owner signed himself Killian. Gabriel had left France for personal, not political, reasons in 1789, joined Nepean's company of the New South Wales Corps under the name of Thomas Lewis, and reached Sydney in June 1790 (a less probable story makes him leave France in 1792 and enlist under the name of Louis Michel); by 1800 he had reverted to his own name, and in 1807 was discharged from the Corps by order of the colonial office, which had just discovered that he was related to a French bishop. In 1807-9 he was teaching French at Parramatta, and acted as tutor to John Macarthur's family; Bligh gave him land at Bankstown, and Paterson at Minto.

William Mitchell married Gabriel's daughter Elizabeth (named after Mrs. Macarthur), and the families lived on intimate terms both at Minto and (from 1825 onwards) in the Goulburn district near Bungonia, where Brisbane granted them land; Mitchell's estate was known as Brisbane Meadows and his friend's as Corrundaroo or Corrundunna. In 1837 William Mitchell was lost in the bush between Bungonia and the coast. In 1836 two of Gabriel's sons, Paul and Charles—who as far back as 1822 had dropped the territorial part of their name and were known as 'Huon'—took up on the Murray River a run which they named 'Wodonga;' in 1837 Charles took up Mungabareena run (on which the town of Albury now stands), and on William Mitchell's death handed it over to his sister, Mitchell's widow. This brought her four sons one after the other to the Murray district. Thomas Mitchell, the eldest, managed his mother's new station for 14 years, adding to it two more between the Kiewa River and Yackandandah; in 1852 he bought Tangambalanga on the Kiewa, sold it in 1874, and in 1875 settled down at Bringembrong near Welaregang on the upper Murray. Edward Mitchell, the second son, was for a long time left in charge at Brisbane Meadows, but in the end settled at Ellerslie near Albury. John Francis Huon Mitchell, the third, managed Mungabareena for his mother after Thomas left it, in later life moved to Ravensworth in Victoria, and in 1904 published a *Vocabulary of the Woradgery Language*. He died in 1923 at the age of 92.

James Mitchell, the fourth son, born at Brisbane Meadows in 1834, was educated at The King's School at Parramatta, and trained for a pastoral life by his brother Thomas at Mungabareena. In 1859 he took over Table Top (just north of Mungabareena) from his mother, who had bought it in 1851. This station had for many years been considered unlucky, being heavily timbered and lacking permanent water; James deepened the watercourses, stored water in huge 'tanks,' enlarged the estate from 3000 to nearly 50,000 acres, and established on it famous flocks of sheep and herds of cattle. Table Top wool in many years topped the Sydney market; the Table Top herd of Devons was in its time the largest in Australia. When rabbits became a pest, James wire-netted all his paddocks, and at the cost of £30,000 exterminated them from his run. He was also a renowned horse-breeder; but in this respect Thomas's family excelled him, Trafalgar and Patrobas (see RACING) having been bred at Bringembrong. From politics James, like the rest of his family, held himself strictly aloof, though he entertained at Table Top most of the leading Australians of his time, including the politicians. He died on 5 April 1914.

Thomas Mitchell of Bringembrong—he owned several other stations on the upper Murray—was a great trafficker in land; more than a dozen stations at one time or another passed through his hands. His younger son Peter Mitchell (the breeder of Patrobas), who died in 1924, bequeathed about £250,000 'to encourage and help the capable, healthy and strong to develop and bring to fruition their natural advantages.' Unmarried women under 30, youths under 21, the New South Wales police force, and the naval and military forces of the Commonwealth and the Empire, were designated as the special classes to be favoured. All candidates for prizes under the scheme are judged primarily by their physical and mental soundness, self-reliance, and initiative; for women, knowledge of the history and literature of the Commonwealth and the Empire is an additional qualification; for youths, success in sports and capacity for leadership. When the scheme of prizes is finalized, competitions will be held annually.

Mitchell, SIR THOMAS LIVINGSTONE (1792-1855), eldest son of John Mitchell of the Carron iron-works, was born at Craigend in Stirlingshire, Scotland, on 16 June 1792 and in 1808, after a little schooling, joined the army in the Peninsula as a volunteer, with the Duke of Wellington as his patron. He saw service at Ciudad Rodrigo, Badajoz, Salamanca, Vitoria, the Pyrenees, and San Sebastian, and on 14 June 1811 was commissioned ensign in the 95th Rifles (lieutenant, 1811; captain, 1822; major, 1826). As a volunteer the greater part of his time was spent in map-making and sketching, and so impressed was the war office by his work that in 1814 he was commissioned to prepare plans of the battle-fields and the positions of the contending armies. For a long time his models and plans were used at Sandhurst; they are now in the quartermaster's department and the United Service Institution. His work in this branch of military engineering secured him in 1827 an appointment in New South Wales. On 13 January 1827 (to quote from his diary) he was offered '3 difft. situations at New South Wales worth £500 a year each—a Collector, Civil Engineer and a second, or assistt., to Mr. Oxley, with the reversion of his appt.' He chose the last, reached the colony on 23 September, and immediately began his duties as deputy surveyor-general, occupying his time principally with map-making, road-surveying, and the collation of the numerous detached surveys to form a general map of the colony.

Oxley died on 25 May 1828 and Mitchell became surveyor-general; as such he not only accomplished the survey of eastern Australia and the division of its settled area into counties, but laid out towns, roads, and public reserves, and made personal surveys of the main southern (1829) and western (1830) roads with a view to their improvement. The main southern

road was then little more than a track made by the pioneers and the western road was still 'that wonderful, though somewhat primitive, highway which Captain William Cox had so expeditiously constructed to the order of Governor Macquarie in 1814.'

The explorations of 1831, 1835, 1836, and 1845, by which he is best known, are described under EXPLORATION BY LAND; they added vast territories to the colony, and resulted in the acquisition of a mass of extremely useful information concerning the geology, meteorology, and plant-distribution of the inland areas. These journeys were, however, merely episodes in the exacting and constantly increasing work of the surveyor-generalship. In 1829 the survey, construction, and maintenance of roads and bridges throughout the colony were put under Mitchell's control, and the steady expansion of settlement due to assisted immigration made it imperative to devote great attention to internal communications. When after 1836 Mitchell began to busy himself also with preparing for publication the journals of his expeditions, he found the strain almost too great. In 1838 he obtained leave of absence and went to England to see *Three Expeditions into the Interior of Eastern Australia* through the press. Queen Victoria knighted him, Oxford made him a D.C.L., and the war office, remembering the value of his survey-work in the Peninsula, belatedly promoted him lieutenant-colonel. Returning to New South Wales he wiped off arrears of office work and then by way of a hobby contested the election of representatives for Port Phillip in the new legislative council. In 1843 he was defeated, but in April 1844 was elected; in August, however, having discovered that as an official he was expected to support government measures unreservedly (though he had been elected as an independent member), he resigned, and turned his attention to preparing for the explorations of 1845. In that year he published in London the *Journal of an Expedition into the Interior of Tropical Australia*. In 1851 he was commissioned to report on the western goldfields of New South Wales. In 1853 he revisited England, taking with him a propeller for steamships which he had devised on the principle of the boomerang—this he patented in England and America, and it was tested successfully on the Queen's yacht and on H.M.S. *Conflict*. The Pioneers' Club, Sydney, has a model of this propeller. The last few years of his life were clouded with worry; bronchitis (brought on by exposure when laying out the Clyde bridge at Braidwood) set in, and he died at Darling Point, Sydney, on 9 October 1855. (Kt. Bach., 1838.)

The variety of Mitchell's literary work is startling. He began with two drill-books, a *Manual* and *Platoon Exercises*; in 1827 he published *Outlines of a System of Surveying for Geographical and Military Purposes*. Next came the two *Journals* already mentioned. In 1849 he issued *Notes on the Cultivation of the Vine and Olive*, in 1851 an *Australian Geography*, and in 1854 *The Lusiad of Luis de Camoens, closely translated*. In 1856 appeared a posthumous *Report upon the Progress made in Roads and Public Works in New South Wales*, dealing with the period 1827-55. His interest in art was shown when in 1842-3 Surveyor Davidson reported to him the discovery of 'masses of the most beautiful white marble' in the valley of the Abercrombie west of the main range. Mitchell at once asked for blocks of it for sculpture, and in August 1843 employed Charles Abrahams to model a bust to be cut out of one block—the first genuinely Australian sculpture. This (the subject is not known) was placed on a pedestal of the same marble 15 inches by 16 by 12, and for some years adorned Mitchell's house at Potts' Point; its fate is uncertain, but the evidence goes to show that it was broken up by some vandals for road-mending.

Mitchell's character was full of incompatibilities. He was a mathematician with high artistic attainments, a stern soldier with 'an excessive tenderness' for his fellow-beings and a strong sense of humour. He belittled the work of Sturt, but could praise the faithfulness, courage, and endurance of the convicts who served on his expeditions.

Mitchell, SIR WILLIAM HENRY FANCOURT (1811-1884), born at Leicester in England in 1811, migrated to Tasmania while still a youth and in April 1833 obtained employment in the colonial secretary's office in Hobart, rising to be assistant colonial secretary in 1839. The attraction of the newly opened Port Phillip district then drew him to the mainland, where he took up squatting in the Kyneton district. When the Victorian police force was disorganized by the turmoil of the first gold-rushes, Latrobe made Mitchell its chief commissioner, and his stern discipline, coupled with his far-sighted action in enlisting young enthusiasts as police cadets on probation, both re-established confidence in the force and practically suppressed a very dangerous outbreak of bushranging. After a visit to England in 1855 he was elected to the new legislative council of 1856 as a member for the north-western province of Victoria, and represented the first Haines ministry in the council until March 1857, though he held no departmental office; in the second Haines ministry (1857-8) he was postmaster-general, and devoted to the post-office the same talent that had remade the police force four years earlier. As a result he was in 1858 defeated at the polls, but was re-elected in 1860, and in December 1861 joined Haines in taking office under their former opponent John O'Shanassy. When this ministry left office in June 1863, Mitchell abandoned active party politics and busied himself with maintaining and strengthening the position of the legislative council. During the bitter attacks made on that body for its rejection of the tariff (1865) and the Darling grant (1867) because they had been 'tacked' to appropriation bills—see DARLING, SIR C. H., and MCCULLOCH, SIR JAMES—he stoutly maintained the council's rights, and in 1868 circumspectly aided the passage of a bill that re-established its influence by nearly doubling its electorate. His rewards were the chairmanship of committees in March 1869 and the presidency in October 1870. This office he held until his death on 24 November 1884. Apart from his political and squatting activities he was chiefly conspicuous as the mainstay of Goldsbrough and Company, one of the most important of Australian wool-selling firms. (Kt.Bach., 1875.)

Mites. See ACARINA.

Mocking-birds. Although this term is generally used to denote birds of the American genus *Mimus*, it may reasonably be extended to include many Australian birds which also practise voice-mimicry—a subject which has not been closely studied in Australia or elsewhere. Many problems still await solution—Why do birds use vocal mimicry? Does it serve any useful purpose? Has food or habitat anything to do with

the practice? Is it confined to particular orders or groups? Is mimicry taught by the parent-birds?

Australia's mocking-birds range from the lyre-bird, which is almost as large as a turkey in body, to the mistletoe-bird, which measures scarcely four inches over all. The lyre-bird is generally regarded as the finest mocker in the world; its voice is remarkably rich and flexible, and can render almost any sound from the puffing of a motor-omnibus to the squealing of young foxes. In semi-confinement the lyre-bird has been proved capable of voicing words; one attached to a farm in Victoria imitated to perfection a child crying, a dog howling, kookaburras 'laughing,' and drays moving, and also learned to say 'Gee up, Bess' and other words used by teamsters. The belief that mockery was confined to the male lyre-bird has been dissipated. The female also is an imitative vocalist. One in particular was heard and seen while she carolled like a magpie, laughed like a kookaburra, barked like a fox-terrier, yelped like a fox, and cackled like a hen. Sounds which the lyre-bird alone mimics, and which even it appears to find some difficulty in mastering, are the extraordinary 'laughter' of the kookaburra and the queer wail of the cat-bird.

This cat-like cry is one of the chief calls of another splendid mimic, the spotted bower-bird (see BOWER-BIRDS). It uses this call so freely and in such remote places that it may be a natural one—an original note which has been more firmly retained by its relative the cat-bird. Mockery of the cat-bird it is not—for, whereas the spotted bower-bird is a dweller in the great interior, the cat-bird is confined to the coast. In its general mimicry the spotted bower-bird shows a predilection for harsh sounds. Its voice lacks the flexibility of the lyre-bird's; the cries of hawks, butcher-birds, and frogs, and the creaking of branches it imitates to perfection, and it has even been known to imitate the twanging made by sheep when clambering through wire-fences, and the pattering of rabbits in a warren. The satin bower-bird, which frequents the scrub and jungle of the eastern coast, is also a mocker of marked ability, but is less consistent than some of its relatives. It has been known to mock the grunting of the koala (native bear) as well as the notes of other birds. Mockery is also practised by other species of bower-birds—except, apparently, the regent-bird, which appears to be a degenerate bower-bird.

The Tooth-billed Cat-bird (*Scenopoeëtes dentirostris*) of northern Queensland, long regarded as a bower-bird, is certainly allied to that genus in its fondness for mimicry and play, but in other respects approaches the cat-birds proper (*Ailuroedus*). The most startling imitations yet attributed to a toothbill were those of the whirring rattle of a just-caught cicada, and the distressed cry of a captive frog.

Other mockers are the scrub-bird (*Atrichornis*), yellow-throated and white-browed scrub-wrens, chestnut ground-wren, red-throat, silver-eye, oriole, drongo, bush-lark, gray butcher-bird, one or two thornbills (tits), one or two wood-swallows and the introduced starling. Most mockers spend most, or much, of their time on the ground, and so are more sensitive to sounds than those which maintain guard by means of vision; they have, too, more surplus energy than birds which are freely on the wing. These two considerations seem to touch the entire problem as to why birds mimic. They do but mock because they must—because of their high vitality, their sensitiveness to, and appreciation of, compelling sounds: in brief, because of their *joie de vivre*. As leisure or scope for mimicry increases, so does a bird's power of picking up sounds—always provided, of course, that physical ability is innate. This point may be appreciated by considering cockatoos, parrots, and certain other cage-birds, which in a state of nature are not imitative but readily acquire new vocabularies when given the leisure afforded by captivity. Dr. Walter Garstang has laid it down that birds are sound-lovers, who 'cultivate the pursuit of sound-combinations as an art, as truly as we have cultivated our arts of a similar aesthetic character.' This applies with special force to mocking-birds. It would appear, however, that limitations are largely fortuitous and purposeless. Many inland residents believe that the spotted bower-bird frequently uses mockery to draw intruders away from its nest; it is more probable that the bird is merely expressing anxiety in the only possible manner, borrowed notes having become part of its vocabulary—perhaps almost its entire vocabulary of major sounds. The emotions of courtship may stimulate mockery, but in many cases it is used by both sexes, and is frequently heard outside the breeding-season; the fact that it is more noticeable in the spring is merely an indication of the bird's increased vitality at that time.

The question whether imitative notes are inherited is a difficult one to answer. It is possible, but not probable, that the young of master-mockers, besides inheriting the ability to mimic, are gifted with actual borrowed notes—that is, such notes have become part of the vocabulary of the parents, and are, or may be, the baby's birthright. A lyre-bird has been known to imitate a circular saw some 30 years after the timber-mill in its area had been dismantled. Other lyre-birds have been known to reproduce the calls of birds which left their district about 15 years previously. It does not follow, however, that they inherited the notes; they may have been long-lived birds. The one cited earlier, which used the words 'Gee up, Bess,' was known to have been about the farm for 20 years.

The question whether birds teach their young to mimic is also an open one. Many bushmen hold that spotted bower-birds do so, not merely by casual force of example, but deliberately. It is certain, of course, that the song or call of its kind is born with every bird; but it is probable that tuition is required for the young of species whose songs or calls are complicated. A blue wren kept in captivity could only articulate half a bar at the end of 18 months. Definite tuition is not given by all parent-birds, however, for in most cases the offspring leave their parents before they have acquired a thorough grounding in music or 'elocution.' Probably this fact in itself plays a part in the development of mockery; and assuredly both mockery and improvization are prominent factors in the evolution of bird-song. A.H.C.

Mock Orange. See CAPPARIS.

Moffat, JOHN (1841-1918), born at Newmilns on the Irvine in Ayrshire on 26 May 1841, was in boyhood apprenticed to an ironmonger in Glasgow. Threatened with pulmonary trouble, he migrated in 1862 to Queensland, and obtained work on a Darling Downs station as storekeeper

and ration-carrier. Returning to Brisbane, he worked for an ironmonger there, then set up a store of his own in South Brisbane, and about 1869 moved to Stanthorpe on the border of Queensland and New South Wales, where he soon became interested in alluvial tin-mining. In 1880, hearing that payable tin had been discovered near Herberton in northern Queensland, on the tableland behind Cairns, he moved to that field, imported tin-dressing machinery, encouraged and took part in the opening up of tin, copper, and silver mines farther west, established headquarters at Irvinebank, and became known as 'the father of tin-mining in the north.' The Chillagoe mines and railway, and the Mount Elliott mines near Cloncurry, owed a great deal to his support, and he readily backed any prospector in search of tin, lead, silver, copper, bismuth, molybdenite, or wolfram. For some years a large proportion of the world's supply of wolfram passed through his hands. His active life from 1880 onwards was spent in the region he had opened up, where (besides the Herberton and Chillagoe enterprises already mentioned) he organized the exploitation of silver-lead at Muldiva (1890); copper at Mount Garnet and Mount Molloy (1898-1902); tin at Irvinebank (1883) and Coolgarra (1898); wolfram at Mount Carbine and Wolfram Camp (1899-1902); and coal at Mount Mulligan (1910). He also constructed lines joining Irvinebank and Mount Molloy with the main railway-lines. In 1912 he retired from the direct management of his northern properties and settled in Sydney. He died at Toowoomba on 28 June 1918, while on a business visit to Queensland.

Mole, Marsupial, a remarkably modified polyprotodont marsupial belonging to the family Notoryctidae. There are two species. One (*Notoryctes typhlops*) is confined to sandhills in central Australia, its discovery being made known to science as recently as 1888 by the late Sir E. C. Stirling (q.v.). It is a small animal, the head and body together being about five or six inches long, and the tail about an inch. The body is flattened from above downwards, and there is no neck; the snout is protected by a horny shield; the fore- and hind-limbs are nearly equal, very short and strong, and specially modified to act as burrowing-organs, the claws of the third and fourth digits of the fore-limb being enormously developed. The fur, which varies in colour from silvery to chestnut-brown, is long, soft, and silky. The tail is reduced to a rudiment and the skin is hard, rough, and marked with rings. The eyes are incompletely developed and buried beneath the skin, so that the animal is completely blind; the external ear is absent; the pouch opens backwards.

A second species (*N. caurinus*) was found at Wollal, near the Ninety-mile beach in north-western Australia, and described in 1920 by Oldfield Thomas of the British Museum. The general colour above was approximately 'pinkish cinnamon,' paler below. The claws and nasal pad are smaller than in *typhlops*, but the main distinction is shown in the skull, with its shorter muzzle and reduced dentition.

The food of the marsupial mole consists of ants and insects, in search of which it digs its way through the sand immediately beneath the surface, emerging at intervals to breathe. The burrows made in search of food are not permanent like the tunnels left by the European mole, though it is probable that deep permanent burrows are constructed in which the female lives when rearing her young. In captivity Professor Wood Jones has observed a handful of earthworms being noisily accounted for, while a specimen held in the hand partook of a quantity of milk. See MARSUPIALS. W.A.H.

Mole Crab. See HERMIT CRABS.

Molesworth, SIR ROBERT (1816-1890), born at Dublin on 3 November 1816, and educated at Trinity College, Dublin (B.A., 1826; M.A., 1833), was called to the Irish bar in 1828 and joined the Munster circuit. In 1852 he migrated to South Australia, but came to Melbourne in 1853, was admitted to the Victorian bar, and during the absence of Sir William à Beckett (q.v.) acted as chief justice. In November 1855 he became solicitor-general in the Haines ministry, in June 1856 was placed on the supreme court bench, and under a new statute became primary judge in equity. He frequently sat in the common law and criminal courts, and was the first judge of the court of mines. From August 1885 to May 1886 he acted as chief justice during the absence of Sir William Stawell. He retired on a pension in 1886, and died on 18 October 1890. J.V.C.-B.

Molle, GEORGE, joined the army in 1793 as an ensign (lieutenant, 1794; captain, 1795; major, 1803; lieutenant-colonel, 1808; colonel, 1814), served at Gibraltar and the Cape of Good Hope, and acted as aide-de-camp to Sir David Baird in India and Egypt. In 1803 he was sent to England with despatches, saw active service during the continental wars, and on 3 June 1813 was appointed lieutenant-colonel of the 46th foot, then under orders for New South Wales. On 20 June he was also commissioned lieutenant-governor of the colony. Reaching Sydney on 11 February 1814, he was welcomed by Governor Macquarie (an old comrade-in-arms under Baird), and on 28 March took the oaths of office. But the friendly relations between Macquarie and Molle did not last long. Before reaching the colony the officers of the 46th regiment had decided, with the tacit consent of their chief, not to invite to their mess any person who had been a convict; they had to meet emancipists at the governor's table, but would not otherwise associate with them. Macquarie was annoyed, but admitted their right to choose their own companions, and there was no open breach until 1815, when some of Molle's officers began to exercise their wit on the governor and his friends. In 1816 they applauded a caricature of him, and declined invitations to government house. About the same time a scurrilous lampoon on Molle was circulated through the town (see 'PIPES'); Molle, extremely angry, could not discover the author until D'Arcy Wentworth (q.v.) admitted that it had been written by his son William Charles—who by that time was on his way to England. The officers of the regiment, thus freed from suspicion, presented Molle with a congratulatory address, which in Macquarie's opinion embodied an attack on his administration; this put an end to any non-official intercourse between Macquarie and Molle, and Macquarie drew up a list of charges against the officers collectively for presentation to the commander-in-chief. Meanwhile Molle summoned D'Arcy Wentworth before a court martial, on the ground that he had aided and abetted the circulation of his son's lampoon; Macquarie, though considering the charges

of 'a most frivolous and ridiculous Nature,' ordered the court to be assembled, but his legal adviser the judge-advocate considered that a colonial medical officer was not subject to court martial, and the proceedings fell through. On 23 September 1817 Molle left Sydney with his regiment for Madras, where he died on 9 September 1823.

Mollusca. The *mollusca nux* of the Romans was a soft-kernelled nut with a thin shell. The transference of the name to shellfish was easy: and, though for scientific reasons cuttle-fish, slugs, and a few other animals not enclosed in shells are classified among molluscs, yet the vast majority of the species, whether they inhabit sea or land or running streams of fresh water, are protected by a calcareous shell. Among the higher invertebrata the division Mollusca is marked by a lack of such segmentation as occurs in insects, crustacea, and the higher 'worms' and of such radial symmetry as distinguishes the Echinodermata. About 50,000 living species of molluscs have been recorded, but less than 5000 have been recognized from Australia. A complete census, however, would add materially to the world-population, and proportionately more to the Australian. Some molluscs are viviparous; in some, e.g. cuttle-fish, several larval stages are rehearsed in the egg; but the normal mollusc lays eggs from which are hatched larvae destined to undergo complicated transformations. The earlier of these repeat the history of such forms as the chaetopod worms; the larvae, for instance, swim by means of quivering bristles set round the head. When this phase is prolonged, the infant mollusc may take advantage of winds and currents to perform long journeys. This is the secret of the wide dispersal of the oyster and other sedentary forms.

Mollusca have nerve-centres concentrated in the head, forming a sort of invertebrate brain. They can feel, see, and hear more or less acutely. Their blood is oxygenated by a gill or lung (or even by the cuticle), filtered by a kidney, and pulsated by a heart; but the ultimate ramifications of the circulation are indefinite. Their sex may be either monoecious or dioecious. The molluscan foot, perhaps developed from the ventral sucker of a worm, has been elaborated into a variety of shapes and uses, from the creeping sole of the snail to the fin of the heteropod, the tentacle of the squid, the spade of the pipi, and the auger of the cobra. The shell, which has passed through complicated phases of evolution and degeneration, is often provided with a lid (operculum) that closes the opening like a door. Another characteristic molluscan feature is the radula, which has a general resemblance, both in position and in function, to the tongue of a vertebrate. It is a hard, transparent, chitinous structure consisting of minute plates arranged like a pavement, each bearing a backwardly directed hook or prong. With this instrument a carnivorous gasteropod can drill a hole through the shell of its victim, and tear out the flesh afterwards. The pattern of the radula-teeth is varied, and is a useful criterion in classification.

To savage races molluscs are of far more importance than they are for any civilized people. Probably no mollusc of sufficient size has ever been neglected as food. From various shellfish the Australian aborigines derived subsistence, implements, and ornaments. Old native camps round Sydney are still marked by huge piles of bleached and broken shells of the larger species (such as *Cymatium*, *Turbo*, and *Haliotis*) intermingled with lesser kinds such as the limpets; even the chitons were not despised. A cockle (*Arca trapezia*), occurring in sheltered bays, yielded so plentiful a food-supply that MacGillivray described the stacks of discarded valves at Brisbane Water as extending for 100 yards in length and 20 feet in height. Various species of a mussel (*Diplodon*) from freshwater pools were esteemed either raw or roasted. A valve of some large stout bivalve was generally carried in a basket to serve as a knife. Fish-hooks were rasped out of various

Turbo stamineus.

shells. In the tropics the melon-shell was used as a canoe-bailer, the *Megalatractus* as a bucket, the *Charonia* as a trumpet, and the giant clam as a tank. From pearly nautilus, which are stranded all along the Pacific beaches, the coastal tribes used to cut the septa, fashion them into ornaments, and trade them to inland tribes. Pearl shells were carved into crescents and slung across the chest by natives of northern Queensland. The Tasmanian aborigines used to decorticate and string together the iridescent *Cantharidus*, which is now sold in Hobart to tourists.

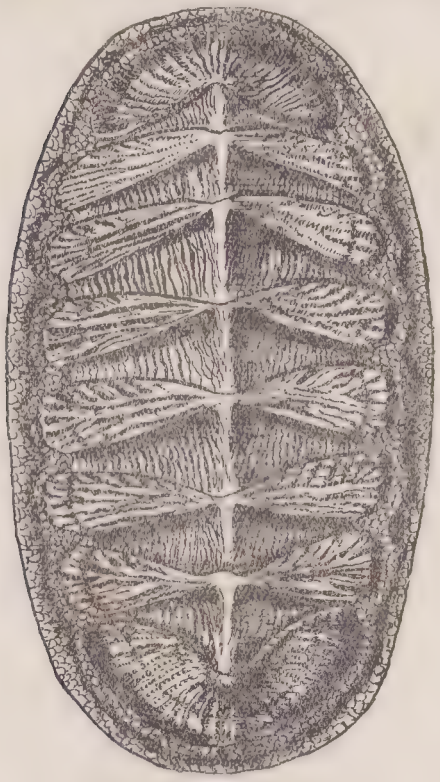
The Amphineura, the lowest grade of mollusc, more nearly represent the ancestral form, being straight and bi-laterally symmetrical. On the back are eight overlapping shelly plates set in a band of muscle, which resemble the plates of armour worn by medieval warriors and suggested the name of chiton (mail-clad) for the tribe. The muscular periphery, which is usually scaled on the outside—the scales appearing in *Sypharochiton* like a tessellated pavement, and in *Acanthopleura* like a forest of spines—enables the chiton to cling firmly to rocks.

The chiton fauna of Australia is unusually rich, amounting to about 130 species; they occur along the whole coast, but are most abundant in the colder southern waters; each species is usually restricted to a particular zone on the beach. Many interesting and peculiar forms are included in this fauna. *Schizochiton*, a tropical form, has developed an elaborate series of dorsal eyes, which like sparkling beads stud the surface of the valves. The genus *Cryptoplax* has progressed furthest in the reduction of the plates, thus acquiring a suppleness by which it is able to worm itself into the smallest crevice. The species of *Stenochiton* seek an unusual refuge in the axils of the ribbon-like leaves of the sea-grasses *Zostera* and *Posidonia*.

The Cephalopoda (octopi and squids) are accounted the most elaborately organized of all

1. *Oliva sericea* (Barrier Reef).
2. *Spondylus wrightianus* (Western Australia).
3. *Janthina violacea* (Sydney).
4. *Trigonia lamarckii* (Sydney).
5. *Lambis scorpius* (Barrier Reef).
6. *Mitra mitra* (Barrier Reef).
7. *Scaphella bednalli* (Northern Territory).
8. *Strombus luhuanus* (Barrier Reef).
9. *Turbo petholatus* (Torres Strait).

mollusca; they are also the most active, the largest and the oldest survivors of the sub-kingdom. Their body usually takes the shape of a sack. In the lower part of the bag are the viscera; on the constricted neck are two large,



Ischnochiton australis.

highly developed eyes, together with a slit and funnel for inspiration and expiration. The entrance of the sack is slashed to form eight or ten long arm-tentacles, beset with rows of suckers. In the centre of the disk formed by these tentacles is a mouth, armed with a pair of jaws like the beak of a parrot. Most cephalopods have an internal shell and a bag of ink. An old-world name for the squid was 'sea-clerk,' because, the fishermen said, he always carried with him his pen and ink. This ink is the sepia of commerce. In time of danger the squid squirts from the funnel a cloud of sepia ink in which it vanishes from the sight of an enemy. There is nothing in the sea more mobile than a cephalopod, for it can crawl away on its arm-feet, swim with its arms and fins, and dart backwards by driving water from the respiratory funnel. Most cephalopods can change colour like a chameleon, and so conceal themselves by taking on the colour of the background, whether rock or sand. In the North Atlantic are giant squids, exceeding 40 feet in length, but only species of moderate dimensions occur in Australian waters.

The white, brittle, and graceful shell of the paper nautilus (argonaut) is a nest rather than a house; fleets of these shells are sometimes stranded on Australian beaches. The pearly nautilus, whose nacreous whorls are partitioned into many chambers, lives on the Barrier Reef. During aeons of geological time this animal has changed less than almost anything in the world. The little post-horn shell of *Spirula* is commonly stranded on every beach of this continent; the animal, which is considered a rare prize by zoologists, probably lives in deep water off shore. The Australian octopus, squid, and cuttle-fish are much the same as in other parts of the world, and are chiefly valued as bait for fishermen.

The bivalve Pelecypoda include the cockle, the oyster, and the mussel. Their soft body is boxed up in a hard, scarcely penetrable pair of shells hinged together, which may be thrown open by a spring and shut by the contraction of bands of muscle. This safe refuge is purchased at the cost of a comparatively inactive life, and has consequently entailed considerable atrophy and degeneration. Oysters and the oyster industry are discussed separately. Among mussels *Mytilus planulatus* is excellent eating, but is not generally known or appreciated. A fine scallop, *Pecten meridionalis*, occurs in Tasmania, but the fishery is restricted. The Pipi (*Donax deltoides*) is a smooth, wedge-shaped, purple bivalve about two inches long, abundant in temperate waters on ocean beaches, where it may be found sunk in the sand in the wash of the surf. The aborigines consumed it largely; modern fishermen use it for bait. 'Pipi,' the name in use in New South Wales, has been adopted from the Maori; in southern Queensland it is known by an aboriginal name, 'ugarie.'

'Bone' or pen of *Sepia mestus*.

Pearl oysters (for which see PEARLS AND PEARLING) are the most important of Australian bivalves.

On the reefs of the Barrier occurs that largest of bivalves, either recent or extinct, the Giant

Clam (*Tridacna gigas*). The heaviest known pair of shells of this species are the famous holy water basins of the cathedral of St. Sulpice in Paris, which together weigh 550 lb.; the maximum size recorded is a length of four feet six inches and a breadth of two feet five inches. The huge shells lie loose on the surface of the

Tridacna elongata.

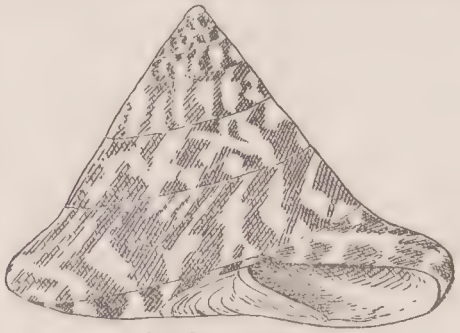
coral-reefs, with the hinge underneath, and when they gape a brightly-coloured mantle is displayed. Captain Cook used these giant cockles as fresh meat for his crew, finding a single one more than a hungry sailor could eat at a meal. A later explorer in Torres Straits, Matthew Flinders, says that on a waterless islet native sailors had improvised tanks by laying out *Tridacna* valves to catch the rain-water. On coral islands, where hard stone was unprocurable, the Polynesians often fashioned axe-heads from *Tridacna* shell.

Trigonia shells are beautifully pearly within, and externally are ribbed with rows of beads; jewellers make brooches and spoons of them. From a geological point of view this genus is of extreme interest because, while all living species are confined to Australian waters, a hundred other species flourished in European seas during the Jurassic and Cretaceous epochs. *Trigonia* is more abundant and of a larger size in Tasmania than elsewhere, but in one form or another is represented everywhere on the Australian coast. Nine species of shell are figured on plate xxvii.

All these bivalves are serviceable to mankind. One, however, is a pest to civilized humanity. In every sea shipworms (*Teredo*) are represented; those that occur in Australian waters have received locally the name 'cobra,' and one that bores a hole an inch in diameter is among the largest in the world. No vegetable substance, hard or soft, seems to be immune from cobra, whose depredations reach from the surface to any depth. The piles of wharves, bridges, or beacons, the hulls of ships, boats, or punts, any submerged timber, floating or fixed, may be quickly riddled by this pernicious mollusc; in the tropics its activities may even extend into fresh water. The attack is commenced by a larva of invisible size, attracted to the timber by a sense analogous to that of smell. A pin-hole in a sheath of metal is ample entrance for the minute visitor which, settling on the wood, rapidly develops adult features. The burrow is excavated not for food but for shelter, as is shown by the wall of shell that lines the tunnel, sometimes to its end. To suit the special circumstances of its existence, the cobra assumes an elongated-worm shape. At its upper and narrower end are two slender tubes (siphons) which reach outside the burrow and obtain both water for respiration and food in the form of floating animalculae. At the lower and thicker end the shipworm has a ring of shell (modified valves), and projecting through the valves is a tough knob, the foot. When boring, the walls of the burrow are gripped by the expanded valves, whose surface is roughened for this purpose, and from the fulcrum thus obtained the foot rasps at the end of the burrow. This action can be heard by putting the ear to an infested pile or plank. The cobra which has entered a boat may be destroyed by drawing the boat out of water and allowing it to dry. An infested pile may be cured by enclosing it in a larger cylinder of metal or canvas, and filling up the intervening space with sand, thus choking the cobra. The usual methods of protection are to give the wood an impenetrable coat either by charring with fire or by sheathing with copper or tar; but logs so coated are safe only as long as there is not the slightest hole to admit the floating larva.

The Gasteropoda (snails, limpets, etc.) compose the most numerous, varied, and characteristic order of molluscs. This group has spread from seas to rivers, and thence to the land. Some species have degenerated into parasites on Echinodermata, others harbour parasites hurtful to man. Usually the body is ensconced in a convoluted shell, but this may be reduced to a cup or plate, or be altogether lost. Originally this shell was an elongated cone like a worm-tube, closed with a movable door (operculum). To render it more compact and convenient for transport, the originally straight shell was rolled up into a spiral; then the coils set up such a strain that organs on the compressed side of the body were atrophied. The paired gills and other organs, which had been symmetrical in the primitive mollusc, were thus reduced to odd, lop-sided expressions. The operculum, which once probably grew turn for turn with the original spiral, ceased to revolve, developed various eccentric forms, and frequently disappeared.

Not many gasteropods are of economic interest. Of late years the demand by button manufacturers for mother-of-pearl has greatly increased, and as former sources became exhausted, fresh material has been eagerly sought. *Trochus niloti-*



Trochus niloticus.

cus (called in the trade 'trocas' shell) came into use. It is a top-shaped shell, about three inches high, coloured with broad stripes of alternate red and white, beneath which is solid mother-of-pearl. It was formerly abundant on the coral-reefs of northern Australia, but through vigorous collecting has become comparatively scarce. The shells are gathered by hand, cleaned of the fish by boiling or rotting, and then bagged up for the Japanese market. The animal is sometimes smoked and exported also. In the factories the shell is by machinery cleaned of its coloured

exterior and cut into disks. These, when smoothed, perforated, and carded, are pearl buttons finished for the market. Abroad it is illegal to take *Trochus* under a diameter of eight centimetres, but no such restrictions are placed upon the industry in Australia.

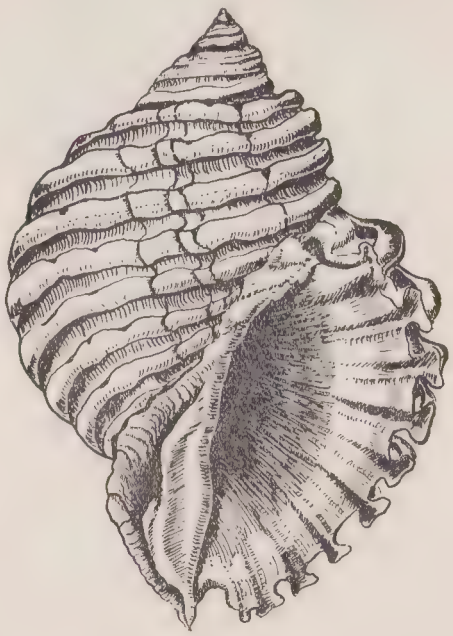
Seldom are gasteropods injurious, but an Australian species is capable of inflicting severe injury, and even death. *Conus geographus*, a gaily-painted, cylindrical shell about three inches long, lurks under stones on coral-reefs, but is so uncommon that few Europeans see it alive. The salivary glands of this and the related species *C. textilis* and *C. tulipa* excrete a venom, the poisonous effects of which resemble those of curari, and the radula has developed long, sharp points by which *Conus* stabs its victim and administers a minute dose of poison. The stab is extremely painful, and quickly disables the sufferer; control of the muscular system is lost (though the heart and lungs remain unaffected), and the limbs are rapidly paralysed. The paralysis continues for several hours, and may end fatally. The native method of obtaining relief is to cut the flesh round the wound, inducing blood to flow.

Any one of the numerous species of *Bullinus*, a genus of freshwater snails commonly occurring in ponds throughout Australia, may be the intermediate host of the liver-fluke of sheep. *Bullinus* is also dreaded as a potential harbour for bilharziosis (see BLOOD-FLUKES).

Haliotis is a saucer- or spoon-shaped shell, lined inside with brightly iridescent pearl, and pierced by a row of holes parallel to the margin. It clings to rocks like a limpet. In Australia it is called 'mutton-fish,' in New Zealand 'pawa,' in California 'abalone,' and in England 'ormer' or 'ear-shell.' Species of *Haliotis* occur everywhere on the Australian coast; some southern

Haliotis naevosa.

forms may reach a diameter of five or six inches. In Tasmania the coastal blacks formerly relied on *Haliotis naevosa* as an important article of food. They dived for the shell, detached it from the rock with a wooden knife, and carried it away in reed-baskets. In 1869 a party of Chinese at Southport in Tasmania prepared *H. naevosa* for export by cutting the mutton-fish from the shell, drying it in a slow oven, and packing it in casks for the Chinese market. At Twofold Bay P. P. King found the aborigines using the shell for drinking-vessels. Characteristic of rocky, surf-swept headlands is the genus *Thais*, in which a large and solid shell is fortified by various devices. The Sydney species develops massive rings, which are so prominent that Chemnitz, an eighteenth-century conchologist, proposed, on account of the intervening furrows, to call it the 'cart-rut' shell. The Conch-shell (*Charonia tritonis*) is found on the northern coasts of Australia. Polynesians and Melanesians used it in peace or war to blow a loud warning signal. An even larger conch—the largest recent gasteropod shell, indeed, in the world—is *Megalatractus aruanus*, which reaches a length of two feet, and ranges from Fremantle to Torres Straits, and thence to Port Curtis. The aborigines ate the mollusc, and manufactured the shells into trumpets, nose-pins, and water-carriers. But to them the most useful of all molluscs was the Melon or Bailer-shell (*Cymbium flammeum*), which served for a canoe-bailer or cooking-pot, or for personal adornment; the animal was also eaten. The shell is large, smooth,



Thais succincta.

and oblong, a foot long, prettily marbled with orange, white, and brown, and with a crown of arched scales at the narrower end. Also common on coral-reefs is the Spider-shell (*Lambis lambis*). It is about eight inches long and very massive; the outer lip is produced into a series of claws, the inner is polished and rose-coloured. South Sea islanders carved the solid shell into various implements, and ate the animal.

Cowries have always been admired for their splendid polish and beautiful colour. Some have been disinterred from the graves of prehistoric people, who prized them as charms for fertility. The Money Cowrie (*Cypraea moneta*), which once passed as current coin in Africa, is plentiful in Queensland. A large white shell, inhabited by a black animal, is called the Poached-egg (*Ovulum ovum*). Many other species occur in Australian waters, including those most prized by amateurs. Limpets, as elsewhere, are scattered over the rocks between high and low tide levels, exposed to the utmost fury of the surf. The species commonest around Sydney is *Cellana variegata*. After an easterly gale the drift-line on any Pacific beach may be adorned with a long purple streak—thousands of wrecked, frail, purple *Janthina*; one species is about the size

of a pea, another resembles somewhat in size and shape the garden snail. Fast to the purple snail is bound a little raft of packed bubbles composed of mucus, which float the animal on the surface and on which the eggs are laid and hatched.

Cypraea lynx.

The Australian land-shell fauna is still incompletely known, new species remaining to be described probably from every State. Queensland, into which a fauna descended from New Guinea by way of Torres Straits, is richest both in number of species and beauty of specimens. To this region are confined the operculate snails (*Helicina, Pupina, Pupinella, Leptopoma,* etc.), which gradually dwindle away southwards till the last straggler, a *Helicina,* is reached at Port Macquarie. Large and handsomely-banded *Hadra* characterize the Queensland coast, occurring on the ground in the jungle or cedar-brushes; with them are species of *Hedleyella* of the size of an apple, coloured in shades of brown and chestnut. The trunks and leaves of the trees are inhabited by species of *Papuina.* Usually each of these ranges over a few degrees of latitude, and is then succeeded by a related form. The carnivorous snails are exemplified by *Rhytida,* with discoidal, glossy, chestnut-brown shells. Slugs, which are fewer than in other countries, are represented by the indigenous genera *Atopos, Aneitea,* and *Cystopelta.* Even the arid regions of central Australia have a few species of snail, which have become adapted to desert conditions.

The Tasmanian fauna, which has been more closely studied than the Australian, includes about 56 species, mostly small, flattened, and radially-sculptured shells belonging to the Endodontidae. There are, besides, a variety of carnivorous species, a single *Helicarion* and a *Chloritis.* The Macroogona are represented by two large and showy monotypic genera, *Caryodes* and *Anoglypta.* An arboreal *Bothryembrion* is a distant member of a great South American family, Bulimulidae. Further, a considerable number of European snails and slugs have established themselves in the settled districts throughout the Commonwealth. C.H.

Mollymawk. See ALBATROSSES.

Molucca Beans. See CAESALPINIA.

Molybdenum, a rare metal occurring in many parts of the world but usually in such small quantities as not to be available for commercial treatment. The world's supply is chiefly obtained from Quebec in Canada, Cumberland in England, Norway, and Australia.

In Australia it has so far only been mined in commercial quantities at Everton in Victoria, on the Chillagoe field in Queensland, and at Kingsgate, Deepwater, Bolivia, and other places in the New England district of New South Wales. The only ore of molybdenum is the sulphide (molybdenite); this, not the metal, is taken as the basis of market transactions, the price quoted being so much per unit of molybdenite—one unit is 22.4 lb., or one-hundredth of the number of pounds in one ton.

Formerly the uses of molybdenum were very limited, but since it has been discovered that its presence in steels increases their tensile strength, elasticity, and hardness, it has been in greater demand. Molybdenite has to be dressed up to at least 85 per cent, and must not contain more than 0.5 per cent of bismuth. To free it from other minerals, the ore has to be broken up. No one machine can do this satisfactorily, so the reduction takes place in stages, the class of machine employed for each stage depending on the size required. It is first reduced to about half an inch in one or more rock-breakers; from these it is passed on to rolls, where it is crushed so as to pass through a screen with ten holes to the linear inch; finally it is reduced so as to pass through a screen with 24 holes to the linear inch, the best machine for this being a ball-mill of the Krupp type. All this crushing is done in the dry state; the final product is passed over a shaking screen, and the oversize is returned to the ball-mill.

Molybdenite does not lend itself to concentration by gravity, because it breaks up into flakes and, in spite of its high specific gravity, easily floats away; but treatment on jigs and tables will help to get rid of certain associated minerals. At small isolated deposits, should the molybdenite occur in sufficiently large pieces, cobbing and hand-picking are resorted to. The most satisfactory method of treating molybdenite is by flotation, for which two methods are in vogue in Australia: (1) surface-tension, developed at the northern Queensland mines, (2) the mineral separation or frothing method. The former produces a higher-grade concentrate; the latter saves more molybdenite, but is not so clean, more impurities being carried over and the grade thus reduced.

The Irvinebank type of surface-tension consists in mixing the mineral pulp with oil (generally kerosene); this is fed by a shaking screen to a slightly inclined board, the lower edge of which dips under water at one side of an inverted pyramidal box. The molybdenite floats across the surface of the water to an overflow lip on the opposite side, and then passes to a settling-box, while the residue sinks to the bottom and is delivered through a spigot

to the shaking feeder of the next box. There are four such boxes to a system.

In the frothing process the dry, powdered material is passed into a trough-mixer, where it is stirred up with the necessary quantity of water and about ¾ lb. to one lb. of eucalyptus oil per ton of ore, and passed into the top end of a six-cell flotation machine. The details of the work vary with the nature of the ore. If the ore is low-grade, a larger quantity can be handled in a given time than if it be higher-grade. Further, low-grade froth from the last three cells may be returned to the first cell for re-treatment, whereas if the ore is high-grade it may be only necessary to return the froth from the last cell. Sometimes a little sulphuric acid and carbonate of magnesia (or lime) are added to assist the float. If bismuth sulphide is present in the ore, it is apt to rise in the boil of the last one or two cells, but the addition of more oil at this point prevents this action. The froth is run into settling-tanks, where it is allowed to remain for about eight hours (a little sulphuric acid being added to help the settling); the water on the top is then syphoned off. If the concentrate still contains over 0.5 per cent of bismuth, the ore has to undergo further treatment in a sub-aeration machine; this machine consists of a cylinder, the lower two-thirds of which is divided into compartments by ten sheet-iron baffle-plates, set at a tangent and extending from a central tube to the periphery: below this a stirrer, actuated by a spindle that passes through the central tubing, revolves at the rate of 840 revolutions per minute. Air passes into the bottom of the machine through a pipe, while water is admitted through the side from another pipe connected with the apparatus a little above the bottom. The concentrates may be added intermittently as a charge by hand, or continuously and automatically by machinery. When set in motion, the molybdenite rises to the upper part of the cylinder as a froth, and flows from the lip to a settling-tank; the water is drawn off, and the sediment dried over a furnace. The bismuth sinks to the bottom of the sub-aeration machine, and is drawn off through a hole at the bottom.

In 1925 from the quantity of molybdenite ore raised in the Commonwealth 870 cwt. of concentrates, valued at £7464, were produced. Over 70 per cent of this yield came from Everton near Beechworth in Victoria, about 15 per cent from the New England district of New South Wales, and the rest from the Chillagoe and Mount Perry districts of Queensland. Molybdenite also occurs at Moonta and Yelta in South Australia, at Yenberrie in the Northern Territory, and sporadically in Western Australia. See MINERALOGY.

F.D.P.

Monash, SIR JOHN, born at Melbourne on 27 June 1865 and educated at the Scotch College and the university of Melbourne (M.C.E., 1891; B.A., 1895; LL.B., 1895), in 1884 commenced practice as a civil engineer. In 1900 he introduced reinforced-concrete construction into Victoria, Tasmania, and South Australia; in 1913-15 he was president of the Victorian institute of engineers. From his university days he was an enthusiastic officer of the citizen forces, and his power of keen, lucid exposition was noticed by Sir Ian Hamilton and other inspecting officers who visited Australia. In 1887 he received his first commission (lieutenant, 1887; captain, 1895; major, 1897; lieutenant-colonel, 1908; colonel, 1913; brigadier-general, 1914; major-general, 1916; lieutenant-general, 1918), in 1901 he commanded the North Melbourne artillery, and from 1907 to 1914 was an officer of the intelligence corps; on the outbreak of war he was appointed chief censor for Australia. Within a month, however, he was given command of the 4th infantry brigade, which became part of the New Zealand and Australian division under Major-general Godley. He accompanied his brigade to Gallipoli, where during the landing operations it reinforced the battalions holding the centre and shortly afterwards became responsible for the defence of that sector at the head of Monash Valley. In the great offensive in August his brigade was given the task of reaching, by a night operation through the foothills, the summit of Hill 971, some four miles distant. In the morning, at a critical moment, Monash himself made his way to its head and directed it into the hills, but the effort failed. Shortly after the transfer of his brigade to France he was appointed to command the 3rd Australian division, which he trained in England and led to the western front, where it took part in the battle of Messines, the third battle of Ypres, and the operations which checked the direct German advance upon Amiens. His obvious capacity, especially in the higher commands, marked him to succeed General Sir William Birdwood in command of the Australian army corps in France when, in May 1918, Birdwood was transferred to the Fifth British army. In the elaborately planned action at Hamel on 4 July 1918 the new corps commander showed what could be done by the careful co-operation of infantry with tanks, aeroplanes, and artillery; and his methods thus tried were to a large extent subsequently adopted in the British offensive of 8 August. Partly in consequence of that ascendancy established by Australian troops over the enemy confronting them which was impressed by Monash upon General Rawlinson, commander of the Fourth army, the sector of the Australian Corps was chosen for the commencement of the Allied offensive of 8 August 1918. Monash's plans for the operation of his corps were entirely successful, and during the advance he at times commanded no fewer than eight divisions. When the advance reached the southward bend of the Somme at Péronne, his clever transfer of two divisions to the north bank resulted in the capture of Mont St. Quentin and the turning of the German position. By 6 October when the Australian divisions, after the piercing of the Hindenburg line, were withdrawn for rest, Monash had become recognized as one of the ablest corps commanders in the British army. After the armistice he was appointed director-general of demobilization for the A.I.F. (see AUSTRALIAN IMPERIAL FORCE). In 1920 he published *The Australian Victories in France in 1918*, which described the work of the army under his command and laid stress on the part played by engineering in modern warfare; this won him the degree of doctor of engineering, the first granted by any Australian university. In August 1920 the Victorian government appointed him chairman of the State's electricity supply commission (see YALLOURN). In 1924 he was president of the Australasian Association for the Advancement of Science. (C.B., 1915; K.C.B., 1918; G.C.M.G., 1919.)

C.E.W.B.

Monazite. See MINERALOGY.

Monimiaceae, a family of trees, shrubs, or woody climbers, largely represented in tropical

South America, with a few widely scattered extra-tropical species. *Hedycarya angustifolia* (Native Mulberry) a small tree with unisexual flowers on distinct plants, is an endemic species ranging from Victoria to Queensland. The aborigines of southern New South Wales used the wood of this tree for spear-heads, and for producing fire by friction. *Palmeria scandens*, a graceful vine found sparingly in New England (New South Wales), is rich in a pure tonic bitter, and for many years formed the basis of a minor local industry, being exported to the continent of Europe for use in the manufacture of beer. See DAPHNANDRA and SASSAFRAS.

Monkey Nut. See HICKSBEACHIA and PEANUTS.

Monk-fish. See ANGEL SHARK.

Monotoca, a genus of the family Epacridaceae, consisting of shrubs or small trees with more or less unisexual flowers crowded on short spikes, endemic in Australia. *M. elliptica*, the 'Port Jackson Beech' or 'Pigeon-berry' ('wallang-unda' of the aborigines), is a small tree with a silvery-grained timber. It must be planed across the grain, and was formerly used for planes and other carpenters' tools. *M. scoparia* has a pale-yellow wood, nicely marked and easily worked.

Monotremes. The term 'monotreme' (i.e. 'single opening'), first applied by Etienne Geoffroy Saint-Hilaire, refers to an anatomical feature which they share with birds, reptiles, and amphibians—the single aperture or 'vent,' which is the sole outlet of a chamber (cloaca) common to the intestinal canal and the urinary and reproductive systems. Another peculiarity in which these mammals resemble birds (as well as the other classes of lower vertebrates) is that in monotremes the two oviducts are separate throughout their entire extent, instead of undergoing various fusions as in all other mammals.

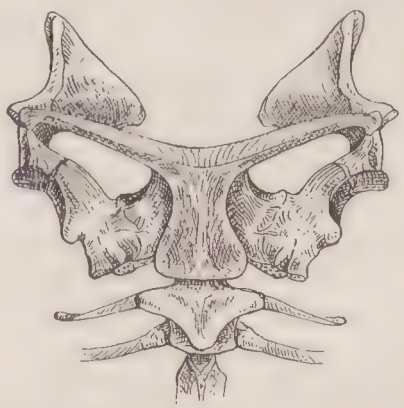
They belong to the lowest order of mammals, and differ from all other mammals in certain important features of their structure and development, in several of these approaching reptiles and birds. It is uncertain whether any of the known extinct mammals were monotremes, but the only surviving representatives of the order are the Platypus (*Ornithorhynchus anatinus*, also known as *O. paradoxus*), the Native Porcupine or Echidna (*Tachyglossus aculeatus*)—also called 'native hedgehog' and 'spiny anteater'—and the three-clawed and five-clawed *Zaglossus* (*Proechidna*) of Papua (see ECHIDNA and PLATYPUS).

Though the platypus and the echidna are so nearly related that they may be regarded as members of the same mammalian order, the superficial resemblance is not very close, and each is classed as a separate family. Both have a very short, thick trunk and short and powerful limbs, each provided with five digits armed with strong claws; both have the snout-and-jaw region developed into a kind of beak or rostrum; the males of both are provided with a large horny spur, curved and pointed, on the inner side of the hind-limb, connected with a special gland; both have small eyes, and are devoid of the conspicuous outer ear which forms so marked a feature in other mammals. But in other respects the differences between the two animals in appearance, as well as in structure and habits, are very strongly marked.

The platypus is distributed over southern Queensland, New South Wales, Victoria, South Australia, and Tasmania. The echidna (of which there are several varieties) is found all over continental Australia, Tasmania, and southern Papua. The platypus and echidna are described under their own names. Of the two species of *Zaglossus*, *Z. bruijni* occurs in western and *Z. bartoni* in eastern New Guinea. The distinctive character of *Zaglossus* is the great length of the narrow snout or beak, which is about twice as long as the rest of the head and is bent downwards. Six forms of *Z. bruijni* are known, all with three or four claws on each foot; of *Z. bartoni* two forms only occur, and all known specimens have five claws on each foot.

One of the points which render monotremes unique among mammals is that, instead of being viviparous (i.e. bringing forth their young in an advanced condition of development), they resemble the majority of the lower vertebrates in being oviparous (i.e. laying eggs which contain as yet only an imperfectly developed rudiment of the future animal, the further development of which takes place outside the body of the parent). The fact that monotremes lay eggs, repeatedly asserted and repeatedly denied, was authoritatively and conclusively established by W. H. Caldwell in 1883-4.

All monotremes possess the mammary glands, whose secretion serves to nourish the young in the early stages of their existence; but in certain special features, relating to their structure and the nature of their secretion, these glands differ widely from those of all other members of the class. Other distinctive features are to be found in certain parts of the skeleton. One is the presence of a T-shaped bone (episternum, or inter-clavicle) in the lower or ventral part of the skeleton of the trunk; the stem of the 'T' articulates with the sternum or true breastbone; the cross-piece is in close relation to the collar-bones of the fore-limb. Such a bone does not occur (save as an obscure vestige in certain examples) in other mammals, but is well-developed in most reptiles. Another characteristic feature



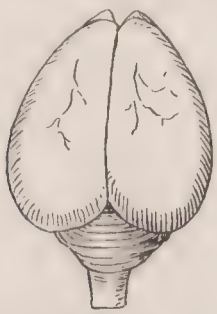
Coracoid bones of echidna (ventral view).

is the presence of complete coracoid bones. In the lower air-breathing vertebrates, the pectoral arch (that portion of the skeleton which supports the fore-limb) consists of three distinct elements —the scapula, coracoid, and clavicle—meeting at the shoulder-joint. In all the higher Mammalia the coracoid element is reduced to little more than a vestige, whereas in monotremes it is a well-developed bone (or rather two bones), joining the shoulder with the breastbone.

As in most marsupials, there are in monotremes epipubic or 'marsupial' bones connected with the

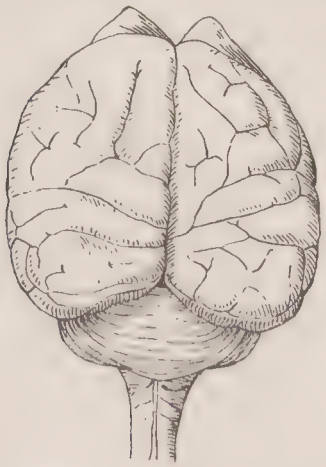
pelvis. The skull also is peculiar, one of the most striking points being that the constituent bones become fused early, the sutures (lines of articulation) being obliterated and the surface assuming a smooth, polished appearance. In this respect, as in the form of the beak, monotremes are superficially somewhat bird-like. Essentially, however, the resemblance is not a close one; the skull, while possessing certain reptilian features not shared with the higher mammals, is very definitely mammalian. The lower jaw, like that of other mammals—and unlike that of reptiles and birds—consists of a single bone on each side. It is greatly reduced as compared with that of other mammals, and the upright part is absent.

The monotreme brain falls short of the normal mammalian standard in certain respects, but not much more so than the marsupial brain. Though in this there is no essential difference between platypus and echidna—since both lack an im-



Brain of platypus (dorsal view, natural size).

portant brain-structure that is present in all other mammals except the marsupials—there is a great difference between the two in brain development: the cerebral hemispheres (the seat of the higher brain-activities) of *Tachyglossus* are larger and much more highly organized than those of *Ornithorhynchus*. This difference is doubtless to be associated with the wide difference in habits and mode of life; the compara-



Brain of echidna (dorsal view, natural size).

tively circumscribed environment of the platypus does not call for, or develop, the same amount of intelligence as that of its more freely roving relative.

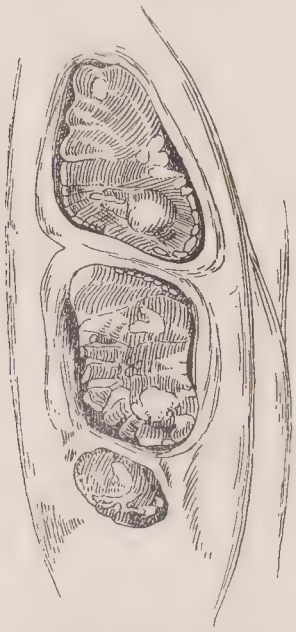
Another difference concerns the organs and nerve-apparatus connected with the olfactory sense. The echidna has the entire apparatus rather highly developed, whereas in the bill of the platypus it is much less elaborate. To compensate for this deficiency in the sense of smell, the platypus has about the beak a system of minute papillae, which seem to be organs concerned with a specially refined touch-sense. To quote Professor G. Elliot Smith (q.v.), to whom we are indebted for the most comprehensive investigation of the nervous-system of these lowly mammals:—

> It can easily be conceived that, as the animal spends much of its time in dark subterranean channels, where impressions of sight and hearing avail little, the sense of touch should be of most service, and, together with the sense of smell, should be a guide sufficient to the needs of this strange creature. . . . But when at dusk the animal leaves its burrow and takes to the water, the sense of smell is of little avail, and the creature may be seen swimming about the surface of some quiet pool, with its sensitive beak just below the surface of the water, responsive to every ripple that marks the surface. At such times vision and hearing can be but accessories to the more acute sense of touch.

Of some interest in connection with the relationship of monotremes to other animals is the observation, first made by Mikluho-Maklay (q.v.) in 1879, that the temperature of the blood in *Tachyglossus* is considerably lower than it is in other mammals. The temperature in the latter (including the marsupials) is comparatively high (36° C. and higher), and very constant; in reptiles it is scarcely above that of the surrounding air, and varies with it. In *Tachyglossus* the temperature averages about 30° C., and is more readily affected by changes in the temperature of the air than it is in other mammals. As pointed out by Wardlaw, however, this peculiarity is by no means so striking as has sometimes been supposed, especially when we compare *Tachyglossus* with mammals belonging to higher groups that pass through a period of hibernation, wherein the conditions as regards temperature approximate to those prevailing in reptiles. In *Ornithorhynchus* the temperature is more constant than in *Tachyglossus*.

While monotremes display features that must be regarded as primitive, additional interest in the problem of their position in the animal kingdom is derived from a recognition of the fact that they are both, in one respect at least, degenerate; the ancestors of the platypus and echidna must have come nearer to the main mammalian stock than do their descendants. The ancestral mammal was assuredly not toothless; yet both the monotreme families are practically devoid of teeth. In the platypus, long regarded as toothless, well-formed teeth were comparatively recently (1889) found by Poulton and Oldfield Thomas embedded in the jaws of the young animal. These are soon discarded: the place of teeth, functionally, is taken by flat, horny plates developed in both jaws, and serving to crush between them the small mussels and similar constituents of the food; in this important function hard, horny plates on the tongue and palate also take a share. But the discovery and close investigation of the structure and development of these rudimentary teeth help to throw light on the question of the relationship of monotremes to other mammals. The teeth are two on each side of the upper jaw, three in the lower, with vestiges of others; they are all grinding-teeth (molars), whose broad surfaces are divided into two main lobes or cusps, with numerous tubercles round the edges.

In *Tachyglossus* teeth are completely absent at all stages: the only tooth-like structure developed in the embryo is the so-called 'egg-tooth' (present also in *Ornithorhynchus*) developed on the upper surface of the snout, and presumably



Teeth of young platypus, in lower right-hand jaw. (View from above—front of jaw at top. x 5)

used for tearing through the egg-shell to enable the young animal to escape. The want of teeth is compensated in somewhat different ways in the two families. In the platypus, as has been said, broad, horny plates are developed in both jaws and the tongue. In *Tachyglossus* there are no horny plates on the jaws, but numbers of little horny structures on the back part of the tongue, working against hard ridges on the roof of the mouth, break up the ants or other insects of which the animal's food is composed. Moreover, the stomach has no digestive glands, and has evidently assumed the character of a gizzard—an organ the function of which is to help not digestively but mechanically in the process of breaking up the food.

Some of the special peculiarities of monotremes may be regarded as adaptations to environment rather than as either primitive or degenerate. Thus in the platypus the webbed feet, the reduced organs of smell with their associated nervous mechanism, and the development of special tactile organs on the beak, are adaptations to an aquatic life: whereas with the burrowing and ant-eating habits of echidnas are correlated the powerful claws, narrow beak, small mouth, and long, protrusible tongue.

With the exception of some remains of two extinct species of *Tachyglossus* and one of *Ornithorhynchus* in the post-Tertiary (Pleistocene) deposits of Australia, the monotremes are not certainly known to be represented by any fossil remains of any age in any part of the world. It has been supposed, however, that the earliest known fossil remains of mammals were remote ancestors of *Ornithorhynchus* and *Tachyglossus*. These remains are grouped together as the extinct order Multituberculata, beginning in small numbers in the Trias of England and Germany, extending in greater force through the Lias of Europe, America, and (perhaps) Africa to the Cretaceous, and dying out eventually, so far as known traces go, in the early Tertiary. The temporary teeth of the young platypus approach more nearly to those of the Multituberculata than to those of any other known form. Hence it is a widely accepted view that these, the most primitive of known mammals, were also primitive monotremes. But evidence which has been comparatively recently obtained, as a result of the study of the skull and other parts of the skeleton of certain American Multituberculata, seems to point to affinities with the diprotodont marsupials rather than with the monotremes.

See J. W. Gidley's notes on the fossil mammalian genus *Ptilodus*, with descriptions of new species, in the *Proceedings* of the United States National Museum, vol. xxxvi (1909). For other general references see MARSUPIALS.

W.A.H.

Moore, MAGGIE (1851-1926), the name by which Margaret Virginia Sullivan, who in 1874 married James Cassius Williamson (q.v.), was for 50 years known throughout Australia and the United States. Born in San Francisco (in the district locally known as 'South of Market') on 10 April 1851, she appeared while still a girl on the local stage, and was in 1873 a member of John McCullough's stock comedy company when J. C. Williamson joined it from New York. At that time Williamson's well-known play *Struck Oil* lacked feminine interest; when Maggie Moore married him, a part was written in for her to sing dialect songs and give imitations of favourite actresses—and within a few years her part was as important to the play as her husband's. Coming with him to Australia in 1875, she shared, and in great measure was responsible for, his successes up to the end of the century; in *Little Nell and the Marchioness* (an adaptation of *The Old Curiosity Shop*) she took the double title-rôle, with Williamson as Dick Swiveller; she was also Mina to his Rip van Winkle. When the company returned to Australia in 1879 she made her own mark independently as Josephine in the first authorized performance of *H.M.S. Pinafore*; in 1882 as the first Australian Bettina in *La Mascotte* (her best singing part), and in 1888 as Meg the Castaway in the play of that name. In 1899 she divorced Williamson, retaining the rights of *Struck Oil*, in which she made many more appearances up to 1912; after the divorce, however, she widened her repertory considerably, and is said to have appeared at one time or another in every form of play except Shakespearian drama. In New York in 1906 she played Gretchen to Thomas Jefferson's Rip van Winkle; she appeared in pantomime in Sydney and Liverpool (England); in Australia after 1914 she was chiefly seen in humorous or dialect rôles of polite or musical comedy. In 1901 she married H. R. Roberts. She was, and remained to the last, one of the most popular actresses on the Australian stage, and her 50th year of association with it was celebrated in Sydney and Melbourne by remarkable demonstrations from her fellow-artists and the public. In 1925 she returned to San Francisco, where on 28 November she was enthusiastically received as the most famous of South-of-Market girls. She died there on 15 March 1926.

Moore, SIR NEWTON JAMES, born at Bunbury in Western Australia on 17 May 1870, and educated at Prince Alfred College in Adelaide, was

articled to Alexander Forrest (q.v.) and trained as a surveyor. He raised the first regiment of mounted infantry in his State, and for seven years (with the rank of major) commanded the 18th Australian light horse. In June 1904 he was returned by Bunbury to the State legislature, joined the Rason ministry in 1905 as minister for lands, succeeded to the premiership in 1906, and held it until 1910. In 1911 he was made agent-general for his State, and since that time has resided in London. During the war he had charge of A.I.F. depots in the United Kingdom, with the temporary rank of major-general. In 1918 he resigned the agent-generalship to succeed Sir George Reid in the house of commons as member for Hanover Square; in 1918-23 he sat for North Islington, and since 1924 has represented Richmond. (C.M.G., 1908; K.C.M.G., 1910.) J.S.B.

Moor-hen. See RAILS.

Moorhouse, JAMES (1826-1915), son of a merchant cutler, was born at Sheffield in Yorkshire on 19 November 1826 and at the age of 16 entered his father's business. A few years later he decided to read for holy orders at St. John's College, Cambridge (B.A., 1853; M.A., 1860). In 1853 he was ordained deacon (priest, 1854), and appointed to the curacy of St. Neots in Hertfordshire; in 1855 he was transferred to Sheffield, in 1859 to Hornsey, and in 1861 to St. John's, Fitzroy-square, London. In the same year he was select preacher to the university of Cambridge, and his four sermons were published under the title *Nature and Revelation.* In 1865 he was Hulsean lecturer at Cambridge. In 1867 he left Fitzroy-square to take charge of Paddington parish, in 1869 was made rural dean of the diocese of London, in 1874 chaplain to the Queen and Warburtonian lecturer, and in 1875 prebendary of St. Paul's cathedral.

In October 1876 he was consecrated bishop of Melbourne in Westminster Abbey, and reached his see in January 1877. There he greatly stimulated church work in the diocese, hastening the erection of many churches and schools, and devoting much zeal to the building of his new cathedral-church—St. Paul's—at Melbourne itself. His influence was felt very widely beyond his own Church; broadminded and eloquent, he attracted men from all denominations; and his advocacy of federation and irrigation, as well as his strong and outspoken views on state education, made him a leader in public affairs. In 1880 he was made chancellor of the university of Melbourne. In 1885, when he was probably the most prominent man in Victoria, and certainly the most notable of the Church of England bishops in Australia, Lord Salisbury offered him the see of Manchester, just vacated by the death of another great bishop, James Fraser. Moorhouse was enthroned at Manchester on 18 May 1886, justifying his desertion of Melbourne by doing even more valuable work in the crowded industrial areas of Lancashire. Entering the house of lords in 1891, he established his position there during the debates of 1902-3 on A. J. Balfour's education bill. But the diocese had worn him out, and in 1903 he retired from active work and lived near Taunton in Devon until his death on 9 April 1915. J.V.C.-B.

Mopoke. See FROGMOUTHS AND NIGHTJARS.

Moraceae, a family of plants closely related to the Urticaceae, from which it has been separated only in recent years. It includes the figs (q.v.), mulberries, and banyans. *Malaisia tortuosa* (Crow-ash) and ranges from Queensland into the Malay Archipelago; its fruits are sometimes used for Christmas decorations. *Pseudomorus Brunoniana* (Whalebone-tree), often called 'crow-ash' in the southern States, is also found in New Caledonia; its hard, tough wood is used by the aborigines for making boomerangs. See CUDRANIA.

Moran, PATRICK FRANCIS (1830-1911), born at Leighlinbridge in Ireland on 16 September 1830 and educated at the Irish College in Rome (where his uncle, afterwards Cardinal Cullen, was rector), was ordained priest by special dispensation (being under the canonical age) on 19 March 1853, and for the next 12 years occupied various chairs in the ecclesiastical colleges at Rome, from 1856 to 1866 being vice-rector of the Irish College and professor of Hebrew at Propaganda. During these years he utilized his ready access to the Vatican libraries to make a deep study of Celtic ecclesiastical history, and in 1864 published *Essays on the Origin, Doctrine and Discipline of the Early Irish Church.* In 1866 he returned to Ireland to be his uncle's private secretary, professor of Sacred Scripture at Cloniffe College, and founder of the *Irish Ecclesiastical Record*; on 5 March 1872 he was consecrated bishop of Olba and coadjutor of Ossory, and on 18 August succeeded to that see. On 21 March 1884 he was translated to the see of Sydney, in which he succeeded Archbishop Vaughan (q.v.), and in 1885 was summoned to Rome by Leo XIII —his lifelong friend—apparently with a view of his being made archbishop of Dublin; after it was found advisable to give this position to Dr. Walsh, Dr. Moran was appointed archbishop of Sydney and subsequently was created cardinal. As primate of Australia he presided over plenary councils in 1885, 1895, and 1905, and visited Rome in 1888, 1898, 1902, and 1903—on the last occasion to attend the conclave which elected Pius X. He died in his palace at Manly, New South Wales, on 16 August 1911.

Cardinal Moran's work in Australia was unceasing and of great value. In his diocese he completed the main section of the new cathedral of St. Mary's (an older one had been destroyed by fire), established many orphanages, hospitals, and schools, and is said to have expended a million and a half sterling on Catholic institutions during his term of administration. He also consecrated 14 bishops, ordained nearly 500 priests, and dedicated more than 500 churches—the cathedrals at Ballarat, Bathurst, Bendigo, Goulburn, Hobart, Lismore, Melbourne, and Rockhampton, as well as that at Auckland in New Zealand, were all either consecrated or dedicated by him. Of even more importance was his foundation of two seminaries intended by him to serve the whole of Australia—St. Patrick's College at Manly, near Sydney, on which he spent £70,000, in order to make it the pan-Australian school for the priesthood, and St. Columba's College at Springwood on the Blue Mountains, ultimately intended to train missionaries for the islands of the Pacific. He was one of the ablest educationists then in Australia, and, while as an extremely militant churchman he repeatedly and vigorously attacked the undenominational system of primary education which prevails in Australia —demanding that Catholic schools should be subsidized by the government on their secular results —he also greatly improved Catholic education by persistent superintendence and reform of the schools under his control.

But he was not content with purely ecclesiastical duties. Though militant to the point of aggressiveness when he thought his Church in danger, he was statesman enough to know how to control his militancy when dealing with secular affairs; and his whole-hearted adoption of Australia as his home led him to take part in many public movements outside his professional sphere. Thus he was an ardent advocate of home rule for Ireland (though he had opposed the Land League agitation), a strong sympathizer with the Australian Labour movement—especially during the maritime strike of 1890—and a persistent and judicious supporter of federation. Sir Henry Parkes—who for other reasons was no friend of the cardinal's—said of him in parliament 'The federal cause has no more earnest, no more eloquent, no more powerful advocate;' and his influence did much to secure the decisive vote in its favour, although he himself was an unsuccessful candidate for election to the convention of 1897-8. Every movement, indeed, that could aid in giving Australia a sense of nationhood received his support; he approved of the despatch of Australian troops to the Sudan, and did his best to educate public opinion up to the establishment of Australian military and naval forces on a scale adequate to the needs of local defence.

As a writer, too, he was noteworthy from his youth up. While still in Europe he published (besides the *Essays* mentioned above) a *History of the Catholic Archbishops of Dublin* (1864) and a *Spicilegium Ossoriense* (1874-84), which valuably illustrate Irish church history. His chief Australian publication was the *History of the Catholic Church in Australia* (1896), which, though awkwardly planned with a division by dioceses, has not yet been superseded or matched; but he also poured out a continuous stream of pamphlets on religious, biographical, and sociological subjects, and edited the *Pastoral Letters of Cardinal Cullen.*

E.M.O'B.

Morehead, Boyd Dunlop (1843-1905), born at Sydney in August 1843, and educated at W. T. Cape's school, the Sydney grammar school, and the university of Sydney, after a few years in the employ of the Bank of New South Wales was made an inspector of Queensland stations for the Scottish-Australian Investment Company, of which his father was the Sydney manager. In 1871 he was elected to the Queensland legislative assembly by the pastoral constituency of Mitchell, and at once took his place as the parliamentary jester; nor was he ever regarded very seriously as a politician. From December 1880 to August 1883 he was postmaster-general in McIlwraith's first ministry, and colonial secretary in his second (June-November 1888); then, mainly because McIlwraith was ill and his colleagues all jealous of each other, Morehead took the premiership, and kept his team together for nearly two years until McIlwraith and Griffith formed their famous coalition. His term of office was made notable by the passage in 1889 of the first Queensland payment of members act and of a very advanced mines regulation act, and by the establishment during that year of a 'record' sitting of the assembly—97½ hours, from 3 p.m. on Monday 28 October to 4.15 p.m. on Friday 1 November. In 1893 Morehead refused the offer of the agent-generalship, and in 1896 was nominated to the legislative council (in which he had sat for a short time in 1880); but he took no further active part in politics, and died at Brisbane on 30 October 1905 .

Moresby, John (1830-1922), second son of Sir Fairfax Moresby who in 1850 was commander-in-chief in the Pacific and arranged the transfer of the Pitcairners to Norfolk Island (q.v.), was born on 15 March 1830 and went to sea as a first-class volunteer at the age of 12 (lieutenant, 1851; commander, 1858; captain, 1864; rear-admiral, 1881; vice-admiral, 1888). He saw active service in the Baltic (1854-5) and China (1861), cruised in Japanese waters in 1864, and in 1871 was appointed to H.M.S. *Basilisk* for service on the Australian station. While cruising off the New Guinea coast in 1873, the idea (to use his own words) came to him to go exploring; and by the end of the cruise he had charted 600 miles of previously unsurveyed (and partly unknown) coast-line, investigated about 160 islands which had previously been thought part of the mainland, and hoisted the British flag at Port Moresby. On return to England he published *Discoveries and Surveys in New Guinea* (1876). In 1879-81 he was senior officer at Bermuda, and retired in 1888. A full account of his life will be found in his *Two Admirals,* published in 1909. He died at Fareham in Hampshire on 13 July 1922. Two of his paintings—an oil showing the discovery of Port Moresby, and a water-colour of the hoisting of the British flag on Hayter Island near Samarai—have been presented to the Royal Australian Navy. In 1914 the admiralty paid him the unique compliment of naming after him the destroyer *Moresby*; no other warship has been named after a living man. His name is also appropriately given to the survey-ship which in 1925 was allotted to work along the northern coasts of Australia. See Papua.

W.J.

Morgan, Sir Arthur (1856-1916), born at Warwick in Queensland on 19 September 1856 and educated at the local state school, was from an early age employed in the office of the *Warwick Argus,* a newspaper owned and edited by his father James Morgan, and afterwards by himself. James Morgan sat in the assembly as member for Warwick from 1870 to 1883, and became chairman of committees; in 1884 Arthur Morgan succeeded him in the seat, and in 1891 in the chairmanship. From 1896 to 1898 he was out of parliament, having been made chairman of a royal commission on local government; but in 1899 he regained the Warwick seat and was at once chosen to be speaker—a post which he held until 1903. When in that year the Philp ministry was defeated on its financial proposals and party government seemed to be disorganized, Morgan accepted the leadership of a coalition including Labour members and seceders from the Philp party, and for more than two years discharged an uncongenial and unpopular duty by carrying on the government through one of the most critical eras in the State's history. By January 1906, William Kidston (q.v.) having established his reputation both as treasurer and as party leader sufficiently to take over the premiership, Morgan resigned his seat, retired to the legislative council, and was made its president. In 1908 he was appointed lieutenant-governor of the State, and administered the government in 1909 and 1914-15. He died at Brisbane on 20 September 1916.

Morgan's premiership produced few important acts, but was of great value as training for the Labour members of the coalition, whose inexperienced eagerness was controlled by him with equal sympathy and judgment. (Kt. Bach., 1907.)

Morgan, Sir William (1829-1883), born in 1829 at Willshamstead near Bedford in England, migrated to Adelaide in February 1849, and for the next 20 years devoted himself to mercantile, mining, and pastoral affairs. In 1869 he entered politics, being elected on 6 August to the legislative council, and in 1871 represented South Australia at an intercolonial conference held in Melbourne to deal with tariffs, a customs union, mail contracts, etc. In June 1875 he joined the Boucaut ministry as chief secretary, but resigned in the following March to attend to private business, and publicly intimated that he would not offer himself for re-election in 1877. During his absence from the colony, however, he was again returned at the head of the poll, took his seat in the council, and was by a vote of its members made its leader during its dispute with the Colton ministry of 1876-7. He took office again as chief secretary in the fourth Boucaut ministry (1877-8), and became premier when Boucaut went to the supreme court in September 1878; his ministry, reconstructed in March 1881, was defeated in June, and he retired from politics. In 1883 he visited England, and died at Brighton on 3 November. (K.C.M.G., 1883.)

Morinda, a genus of the family Rubiaceae, largely tropical, chiefly Asiatic. The flowers are usually united by their bases into small heads; calyx short; corolla cylindrical; fruit a compound succulent mass, composed of the individual fruits. *M. citrifolia* (Leichhardt's Tree or Indian Mulberry) has a bitter granulated fruit, of which the natives of northern Queensland are very fond. In India the green fruit is used in curries. The root yields a yellow and the bark a red dye, used by Polynesians, and in India, to colour materials. The wood has a musk-like odour, and a pleasingly wavy grain.

Morphett, Sir John (1809-1892), born in London on 4 May 1809 and trained for a commercial career, in 1835 purchased land in the projected colony of South Australia and on 20 March 1836 left England in the *Cygnet* with a number of officials and government employees. Reaching Kangaroo Island on 11 September, he took the first opportunity of establishing himself as a merchant in the embryo Adelaide, which he helped Colonel Light to lay out. He at once became prominent in public work, joining the committee for the protection of aborigines, founding the mechanics' institute and the first local insurance company, exploring the Fleurieu Peninsula south of Adelaide, and giving sound advice to intending colonists. In 1840 he was made treasurer of the Adelaide corporation. In 1843 he was nominated by the governor to the first legislative council, was renominated in 1851, and was speaker in 1851-5. Under the constitution of 1857 he was elected to the legislative council, was re-elected in 1865, and held the seat until 1873, when he retired from politics. For five months in 1861 he was chief secretary under Thomas Reynolds; he had never been a party politician, and in the former council his chief interests had been council reform, state aid to religion, and anti-transportation, and he joined no other ministry, but in 1865 was chosen president of the council. He was a lover of horses; in 1837 he owned one of the two that constituted the colony's whole stock, and in 1838 entered a horse for the first races held in South Australia, in succeeding years often riding his own entries. In 1844 he helped to found the Royal Agricultural Society of South Australia. From 1873 onwards he lived in retirement, and died at Glenelg on 7 November 1892. (Kt. Bach., 1870.)

Morris, Edward Ellis (1843-1902), born at Madras on 25 December 1843, and educated at Rugby and Lincoln College, Oxford (B.A., 1866; M.A., 1869), after holding assistant-masterships at Radley and Haileybury and a headmastership in Bedfordshire, was in 1875 made headmaster of the Church of England Grammar School at Melbourne. In 1883 he was transferred to the chair of modern languages and literature in the university of Melbourne, and held it till his death. He took great interest in library work, established a library (named after him) at the grammar school, and in 1879 became a trustee of the Melbourne public library, which by increasing to the utmost the technical and Australian sections and by establishing a lending branch he endeavoured to make 'a university for the people.' He was also very active in the formation of societies—not only of a literary nature, for the charity organization society of Melbourne is of his founding. His literary output, which was considerable, included several historical primers, a memoir of his father-in-law George Higinbotham (1895), and *Austral English,* an excellent dictionary of Australian words, phrases, and usages (1898). He died on 2 January 1902, during a visit to England, leaving behind him an unfinished work, *Cook and his Companions,* to which he had devoted several years of hard work.

Morrison, George Ernest (1862-1920), born at Geelong in Victoria on 4 February 1862, and educated at Geelong College (of which his father was principal) and the universities of Melbourne and Edinburgh (M.D., 1887), while still a schoolboy walked from Queenscliff to Adelaide (500 miles), and on another occasion paddled a canoe down the Murray for 1500 miles. Later he shipped as a seaman (but for journalistic purposes) on board a schooner engaged in the kanaka trade between Queensland and the South Sea islands. At the end of 1882 he walked from Normanton on the Gulf of Carpentaria to Geelong (2000 miles), and in 1883 led a pioneer expedition to New Guinea and was speared in the head and abdomen. Visiting England in 1883, he studied at Edinburgh, and practised as a surgeon for three years. Afterwards he travelled in the United States and Jamaica, and then visited Spain (where he acted as medical officer at the Rio Tinto tin-mines), Morocco, and other parts of northern Africa. Returning to Australia, he became resident surgeon at the Ballarat hospital, but in 1894 went to Japan, and, after traversing the islands, crossed to China and commenced his famous journey across that country—up the Yangtze valley and through Burma to Rangoon. In 1895 he published *An Australian in China; being the Narrative of a Quiet Journey across China to Burma.* This book attracted the attention of Moberly Bell, then manager of *The Times,* who engaged Morrison as *Times* correspondent, first in Siam, afterwards in Peking—a post which he held until 1912. In 1896 he journeyed from Bangkok round Tongking to Yunnan City in China, and in 1897 from Stretensk in Siberia to Vladivostok. His services during the 'Boxer' war (when he was reported killed, and had the pleasure of reading in *The Times* a highly eulogistic obituary notice), and through the succeeding troubles and wars in China, were of exceptional value to the British foreign office

as well as to his newspaper. In 1910 he rode from Honan City in central China to Andijan in Russian Turkestan—3750 miles in less than six months. In July 1912 he was appointed political adviser to the president of the Chinese republic, and exerted valuable influence on the foreign policy of the country during the war of 1914-18. In 1919 he revisited England, and died there on 30 May 1920. Morrison was one of the ablest journalists of his time, with an almost uncanny prescience of events in Far Eastern politics, largely due to his personal knowledge not only of the big seaport towns but of every province of China except Tibet. His library, which was a remarkably comprehensive collection of the world's literature connected with China, he sold before his death to a Japanese statesman.

J.V.C.-B.

Mort, THOMAS SUTCLIFFE (1816-1878), born at Bolton in Lancashire on 23 December 1816, was trained for a commercial career in Manchester, and in 1838 reached Sydney, obtaining employment with Aspinall, Brown & Company as a clerk and salesman. In 1841 he helped to form the Hunter River Navigation Company, which later developed into the Australasian United Steam Navigation Company (see SHIPPING). The Aspinall firm collapsed in the financial crisis of 1842, and in 1843 Mort started independently as an auctioneer and wool-broker, and began to experiment in exporting cured animal food to England. This project, however, failed, and it was many years before he revived it. In 1845 he initiated the famous firm of Mort & Company, whose methods enabled the small grower to realize on his wool quickly. In 1849 he promoted the first line of railway in New South Wales—between Parramatta and Sydney—and, when the gold-fever began in 1851, formed the first Australian gold-mining company, the 'Great Nugget Vein Mining Company.' In 1854, recognizing the necessity for a large dock at Sydney, he commenced the excavation of the largest dock in Australia (see MORT'S DOCK).

In 1856 he took up agriculture, and established in the southern coastal district of New South Wales the Bodalla farm (14,000 acres, later increased to 38,000), which had a great influence on the development of Australian dairying. In the early sixties he floated the Peak Downs Copper Mining Company in Queensland and the Waratah Coal Mining Company in Newcastle, and in 1863 enlarged his docking business, excavating at Balmain a dry dock from which, at a later date, was launched the *Governor Blackall,* the largest steamer built in Port Jackson up to that time (see SHIPBUILDING). He also established a shipyard and works for the manufacture of steam engines, railway carriages, and machinery; this developed into the well-known Mort's Dock and Engineering Company. In 1873 he offered his workmen shares in the business, and all the foremen became shareholders. In 1870 he began a series of experiments in freezing and thawing meat with a view to repeating his earlier attempt to send it to England, and in 1875 established a slaughter-house and freezing-works at Lithgow, and ice-works at Darling Harbour. He chartered the first steamer for the frozen-meat trade and invested £80,000 in the venture, squatters contributing £20,000; but the refrigerating machinery broke down during the voyage, and the failure prevented further experiments; he therefore converted his freezing-works into ice-factories. Just as his cherished idea of sending frozen meat abroad was accomplished he died at Bodalla on 9 May 1878.

In June 1883 a statue, executed by Pierce F. Connolly in Florence, was erected to his memory in Macquarie-place, Sydney, and unveiled by the then governor, Lord Loftus.

Mort's Dock, established by T. S. Mort (q.v.) at Balmain near Sydney in 1854, was in 1872 taken over by the Mort's Dock and Engineering Company; in 1889 an area at Johnstone's Bay (now the Jubilee dock) was added; in December 1901 a dockyard was opened at Woolwich on the Parramatta River, and in 1924 an area at Waterview Bay in Balmain was taken over. The business now includes two graving-docks, four floating docks, four slips, and six separate engineering establishments. The original Mort's dock is 640 feet long, with a breadth of 49ft. 6in. on the sill and a depth on the sill of 18 feet at high water and 14 at low water of ordinary spring tides; it is equipped with an intermediate caisson, and can dock two vessels of an aggregate length of 615 feet at the same time. The Woolwich dock is 850 feet long and 75 feet wide at the sill, having a depth on the sill of 26 feet at high water and 22 at low water; the pumping-plant is capable of discharging 4,000,000 gallons of water per hour, emptying the dock in about two hours. At Waterview Bay there are two floating docks, and two at the Jubilee dock; the largest (at the Jubilee dock) is 320 feet long with an entrance breadth of 50 feet at the top, and is capable of lifting vessels up to 1100 tons. Of the slips three are at Balmain, the company's headquarters, and the fourth at Waterview Bay; the largest, at Balmain, has a length over blocks of 270 feet, a breadth of 36 feet, and is equipped to lift vessels up to 1500 tons. The iron-foundry at Balmain contains cupolas capable of melting 20 tons of metal per hour, blowers, loam-mill, core-making machinery, three travelling cranes (one of 30 tons), and two reverberatory furnaces each capable of handling six tons of metal; the brass-foundry has a 4-ton reverberatory furnace installed to meet the requirements of large steamers for manganese and phosphor-bronze propeller-blades; in the blacksmith shop (which contains 50 hearths) the largest steam hammer is capable of handling blooms up to 36 inches in diameter; the lifting equipment includes a 65-ton sheerlegs and a 10-ton cantilever crane with an effective radius of 140 feet.

Morwell. See YALLOURN.

Morwong, an excellent food-fish (*Dactylopagrus morwong*) of the family Cheilodactylidae, which occurs on the coasts of southern New South Wales, Victoria, Tasmania, and New Zealand. It principally frequents off-shore grounds, and considerable numbers are taken by trawlers; before their advent the market supply was very intermittent, as the only specimens captured were by fishermen using hand and long lines in quest of snapper. Although it may attain a length of two feet six inches, the morwong is not regarded by line-fishermen as a first-rate sporting fish. A squid or fish bait is taken readily.

T.C.R.

Mosquitoes, insects of the family Culicidae; about 100 species, classified in 35 genera, have been described from Australia. Their habits, especially that of acting as hosts to

various pernicious disease-germs, make them both obnoxious and highly interesting to mankind.

The classification of the mosquitoes cannot be regarded as settled. The system based on scale-structure has been largely superseded by a classification based on structural differences, and Edwards has placed a large number of Australian species under *Ochlerotatus,* sinking a number of smaller genera. Under the existing scheme two sub-families, Anophelinae and Culicinae, occur in Australia. The former are represented by five species, *Anopheles stigmaticus, A. atratipes, A.* (*Myzomyia*) *annulipes, A.* (*M.*) *amictus,* and *A.* (*M.*) *bancrofti. A. annulipes,* commonly found all over Australia and extending to Papua, is almost certainly the carrier of the parasites of malaria. *A. bancrofti,* widely distributed in northern Australia, may also be a malaria-carrier (see BANCROFT, JOSEPH, NEMATHELMINTHES, PUBLIC HEALTH, and TROPICAL MEDICINE). The other species are rare and probably of little significance.

The Culicinae include the majority of our genera. Of special medical interest are *Culex fatigans,* the intermediate host of *Filaria mansoni,* and *Aedes argenteus* (*Stegomyia fasciata*), which, besides being the carrier of yellow fever in other lands, has been lately proved by J. B. Cleland to be the carrier of dengue. Both these species breed in and round houses. Other annoying species are *Ochlerotatus vigilax, O. occidentalis, Scutomyia notoscripta, Mucidus alternans* (Scotch or Hexham Gray) and *Culex sitiens. Toxorhynchites speciosa,* the handsomest of all Australian mosquitoes, is a non-biter.

Mosquito larvae are the favourite food of several Australian fishes, notably the Blue-eye (*Pseudomugil signifer*) and Freshwater Sunfish (*Melanotaenia nigrans*) among the Atherinidae and the Carp-gudgeon (*Carassiops compressus*) and Fire-tailed Gudgeon (*C. galii*) among the gobies. Where these natural enemies are not available, the pest may be minimized by covering the pools in which the larvae breed with a thin film of kerosene (which blocks their spiracles) or by dosing the pools with a very small amount, sometimes as little as one part in a million, of copper sulphate, which destroys their food. The surest preventive, of course, is to fill up the pools and do away with all patches of stagnant water.

R.J.T.

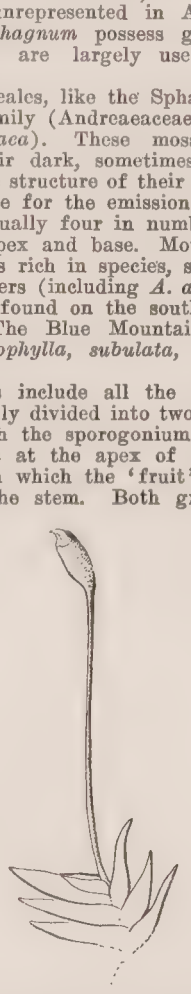
Mosses. The moss-flora of Australia is remarkably varied in its range, and consists of many hundreds of species belonging to nearly 200 genera.

Life-history.—Mosses (Musci) and liverworts, q.v. (Hepaticae) are cellular cryptogams, and are known to science as Bryophyta, as distinct from the Pteridophyta (ferns), which are vascular cryptogams. Mosses are characterized, like the ferns, by alternation of generations; but, unlike the ferns, the plant itself bears the male and female flowers, sometimes at the root, more generally in the leaf-axils, or at the apex of stem or branch. The spore develops into a thread-like growth (protonema), which produces plant-buds. From the female flower (archegonium) arises, by fertilization, a special organ (sporogonium), consisting of a spore-capsule (theca), which is either sessile, or raised on a shorter or longer stalk (seta). In growing, the sporogonium bursts the archegonium and carries the upper part with it as a veil (calyptra) which is often, as in the case of *Dawsonia polytrichoides,* a beautiful and distinctive object. The capsule is either entirely closed, as in the cleistocarpous mosses, or furnished with a lid (operculum). The operculate mosses cast their lids, when ripe, to allow of the emission of their spores, whereas the cleistocarps burst irregularly. The mouth of the operculate capsules is often furnished with one or more series of teeth (peristome), which are regular in number (4, 8, 16, 32, 64), richly coloured and most variously constructed. The calyptra, operculum, capsule, and seta are most varied in their character; the leaf-structure of mosses shows an even more bewildering variation. The spores usually grow from a columella within the capsule.

Classification.—The modern classification of mosses is not based upon any one character, though the fructification is a factor of much importance. Three sub-classes are recognized: (1) Sphagnales (bog-mosses), (2) Andreaeales (alpine or sub-alpine rock-mosses), and (3) Bryales (mosses proper). The Sphagnales consist of one family only, Sphagnaceae, represented by one genus, *Sphagnum,* with some 30 recorded species in Australia. Of the ten sections into which *Sphagnum* is divided, six (notably *Acutifolia*) are unrepresented in Australia. The species of *Sphagnum* possess great absorbent qualities, and are largely used for surgical dressings.

The Andreaeales, like the Sphagnales, consist of a single family (Andreaeaceae) with but one genus (*Andreaea*). These mosses are easily known by their dark, sometimes nearly black, colour, and the structure of their capsules, which split lengthwise for the emission of the spores, the valves (usually four in number) remaining attached at apex and base. Mount Wellington in Tasmania is rich in species, several of them European; others (including *A. australis* and *A. asperula*) are found on the southern ranges of Australia. The Blue Mountains provide *A. tenera, amblyophylla, subulata,* and *subulatissima.*

The Bryales include all the mosses proper. They are usually divided into two groups: Acrocarpi, in which the sporogonium (the so-called 'fruit') grows at the apex of the plant, and Pleurocarpi, in which the 'fruit' grows out of the side of the stem. Both groups are well



Fissidens rigidulus.

represented. The Acrocarpi vary from the tiniest ground-mosses, like *Ephemerum* or *Acaulon,* up to the majestic *Dawsonia superba,* 12-24 inches

in height. A number of the smaller acrocarps are cleistocarpous, and these are sometimes made a separate sub-group; but on the ground of their general structure it is better to regard them as primitive members of the various acrocarpous families. Dr. F. V. Brotherus enumerates 21 families, of which all, except four or five, occur in Australia. Of these the most richly represented are the Dicranaceae, Fissidentaceae, Pottiaceae, Orthotrichaceae, Funariaceae, Bryaceae, and Bartramiaceae. The Dawsoniaceae in addi-

Hypnum crinitum.

tion to their remarkable structure are almost exclusively Australasian. In the group Pleurocarpi we have a wide range of genera and species, of which many, flourishing in the 'rain-forests' of north-eastern Queensland, are tropical in char-

Hypnodendron spininervium.

acter. The scientific order of the families represented is as follows:—Erpodiaceae, Hedwigiaceae, Cryphaceae, Leucodontaceae, Cryptopodiaceae, Lepyrodontaceae, Echinodiaceae, Ptychomniaceae, Neckeraceae, Lembophyllaceae, Entodontaceae, Fabroniaceae, Hookeriaceae, Hypopterygiaceae, Helicophyllaceae, Rhacopilaceae, Leskeaceae, Hypnaceae, Sematophyllaceae, Brachytheciaceae, Hypnodendraceae.

See W. J. Hooker's *Musci Exotici* (1818-20); J. D. Hooker's *Flora Antarctica* (1844-7), *Flora Tasmaniae* (1860), in which the mosses are described by W. Wilson; Warnstorf's *Sphagnologia Universalis* (1911); Paris's *Index Bryologicus* (1893-8) with Supplement (1900); and the works of the following Australian bryologists published in various scientific journals—F. von Mueller, C. Mueller (Victoria), W. A. Weymouth, L. Rodway (Tasmania), F. M. Bailey (Queensland), R. Tate and J. Stirling (South Australia), W. W. Watts, and T. Whitelegge (New South Wales).

Moths. The classification of moths is dealt with under LEPIDOPTERA. This article treats only of their economic importance.

The most serious pest of fruit-trees in Australia is undoubtedly the introduced Codling-moth (*Carpocapsa pomonella*), which, if allowed to breed unchecked, may destroy every apple, pear, and quince in an orchard, and is also a serious pest of the plum, peach, and other stone-fruits. On the mainland it is at least double-brooded, and three broods have been reported. In Tasmania it is single-brooded, and this is one reason why apple-culture is specially successful there; another is that prohibition of the sale of infected fruit is rigidly enforced, so that the pest can be kept within reasonable bounds by proper treatment, and especially by the use of arsenate of lead just after the petals have fallen. It has been estimated that the codling-moth destroys 10 per cent of the apples grown, and, but for the remedial measures taken by orchardists, would take 40 per cent.

In parts of eastern Australia stone-fruits are attacked by larvae of *Conogethes punctiferalis* (Peach-moth), which also bore into maize-cobs after the manner of *Heliothis armiger*, mentioned below. The moth itself is bright yellow, with numerous small black spots.

A serious enemy of the grape in New South Wales and Victoria is *Agarista glycine* (Vine-moth) whose many variegated larvae (growing to a length of 1½ inches) often defoliate vines. The moth is black, prettily marked with yellow and orange, and has several broods in a year; it also attacks the Virginia creeper and other vines, and fuchsias. The Hawk-moth (*Chaerocampa celerio*) also attacks grape-vines throughout Australia. The larvae of this beautiful moth grow to a length of four inches, and are so numerous at times that the ground beneath them is covered with their dung-pellets; fortunately they are kept in check by natural enemies (*Tachinia* flies and ichneumon-wasps).

Among the most curious of fruit-attacking insects are the orange piercing moths (Ophiderinae) whose proboscis is acutely tipped and barbed with a hard boring apparatus, enabling them to pierce the skin of oranges, bananas, mangoes, and grapes, which then fall prematurely in a damaged condition. Three species (*Othreis fullonica, Macnas salaminia,* and *Argadesa materna*) are widely distributed not only in Australia, but over a wide range of the Indo-Malayan region.

The Emperor Moth (*Antheraea eucalypti*) attacks gum-trees and pepper-trees, as well as apple and other fruit-trees. Its large caterpillar (green, with blue-tipped processes) consumes several times its own weight of food in a day, but shares with the hawk-moth larva several efficient natural enemies; a case is on record from Tasmania in which nearly 600 small ichneumon-wasps were reared from a single emperor-moth larva—which yet had sufficient energy to form a cocoon.

The Cherry-tree Borer (*Cryptophaga unipunctata*) is a native moth whose larva originally fed on species of *Acacia* and *Banksia*, but has transferred his attentions to cherry, apple, pear,

quince, nut, hawthorn, willow, elm, and other useful trees; gum may often be seen oozing from the holes he bores. A widely distributed native moth that has become a serious pest is *Cacaecia postvittana*, of which the adult is pale brown, with variable markings; the larva is a pale, dingy green, and, when feeding, joins two leaves (or a leaf and a fruit) for a hiding-place. It disfigures apples, stone and citrus fruits, grape-vines, currants, walnuts, tomatoes, asparagus, beans and peas, besides such garden-plants as the dahlia and chrysanthemum. It is also injurious to stored apples, in which eggs or young larvae may have been allowed to remain. Case-moths (Psychidae) abound in all timbered parts of Australia, and are sometimes so numerous on apple-trees that poison-sprays must be used. The larvae devour leaves and bark, and when approaching maturity spin round a twig a silken girdle which kills it. The females are wingless, and never leave the cases. Those of a Queensland species of *Metura* construct bags almost a foot long. Few birds will eat them, but they have many parasites. The mating-habits of some species are curious.

In Tasmania and eastern Victoria the Underground Grass-grub (*Oncoptera intricata*) sometimes occurs in such numbers that thousands of acres are stripped of all fodder-plants. The grub constructs, and lives by day in, a cylindrical burrow a foot or so in length, lined with silk; it comes out at night to feed. The rarer female seldom flies. The males fly actively at night; it is not unusual to see a mass of males, the size of a cricket-ball, struggling round one female. Among its many insect enemies the most useful is a small ant (*Pheidole tasmaniensis*), the workers of which collect thousands of the eggs and store them in small pockets in their nests. As the larvae hatch, they are eaten, and the empty shells are taken outside the nests.

Many large and beautiful 'timber-moths' of the genera *Charagia, Hepialus, Oenetus, Leto,* and the more soberly coloured *Zeuzera,* have larvae which bore into the solid wood of forest trees. Only one (*Charagia lignivora*) has been recorded as attacking apple-trees in Victoria, South Australia, and Tasmania. The male is green, with white markings on the front-wings; in the female the white is replaced by reddish markings, the hind-wings being also reddish.

One of the most destructive of the 'hairy caterpillars' is the larva of *Teia anartoides,* which skeletonizes the leaves of the apple and pear, and nibbles patches of skin from the fruit. The male moth is yellow-and-brown, with variegated markings; the wingless female is uniformly brown. A white moth (*Porthesia hololeuca*) has a hairy larva, smaller and more variegated than that of *Teia,* which also nibbles apples as well as the bark of young shoots. A larger 'woolly-bear' larva—without any special bundles—feeds on grasses and many garden-plants; the moth (*Artices glatygnii*) is white with brown markings, reddish beneath. The larvae of species of *Teara* (*interrupta, contraria,* and others) live in communities in silken bags or 'tents' which range up to 10 by 8 in., and weigh, with their contents, several pounds. By day they remain in the bags, among cast skins and excreta, coming out to feed by night, always marching in single file, each touching the one in front. As they grow older the hairs drop out; consequently cattle do not like feeding beneath trees on which bags are abundant, and

(A approximately twice, B three-quarters, C, D, E three times natural size.)

some actually die from inflamed mouths. Stockmen cutting such trees for feed suffer severe irritation due to the penetration of the hairs into exposed parts. The females have a dense tuft of hairs at the tip of the abdomen, used to cover up the eggs. They are especially destructive to myall and yarran.

Pinara nana, a pale yellowish-brown moth, has curious woolly white larvae, often seen on apple and apricot trees, where, pressed closely to the twigs by day, they resemble clumps of lichen. At night they eat the bark, leaves, and fruit and, when fully grown, spin a flimsy white cocoon. Another species spins a large green cocoon. All the species may be found on eucalyptus trees. Hairy caterpillars are subject to parasites, but seem to be avoided by birds—except by cuckoos, whose stomachs are frequently found crammed with their remains.

Cutworms are night-feeding larvae of noctuid moths, which remain underground by day; they cut off plants level with the ground, and by their attacks on vegetable and grain-producing plants probably do more damage than all other insects combined. In the Tamworth district of New South Wales a crop of 1000 acres of English barley, which afterwards yielded between 30 and 40 bushels per acre, was attacked by millions of cutworms, and was saved by an expenditure of £97.

The Bugong Moth (*Euxoa infusa*, formerly known as *Agrotis spina*) in some years appears in countless numbers, delaying trains in tunnels (because the crushed bodies make the rails greasy), sometimes obscuring the lantern of a lighthouse, and annoying suburban householders by an abnormal destruction of gas-mantles. The larvae destroy grass and cereals over extensive areas. The aborigines used to make periodical trips to the Australian Alps to gorge on this delicacy. Here in rock crevices and caves they occur in masses (hence the name Bugong—or Bogong—Mountains).

Another species (*Euxoa radians*, also known as *Agrostis munda*) is a serious grape-vine pest which, before bait-laying and spraying were adopted, did immense damage in Western Australia by devouring the young bark, buds, and leaves. Skins of potato-plants and hop-vines are partly eaten through and die; swedes and turnips are gnawed, and many garden-plants (especially carnations) attacked. The larva, of a dingy earth-colour, is not easily noticed, so that the damage it commits is often attributed to other causes.

The striped larvae of *Mamestra ewingi*, found in Tasmania, attack cereals (also potatoes), nipping off the heads so that the crop seems to have been stripped. These caterpillars march in armies in one general direction. In 1919 this species and the bugong ravaged many acres of wheat in South Australia in early spring, the ground being left bare. Like most noctuids, both are cannibalistic when green food is deficient; if the available crop has been destroyed before they are full-fed, they devour each other, so that the second brood is generally less destructive than the first. *M. composita* is the moth whose larva is often seen in tomatoes, which it destroys in the same way as the larva of the maize-moth. The introduced *Leucania unipunctata* and *Spodoptera exempta* occasionally appear in masses. The silvery *Phytoraelia argentifera*, with its ally *P. chalcytes*, are serious enemies to tobacco-plants, beans, peas, and especially potatoes; the green larvae, in appearance almost like looper caterpillars, feed day and night, swarming over the plants in countless numbers. Fortunately they are attacked by bacteria which in some years almost exterminate them, and are further subject to insect-parasites.

Second only to the codling-moth among introduced pests is the Maize-moth (*Heliothis armiger*), the notorious cotton-pest of America. Here its striped larva bores into maize-cobs, pea-pods, tomatoes, apples, and other fruits, and few cultivated plants are free from it. Against 'army worms' poison-baits and sprays are sometimes used. An effective poison is made by mixing a small handful of paris green with a pound of dry bran; this is moistened when required for use and a pinch of salt added to each little heap which is laid among the plants liable to be attacked. A plan commonly adopted is to plough a furrow across the line of their march, and at intervals dig pits about 3 feet deep therein. The larvae seldom crawl beyond, but proceed along the furrow into one of the pits, where from their cannibal habits they are soon destroyed. In potato-crops special sled-like crushers have also been used; these are drawn along a furrow by a horse, and combine the destruction of caterpillars with the 'hilling' of the rows.

Looper caterpillars (Geometridae), represented in Australia by hundreds of species, have, fortunately, little taste for garden-plants, though many eat fodder-plants. Thus *Lophodes sinistraria* attacks the apple, apricot, and runner-bean, and *Phrissogonus pyretodes* bores shot-holes in apples and cherries.

In Norfolk Island the sweet-potato crop is, in some years, almost destroyed by the larvae of the small Convolvulus-moth (*Bedellia somnulentella*). On convolvulus plants this moth bores between the skins of the leaves, covering them with spider-like webbing.

Tree-lucerne is commonly attacked by the beautifully marked *Mecyna polygonalis*, a comparatively recent introduction. The dried-fruit moths, *Ephestia cahiritella* and *Plodia interpunctella*, are to be found in most grocers' shops throughout Australia; currants, dates, dried figs, apricots, etc., are seldom free from them, and nuts are also attacked. The Mill-moth (*Ephestia kuehniella*) attacks all kinds of meal. The best antidote so far appears to be the application of heat. The small *Lita solanella* attacks growing potatoes and tomatoes, and often stored potatoes, the grub entering and destroying the eyes. Tobacco-leaves are also reduced in value by its depredations. The Cabbage-moth (*Plutella cruciferarum*), as well as *Hellula undalis*, attacks cabbages, cauliflowers, turnips, radishes, and other crucifers, riddling the leaves and covering the heart of the plant with webbing and excrement.

Tinea granella, *Sitotroga cerealella*, and *Pyralis farinalis* (grain-moths) are three introduced pests that destroy wheat and maize, especially frequenting the lower parts of wheat-stacks.

The Greater (*Galleria melonella*) and the Lesser (*Achroea grisella*) Bee-moth are now widely distributed throughout Australia. Owing, however, to the improvements in modern hives, they are comparatively easy to control. *Achroea* has been noticed in wasp-nests on the Richmond River.

The chief friends of the agriculturist are birds, many of which feed on insect pests. Thus the ibis destroys cutworms; magpies, woodswallows, and even cockatoos are known to have kept down grasshoppers. The indiscriminate

use of poison-baits for rabbits tends, unfortunately, to destroy these farmers' friends.

Useful Moths.—Certain moths should be protected as useful destroyers of scale-insects. Thus *Batracheda sparsella* may be seen among masses of *Aspidiotus, Eriococcus,* and *Lecanium,* which they largely destroy. The larger *Thalpochares* species (*T. coccophaga* and *T. pulvinariae*) destroy immense numbers of scale-insects, and construct silken cases to which are attached the external parts of their victims, and under cover of which they move protected from birds.

A.M.L.

Moulton, JAMES EGAN (1841-1909), born at North Shields in Northumberland on 14 January 1841 and educated at Wesley's school at Kingswood near Bath, was apprenticed to his uncle, a Derbyshire chemist, and became organist at the local chapel and a leader among the supporters of foreign missions. In 1862 he was accepted by the Wesleyan conference as a candidate for mission work, and was allotted first to China, then to Fiji; in June 1863 he reached Sydney on the way to his station, but was intercepted and appointed temporarily to the recently established school at Newington near Parramatta (see SCHOOLS). In 1865, when preparing to resume his voyage to Fiji, he was appointed to the Tonga mission, and reached Nukualofa on 30 May. With this mission he was associated for 41 years, 20 of which he spent in Tonga. In 1866 he founded Tubou College, at once a school, a seminary for ministers, and a training institution for government officials. His introduction of choral singing into this college was hampered by the fact that the tonic sol-fa notation included most of the 'swear-words' in the Tongan language, so that he had to invent a new notation. He also prepared a Tongan grammar, and in 1876 was asked to undertake a new translation of the Bible. That of the New Testament he accomplished during a visit to England in 1877-80. He used the original Greek text as his basis, and thus produced a translation more akin to the Revised than to the Authorized version. On his return he found that a fellow-missionary, Shirley Baker, had mismanaged the mission and resigned his post to become premier of Tonga. In 1885 Baker induced the king to establish a Free Church and a government college with special privileges, and to put pressure on all his subjects to abandon the Wesleyan for the Free Church. The quarrel ended in definite and vehement persecution, the disbandment and looting of Tubou College, and the exile of the remaining Wesleyans to Fiji. The British authorities then interfered, peace was nominally restored, and the college was reopened. In 1888, to remove the last vestige of friction between the mission and the king, Moulton handed over his post to George Brown (q.v.) and returned to Sydney, where in 1893 (after a visit to England) he was made president of Newington College—transferred to the Sydney suburb of Stanmore in 1880—and president of the Methodist conference of New South Wales. From 1895 to 1906 he was also chairman of the Tonga district (no longer a mission), and in 1902 completed an exceptionally valuable translation of the whole Bible. His presidency of Newington College (1893-9) fell in years of great difficulty. The financial disasters of 1892 were a heavy blow to Newington and to other schools; but his courage was unquenchable; valuable additions to the school equipment still remain as his memorial. In 1906 he retired from active work, and died at Lindfield near Sydney on 9 May 1909. See his son's *Moulton of Tonga*; and for sidelights on the Baker episode Basil Thomson's *Diversions of a Prime Minister* (London, 1894); and *George Brown; an Autobiography* (London, 1909).

A younger brother, JOHN FLETCHER MOULTON, after a successful career at the bar was in 1906 made a lord justice of appeal and in 1912 raised to the peerage as Baron Moulton of Bank and made a lord of appeal in ordinary. His scientific acquirements were of exceptionally wide range. He was a fellow of the Royal Society and of the Royal Astronomical Society, a president of the Institute of Gas Engineers and of that of Chemical Manufacturers, and during the war of 1914-18 was director-general of explosives in the ministry of munitions. Another brother, WILLIAM FIDDIAN MOULTON, was the first headmaster of the Leys school at Cambridge, and in 1870-81 one of the revisers of the New Testament; and William's son, JAMES HOPE MOULTON, was a learned Egyptologist and an authority on Zoroastrianism.

J.C.

Mound-birds, birds of the family Megapodiidae and order Galliformes (fowls and game birds). Megapodes are peculiar to the Australian region, occurring in Australia, the Pacific islands as far east as Samoa, and the Malay Archipelago west to Lombok, Celebes, and the Philippines. One species, closely allied to one in the Moluccas, is found in a wild state in the Nicobar Islands in the Indian Ocean; it was almost certainly introduced there by the Malays, who frequently keep these birds in captivity. Three species occur in Australia, the scrub hen, mallee hen, and brush turkey.

Megapodes differ from all other birds, and resemble reptiles, in the method by which their eggs are hatched. These are deposited in mounds of earth, sand, and vegetable matter, and hatched by the heat of the sun—more or less aided by heat due to decomposition of the vegetable matter in the mounds. Though the three Australian species differ somewhat in their habits, the main features of their behaviour in regard to the construction and care of their incubating-mounds appear to be the same. The mound is constructed largely or entirely by the male bird, who begins to scratch up material some months before the breeding-season. The first season's mound is a comparatively small heap, but as it is added to year after year it may in time assume very large dimensions. Each female probably lays from 9 to 15 eggs in a season, at intervals of about three days. Sometimes three or four females lay in the same mound, so that it may contain over 40 eggs. The female deposits her egg in a hollow which she scratches out in the mound. The eggs, which resemble those of the domestic fowl, but have very thin shells, are very large in proportion to the size of the bird. As soon as an egg has been laid, the male places it in an upright position by pressing material of the mound round it with his bill or feet. The smaller end of the egg is invariably placed downwards, and the eggs are often arranged in irregular circles of about six or eight, those first laid forming the lowest ring with other rings above, but the eggs in the higher rings are never vertically above those in the lower levels. Incubation apparently lasts for about two months, but varies considerably according to the temperature and humidity of the mound.

While incubation is in progress the birds are never far from the mound, and constantly work at it, opening it up to admit sunshine or moisture as required or banking it up in unfavourable weather. By these means a temperature of about 95° F. is maintained in the interior of the mound. By the time the chick is ready to emerge from the egg, the shell has become very fragile and easily breaks. The chick gradually scratches its way to the surface, possibly in some cases assisted by the parents, but apparently it usually remains for some hours in the mound. Though the body of the newly-hatched chick is covered with down, the quill-feathers of the wings are already large, and it is capable of flight almost immediately after it reaches the surface. Its legs also are strong, and it at once starts to scratch for food and lead an independent existence, the care of the parents being entirely devoted to the incubator.

The Scrub Hen, or Scrub Fowl (*Megapodius reinwardt*), inhabits the tropical scrubs of the coastal districts of northern Australia, from the Kimberley district of Western Australia to the Byfield district on Keppel Bay in Queensland. It occurs also in the Aru Islands and New Guinea. The back and wings are olive-brown, the neck gray and the under-parts and crown of the head fuscous. The feathers on the crown are elongated to form a sort of crest. The bill is reddish-brown and the legs orange-red. The scrub hen is the smallest of the three Australian megapodes, measuring from 14 to 18 inches in length, but it forms the largest mounds. These are often 10 feet high and 70 feet in circumference, and frequently much larger; a specially large one has been estimated to contain 297 cubic yards of material weighing approximately 300 tons. They are composed mainly of soil and sand, and when old mounds have become consolidated, and trees have grown upon them, it is often difficult to believe that they are the work of birds and not natural hillocks. The breeding-habits of this species are not so well known as are those of its congeners, but it would appear that the eggs, which are buff-pink in colour, are deposited irregularly in the mounds at the ends of tunnels scratched out by the females and afterwards filled up with vegetable debris. Occasionally single eggs are placed in holes in the ground, made by the birds when searching for food in accumulations of leaf-mould.

The scrub hen is almost completely terrestrial, generally trusting to its legs to escape from danger, though occasionally it will fly in laboured fashion into a low branch of a tree. It is a noisy bird, uttering loud harsh calls, especially at night. Its food consists almost entirely of insects, centipedes, worms, etc. obtained by scratching among the debris on the ground in the scrubs.

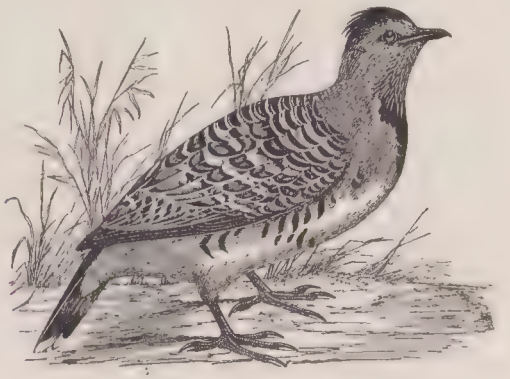
The Brush Turkey or Scrub Turkey (*Alectura lathami*) inhabits the scrubs of eastern Australia from Cape York to the Illawarra district in southern New South Wales. It occurs not only in the tropical scrubs and subtropical brushes of the coastal districts, but also in the softwood scrubs of central Queensland and the brigalow and belar scrubs of western Queensland and north-eastern New South Wales. The brush turkey is much larger than the scrub hen, measuring about 24 inches in length; its plumage is dull black, the feathers on the under-parts being edged with white; the head and neck are devoid of feathers, but are studded with short dark hairs; the skin of these parts is red, and the male has large wattles of bright yellow on the front of the neck; in the female these are rudimentary or absent. Birds from northern Queensland have the lower neck and wattles purplish-white.

The mound of this species is comparatively low, usually only from 2 to 4 feet high with a circumference of about 35 feet. It is composed mainly of leaf-mould, sometimes with a layer of sticks and twigs on the surface. In

Brush Turkey (*length* 24 *in.*).

forming it the birds bring together all the surface debris from a large area surrounding it, scratching the material backwards sometimes for a distance of over 100 yards. The eggs are pure white, but become stained with the earth of the mound. The mounds are generally constructed in shady localities in the scrub, and the heat of the mound is due to the decay of the moist vegetable material, the amount of moisture being carefully regulated by the birds.

Brush turkeys remain on the ground during the day, but roost in trees at night, and also fly up into the trees with a heavy laboured flight when disturbed. Their food consists of fruits and berries, as well as insects, and in many districts they feed largely on the fruits of prickly pear. In consequence they are often shot in Queensland because they are accused of spreading this pest, but experiments with captive birds have shown that the seeds are so much crushed in the powerful gizzard that few, if any, of them are capable of germinating when voided by the birds. The call of this species is a raucous croak and in the breeding-season the male utters a loud 'oom.'



Mallee Hen (*length* 24 *in.*).

The Mallee Hen, Mallee Fowl, or Native Pheasant (*Leipoa ocellata*) inhabits the inland districts of southern Australia (particularly the

mallee and other dry-land scrubs), but occurs also in the coastal forest regions of the south-western corner of Western Australia. It extends as far north as Shark Bay and the Gascoyne district in that State and thence through South Australia to the Broken Hill district of New South Wales, and the Wimmera district of Victoria. It is commonly known by its aboriginal names, 'lowan' in Victoria, 'gnow' in Western Australia. Owing to the clearing of the mallee country for wheat-growing and the destruction of the birds by foxes and sportsmen, mallee hens have now become rare or extinct in many localities where they were formerly plentiful. Some have recently been liberated on Kangaroo Island, South Australia, in the hope that they may survive there when exterminated on the mainland.

The mallee hen is about 24 inches in length and its plumage above is mottled with rufous, brown, and white; there is a black patch on the breast in the male, and the under-parts are dull white. The feathers of the crown, which are fuscous, are elongated to form a sort of crest. The bill is black, the legs bluish-gray. The mound is comparatively low, 2 to 4 feet in height and about 30 to 40 feet in circumference; it is mainly composed of sand but contains in the centre a bed of leaves and other vegetable debris about 8 inches thick. The pale pinkish-buff eggs are placed near together in this bed from which the overlying sand is scratched off in sunny weather and replaced at night or in dull weather, the heat being mainly derived from the sun.

The food of this species consists of insects, seeds, berries, and the tender shoots of plants, and it can subsist without water. It is almost completely terrestrial. Its call is a loud, mournful cooing, uttered with the head between the legs, the back of the head almost touching the ground.

Mountain Hickory. See ACACIA.

Mountain Moss. See LYCOPODIALES.

Mount Morgan, a hill (originally 1267 feet high) in the Dee Ranges of Queensland, 20 miles SSW. of Rockhampton and 10 miles S. of the tropic of Capricorn. Charles and William Archer, on their way from Eidsvold to Gracemere in 1853, passed close to the foot of it, but for nearly three decades longer it was only an insignificant hill in a tangle of peaks and ridges; the nature of its surface, however, was noted, and it was named 'Ironstone Mountain.' In 1870 John Gordon selected 640 acres of Calliungal (No. 2) run, and his western boundary-fence crossed the summit of the mount; in 1878 he transferred the selection to his son Donald, who acquired a freehold title to the block. In 1882 Donald's brother Alexander, who was working for the brothers Morgan at the Galawa mine on the Cawarral goldfield, offered to take his employers to a silver (some say 'copper') 'show' on Calliungal run, and in July Thomas and Edwin Morgan went with him down the Dee River, but failed to find what they were looking for, and on their way back camped, storm-bound, in a hut on Gordon's selection.

Conflicting stories are told regarding Gordon's knowledge of the value of his property. The facts seem to be that, though he suspected the mountain to be auriferous (since alluvial gold had been found all round its foot), he was unaware that gold might occur in ironstone, and had not troubled hitherto to verify his suspicions. When the Morgans arrived, however, he had just arranged to send a drayload of stone from the mountain for a trial crushing. Edwin Morgan, on the other hand, claims that he suggested prospecting round the hut where they camped, and he and 'Sandy' Gordon took samples of the surface stone from the top of the mountain. The brothers then sent Gordon away, and brought a third brother (Frederick) up to their find; it was renamed 'Mount Morgan,' and as much as they could take up of the ground outside Gordon's freehold was pegged out. To raise capital, a half-share in the mine was sold to Thomas Skarratt Hall, William Knox D'Arcy, and William Pattison. This syndicate purchased Gordon's freehold for £640 and erected at the foot of the mountain a battery which recovered only about one-third of the gold in the ore. After trying and rejecting pan amalgamation, the Plattner process, and the Newbery-Vautin process, a local adaptation of the barrel process of chlorination was found successful.

Meanwhile in 1886 the syndicate, which had won 59,024 oz. of gold from the mine, became a limited liability company with a nominal capital of £1,000,000. By this time the Morgans had sold their interest, and several others, including Walter Russell Hall, had bought in.

In 1887 were completed the 'Lower Works,' capable of treating 500 tons of ore per week. In 1888 a second chlorination plant (the 'Top Works'), with a capacity of 1000 tons per week, was erected on the hillside nearer the mine; 880,904 tons of ore were treated in these plants. In both, the crushed and roasted ore was charged into revolving barrels with water, sulphuric acid, and bleaching powder, the barrels were revolved for several hours, and were then discharged into vats from which the gold chloride was washed, to be precipitated on charcoal. This process was slow and expensive, and in 1892 the Hall-Richard process was introduced—the roasted ore being placed in open vats, wetted down, and treated by running on a solution of chlorine in water, which dissolved the gold and carried it to the charcoal filters. The chlorine for this process was generated from salt, pyrolusite, and sulphuric acid made at the mine. Until 1891, when stoping commenced on a very small scale, the ore mined came from open quarries on the summit of the mountain. Development work, however, showed large quantities of low-grade oxidized ore, and of heavy sulphide ore, which existing plants were not able to treat economically; so a new plant was designed to treat low-grade oxidized ores, and was completed in 1898. The process involved crushing, drying, grinding in ball-mills, roasting in revolving furnaces, cooling and leaching in open vats; a full description is given in the *Transactions* of the Australian Institute of Mining Engineers (xv 363). These 'West Works,' which had a capacity of 400 tons per day, ran until 1910 and treated in all 1,500,814 tons of ore.

To treat the sulphide ore, the 'Mundic Works' were completed in 1901. The furnace adopted (partly reverberatory and partly shaft-furnace) was economical in operation, of large output, and gave a dead roasted calcine suitable for leaching. This plant continued in operation until 1912, and put through 1,278,887 tons of ore. The treatment was similar to that fol-

lowed for low-grade oxidized ores, except that the type of roaster was different, and the calcine was given a preliminary acid leach to extract copper before running on the chlorine solution.

The solutions from both works passed over charcoal filters on which the gold was precipitated; this charcoal was burnt off at intervals, and the ash smelted, the rich slag product being sent away for treatment. When copper ore was discovered in the mine in 1902, a circular water-jacket furnace was obtained, as much to treat the accumulated gold slag as to smelt the copper ore; but exploratory drives and diamond drills soon showed the size of the copper orebody, and in 1906 the first furnace of a large smelting-plant was blown in.

Until 1904 all underground ore came from square-set stopes. In that year a flat-back-chamber method of stoping was introduced in the copper body, and followed until 1908, when two falls of ground that killed 12 men caused the resumption of square-set stoping. All the ore that could be reached by the cheaper method of quarrying has been so obtained, and in 1903 steam shovels were introduced to remove overburden. These ceased digging in 1912, but the open cut is now over 400ft. below the original summit, and covers an extent of 15 acres.

In 1912 it was decided that it would be more profitable to give up chlorination, concentrate the siliceous ore, and smelt the concentrate with the more pyritic ore. This entailed the reconstruction of the whole works, and the plant then erected (which commenced to treat ore in 1914) was in operation until 1925. In this plant the ore was separated into concentrating and smelting ore at the main shaft headgear; the concentrating ore was carried on conveyors to the breakers, and thence to the 800-ton mill, whence the concentrates passed to Edwards furnaces, and from them to the Dwight-Lloyd roasters. One of the three water-jacket furnaces (336in. x 56in.) was in operation at a time, and was fed with mine ore, D.L. sinter, limestone flux, coal and coke, brought to the furnace in electric trains. Baralaba semi-anthracite coal was being used in place of part of the coke charge. The matte was converted in basic-lined converter vessels, and the blister produced was shipped to Port Kembla for refining.

In September 1925 this plant was definitely closed down, operations having been carried on at a loss for some years past. In 39 years the works had treated 9,196,605 tons of ore, containing 5,305,979 oz. of gold and 139,427 tons of copper, and had paid £9,379,166 in dividends. It still contains approximately 8,000,000 tons of low-grade ore.

There is no 'reef' at Mount Morgan. The orebody is a mass of silicified quartz-porphyry, irregularly impregnated with pyrite and chalcopyrite (exceedingly variable in its gold and copper contents), intersected by three series of intrusives, and held, as in a cup, by a large intrusive mass of quartz-diorite. The oxidized portion of this body was of such size and richness as to puzzle early geologists, who advanced the now discarded theory of geyser action to account for it.

The town of Mount Morgan is wholly dependent upon the mine, and its population fluctuates with the number of the company's employees, the maximum having been about 16,000 (estimated). The mine is connected with Rockhampton by a rack-line up Razorback with a grade of 1 in 16; the line is continued southward to the coal-field of Baralaba and up the Callide valley. The average rainfall is 30.88 inches, and the mean average temperature 70.7°. To obtain fuel, fluxes, and supplies, the company's operations have extended far beyond Mount Morgan. Limestone came from Marmor, 50 miles away; coal from Baralaba (66), pyritic flux from Many Peaks (150), and ironstone was quarried at Iron Island, 145 miles by sea from Rockhampton.

See Sykes's *Mount Morgan Gold Mine* (1893), Bird's *Early History of Rockhampton* (1904), Rees Jones's *Gold Mining in Central Queensland* (1913), and the annual *Reports* of the company from 1886 to 1925. Notes on the geology of the district will be found in the *Transactions* of the Australian Institute of Mining Engineers (xv. 439 sqq.), and on the petrology in the *Transactions* of the American Institute of Mining Engineers (lv. 263 sqq.).

B.G.P.

Mucuna, a widespread tropical genus of the family Leguminosae, consisting chiefly of climbers. The flowers are large, purple, yellow, or nearly white, in clusters; leaves 3 leaflets; pod thick, clothed with stinging hairs which soon disappear. *M. gigantea*, the only indigenous species, is also common in India and the Pacific islands. The cooked seeds are eaten by the aborigines. The pulverized bark is used in India for rheumatism.

Mudie, JAMES (of whose early years, as of the latter end of his life, nothing is known), was at one time a sub-lieutenant of marines. In 1814 he commenced, and in 1820 published under royal patronage, a *Historical and Critical Account of a Grand Series of National Medals* covering the reign of George III. This ambitious work, which he declared cost him £10,000, proved a financial failure, and Mudie with his family migrated to New South Wales. He arrived in Sydney in July 1822 and received a grant of 2000 acres at Patrick's Plains on the Hunter River; this he named Castle Forbes, in honour of Sir Charles Forbes of London, who had assisted him to migrate. By 1834 (thanks to his son-in-law John Larnach) he had one of the best agricultural establishments in the colony, employing from 50 to 70 assigned convicts in normal times and up to 120 for harvesting. After the arrival of Governor Bourke in the colony the assigned servants at Castle Forbes became less amenable to discipline than formerly—a change which Mudie attributed to the governor's known leniency to convicts. Mudie had no patience with humanitarians, and considered that 'transportation should really be made to operate as a punishment.' In his own words he 'not only kept his convicts in their proper place, and at their proper distance, and compelled them to wear the regular convict dress, but he had the dress of each branded with a number, and with his own name as the assignee master.' Nevertheless the treatment of the servants at Castle Forbes did not seriously contravene colonial regulations.

In November 1833 a party of assigned convicts absconded from the estate and joined with others (also from the estate) who had recently been sentenced to the ironed gangs but had escaped custody; six returned on a robbing expedition and attacked Larnach with intent to murder, and for this five were condemned to death and one was sent to Norfolk Island for life. During the trial the prisoners made such an impassioned appeal against the harsh treatment meted out to them at Castle Forbes that the governor, though not delaying execution, thought it necessary to inquire into

these allegations; he satisfied himself that many of the complaints were ill-founded, but rebuked Larnach for certain proved instances of ill-treatment, and stationed a disinterested resident magistrate in the district to superintend the police. Public interest being roused, Mudie was bitterly attacked by the *Sydney Gazette* in articles which it was generally agreed were written by the sub-editor—William Watt, a ticket-of-leave man; Mudie pursued him with unabated hatred thereafter and repeatedly brought him before the courts, attempting during the trials to show that Watt had the backing of the local government. Bourke thereupon sent Watt to Port Macquarie to be out of the way, and in January 1836 issued a new commission of justices of the peace, from which Mudie's name was omitted.

Convinced that this was a pandering to the convict population, Mudie did not care to return to Castle Forbes, disposed of his property (except a few acres at Maitland), and left for England on 31 March 1836. He had in 1834, after the inquiry at Castle Forbes, issued a pamphlet in vindication of his and Larnach's actions, and had sent a copy to the colonial office. After reaching England he prepared for publication *The Felonry of New South Wales* (1837) 'to expose the convict propensities of the present colonial government;' it is an intemperate attack on certain aspects of Bourke's administration and on prominent colonists who for one reason or another had displeased the author. There are serious defects in the pagination of the *Felonry*, but it is probable that these are merely printer's errors.

In 1837 he gave evidence before the select committee on transportation, denouncing lengthily the depravity of the convicts. In 1839, being desirous of returning to New South Wales, he applied to the colonial office for a grant of 560 acres of land which he had forfeited through a technicality in 1830; this claim was not allowed, nor was an application to take a number of shepherds, agricultural servants, and mechanics to the colony on the bounty system. He reached Sydney on 2 June 1840 in failing health. On 2 September he was horsewhipped in the street by the son of John Kinchela (q.v.). He brought an action for assault, was awarded £50 damages and costs, and then thought it best to leave the colony. Nothing more is known of him.

His sobriquet 'The Major' was an abbreviation, according to Judge Therry, of 'Major Medallion' derived from his association with the commemorative medals of 1820.

Mud-lark. See MAGPIE-LARK.

Mud-skippers or **Climbing-fish,** small marine amphibious fishes (Periophthalminae) which leave the water at low tide to move about freely upon mud-flats in search of the small crabs and insects upon which they feed. They enjoy the hot sun of the tropics, and keep themselves moist only by occasional dips in some shallow puddle. So fond are they of the freedom of the mud-flats that, if threatened with danger, they commonly skip across the surface of a stream to a neighbouring bank without submerging themselves for a moment. Their pectoral and ventral fins are modified to form arm-like limbs, which enable them to clamber over the mud and even to climb among the aerial roots of mangroves. Their eyes can be elevated upon short stalks, and see as well out of the water as in it.

The commonest species, *Periophthalmus koelreuteri,* is widely distributed throughout the tropical parts of the Indian and Pacific oceans, and reaches a length of about four inches; a larger relative grows to ten inches, and is esteemed as food by the Chinese in Queensland. See GOBIES.

A.R.McC.

Muehlenbeckia. See POLYGONACEAE.

Mueller, SIR FERDINAND JAKOB HEINRICH VON (1825-1896), was born of Danish parents at Rostock in Mecklenburg-Schwerin on 30 June 1825, educated at Schleswig and the university of Kiel (where he studied chemistry and took his Ph.D. degree in 1846), and from 1840 to 1846 carried out independent botanical researches in Schleswig-Holstein. A tubercular diathesis drove him to migrate to Australia; he reached Port Adelaide on 18 December 1847, obtained employment as a chemist, and for the next four years in his leisure time made botanical investigations in the Flinders Range, the vicinity of Lake Torrens, the Murray scrubs, Mount Lofty, and the coastal fringe at Guichen Bay. His earliest papers on the Australian flora appeared in German magazines at Adelaide. In 1852 he and Dr. Souller published a paper in a Halle journal, and he prepared one on the South Australian flora for the Linnean Society of London.

In 1852, on Sir Joseph Hooker's recommendation, he was appointed by Latrobe government botanist of Victoria, and during the next three years traversed south-eastern Australia from the mouth of the Darling to eastern Gippsland and from the Kosciusko plateau to Wilson's Promontory, doing pioneer work in the Alpine regions, ascending and naming hitherto untrodden peaks, adding materially to our knowledge of the Victorian flora, and ascertaining the suitability of various districts for settlement. In 1855 he accompanied Augustus Gregory (q.v.) as phytographic naturalist on an expedition formed with the object of tracing the Victoria River in the Northern Territory to its source. A result of the expedition was to increase the list of the flora of Australia by hundreds of new species. In 1857, in order to make the Melbourne botanical gardens more useful for economic and scientific ends, Mueller was appointed director, a position which he held until 1873; then the positions were again divided, a curator being appointed to control the gardens, while Mueller retained the position of government botanist. Under his directorship of the gardens great attention was paid to the encouragement of forestry, the acclimatization of useful plants, and the closer study of the native flora; and an economic museum, a library, and a national herbarium were established.

His botanical explorations did not end with the Victoria River expedition. In 1867 he investigated the country behind King George's Sound towards the Stirling Range, and in 1877 the vicinity of Shark Bay; he also travelled in the Tasmanian highlands. To the explorations of others he always gave practical encouragement, and greatly aided Giles, Forrest, Tietkens, Burke and Wills, and others; he raised funds for expeditions to New Guinea, and formed an Australian Antarctic committee which aided the *Antarctic* to visit South Victoria Land in 1894 (see ANTARCTICA). Among other activities he helped in 1854 to found the Royal Society of Victoria. In 1871 the King of Wurtemberg created him a hereditary baron, thus making him 'von Mueller.' For his botanical work—

and especially for his introduction of the blue gum (*Eucalyptus globulus*) into South Africa, the Mediterranean lands, and the temperate regions of South America—he received honours from France, Spain, Portugal, Italy, Austria, Denmark, Holland, Sweden, and eight German kingdoms; the Linnean Society made him a fellow in 1859, and the Royal Society in 1861. Industrious to the last, he died at Melbourne after a short illness on 10 October 1896.

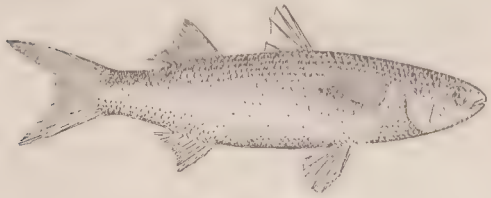
Von Mueller's written work was extraordinarily extensive. Possibly his most important work was the *Fragmenta Phytographiae Australiae* in 11 volumes, issued at intervals between 1858 and 1881. His *Plants Indigenous to the Colony of Victoria* (2 vols., 1860-5) and *Key to the System of Victorian Plants* (2 vols., 1885-7) are also of great value, and he co-operated with George Bentham in a 7-volume *Flora Australiensis* (1863-78), which depended materially on Mueller's specimens and notes. Among his other work may be noted *Select Extra-Tropical Plants* (1881), *Eucalyptographia* (1879-84), a *Systematic Census of Australian Plants* (1882-5) with its supplement of 1889, and an *Iconography of Australian Salsolaceous Plants* (1889-91). His minor contributions to botanical science are innumerable, and are scattered through the publications of learned societies all over the world. (C.M.G., 1869; K.C.M.G., 1879.) C.D.

Muir, Thomas (1765-1798), born at Glasgow on 24 August 1765, was the son of a prosperous tradesman who in 1753 published a pamphlet on English trade with foreign countries. He was educated at the grammar school and the university of Glasgow (M.A., 1782), where he read law after graduating, but was expelled in 1784 for lampooning professors. In 1787 he betook himself to Edinburgh, where he was admitted to the faculty of advocates: he also became an elder of the church at Cadder near Glasgow, and sat in the general assembly. Interesting himself in the advocacy of parliamentary reform, he in 1792 helped to found in Glasgow a branch of the London 'Friends of the People,' and at one meeting read a communication from the United Irishmen. The British government, scared by the outbreak of the French Revolution, was inclined to take the mildest suggestion for parliamentary reform as a threat of a similar outbreak in Britain; Muir was arrested on 2 January 1793 on a charge of sedition, liberated on bail, and outlawed because he did not return from a visit to Paris by the day set for his trial (though he was on his way back). On 31 August 1793 he was sentenced to transportation for 14 years—it is alleged, probably with truth, that the jury was packed and the presiding judge (the notorious Lord Braxfield) bitterly antagonistic. A fortnight later Thomas Fyshe Palmer (q.v.) was condemned on a similar charge and given a seven years' sentence, and thenceforth they were companions in misfortune. At the end of November they were sent by sea from Edinburgh to London, and at first put in irons and set to the same work as the worst convicts; but a warning came from Edinburgh that, if persons like Muir and Palmer were treated as felons, Scottish juries would refuse to convict in treason cases. In January 1794, therefore, they were un-ironed, segregated from the mass of convicts, and allowed to see their friends. In February they, along with Maurice Margarot and William Skirving (who had been convicted of the same offence, sedition), were placed aboard the transport *Surprize*; a fifth convict, Joseph Gerrald, was embarked in the *Sovereign*, which followed the *Surprize* to Australia at a short interval, and the five became widely known as the 'Scottish Martyrs.' Margarot's wife was allowed to travel with her husband. The *Surprize* sailed on 2 May and reached Port Jackson on 25 October. During the voyage Palmer and Skirving were accused of having fostered, if not devised, a serious mutiny, and were placed under close arrest; Muir, who had been very ill, was not considered an accomplice, and Margarot was taken into favour as an informer. Margarot, indeed, was according to Muir 'rejected and expelled from our society' as soon as the Martyrs reached New South Wales. The charges against Palmer and Skirving were not substantiated, and Grose assured them that they would receive every possible indulgence so long as they kept clear of politics; as for Muir, he could not speak too highly of his treatment—'gratitude will for ever bind me to the officers, civil and military.' Grose had already been instructed from London that the Scottish transportees must not be assigned compulsorily to any service, though, unless they performed such work as Grose offered them, they could not claim rations from the government; Hunter a year later stated that they had been 'particularly cautious' to claim nothing of the kind. Muir, Palmer and Skirving were allotted neighbouring houses on the eastern bank of the Tank Stream, and Muir bought a farm on the slopes of what is now Gore Hill; he named it 'Hunter's Hill,' after his father's home in Scotland, but the name has since been transferred to a peninsula south of it across the Lane Cove River. Considering himself a free man within the settlement, Muir busied himself with the amelioration of the convicts' lot, and conducted the first Presbyterian services held in New South Wales. Hunter, when he arrived in 1795, described Muir as 'a sensible, modest young man, of a very retired turn;' Skirving was 'sensible and well-informed,' Palmer by no means turbulent and restless (as he had been described), and Margarot talkative and a grumbler. Within a week of meeting them Hunter had conceived scruples about his power to detain them in the settlement. He inclined to the acceptance of their representations that their sentences contemplated only (*a*) transportation and (*b*) interdiction from a return to Britain, and suggested to the authorities in London that they might be allowed to return to Ireland. The suggestion was sternly rejected. In June 1797 he was told that it was his duty 'to detain those persons within your Government until the terms of their respective sentences are compleated.' Meanwhile, however, an American brig, the *Otter*, visited Port Jackson at the beginning of 1796, and Muir on 11 February went clandestinely aboard her and escaped; it was believed that her visit was designed for his rescue. She took him to Nootka Sound in Alaska (an unusual port for a vessel primarily intended to rescue a prisoner), whence he worked his way down the American coast to Panama, crossed the isthmus, and shipped aboard a Spanish frigate to Cuba; the governor there detained him as a suspect republican and sent him to Cadiz, but on the way the frigate was captured by two British men-of-war, and Muir in the fight was severely wounded in the face. He was put ashore in Spain with the other wounded, and at the request of the French Directory was released by the Spanish government and allowed to go to France. But his wound proved incurable, and he died at Chantilly near Paris on 27 September 1798.

The remaining martyrs may be conveniently dealt with here, except Thomas Palmer, who is separately treated. Gerrald, who had been ill ever since his conviction, bought a small house at Farm Cove; Hunter gave him every possible privilege, but he died of phthisis on 16 March 1796. Skirving bought a farm near Muir's, overworked himself at the first harvesting, and died of dysentery on 19 March 1796. Margarot, a far less educated and refined man, served out his sentence in the colony. In 1804 Governor King, suspecting that he was mixed up in the abortive revolt of that year (see IRISH EXILES), had his house searched, and discovered 'some very elegant Republican Sentiments, and general infamous Abuse of every person in the Colony, from the period he landed.' To prevent himself from being sent to the coal-mines, Margarot then declared that he was employed by high authorities in England to send secret reports on King's conduct; and the governor, half-believing it, 'directed him to be supplied with pens, ink and paper.' In 1805, however, his conduct became unbearable, and King exiled him to Tasmania, where he exasperated Colonel Collins into vehement denunciations. In 1807 his sentence expired and he returned to England, where he died in poverty on 11 November 1815.

Mulga. See ACACIA.

Mullet, Gray, members of the family Mugilidae; about two dozen species are known from Australia, nearly all valuable as food-fishes. They are chiefly marine in habit, but may enter fresh water periodically, and one, the Pink-eye Mullet (*Trachystoma petardi*), is restricted to the fresh water of the eastern rivers of New South Wales. The so-called Sea Mullet (*Mugil cephalus*) is one of the most important fish marketed in New South Wales; it occurs in enormous quantities in inlets, as



Sea Mullet.

well as on the open coast, is captured by net-fishermen in greater or less abundance throughout the year, and occasionally attains a length of 30 inches. When migrating northwards (about April or May), its shoals hug the coast-line, often swimming among the breakers; this makes it impossible to use a drift-net for their capture. This species ranges over the temperate seas of the world, and is known by various names in the several Australian States, being called 'sand mullet' in Victoria and Tasmania and 'mangrove mullet' in Queensland. The Sand Mullet or Tallegalane (*Myxus elongatus*) of New South Wales is less valuable as a food-fish, although at times plentiful in the markets. Other allied species are the Flat-tailed or Fan-tailed Mullet (*Mugil argenteus*), the Diamond-scale Mullet (*M. waigiensis*), the Silver Mullet (*M. georgii*), and a number of less-known species, each of which has various vernacular names. In all members of the family the teeth are either minute or wanting, and the peculiarly-formed mouth is especially adapted for engulfing the microscopic organisms which supply them with food. For red mullet see GOAT-FISH.

A.R.McC.

Mundy, GODFREY CHARLES, joined the army in 1821 (lieutenant, 1823; captain, 1826; major, 1839; lieutenant-colonel, 1845; colonel, 1854), and served at the siege of Bhurtpore (Bharatpur) in 1825-6 as aide-de-camp to Lord Combermere. In 1832 he published *Pen and Pencil Sketches: the Journal of a Tour in India* (3rd edn., 1858). On 25 June 1846 he arrived in Sydney as deputy-adjutant-general of the military establishment, and remained there until 25 August 1851. During these five years he employed his leisure in writing amusing sketches of colonial society in New South Wales, Victoria, Tasmania, and New Zealand; these were published in 1852 under the title *Our Antipodes* (2nd edn., 1852; 3rd edn., 1854; 4th edn., 1857). In 1857 he was appointed lieutenant-governor of Jersey, an office which he held until his death on 10 July 1860.

Munro, JAMES (1832-1908), born in Sutherlandshire, Scotland, on 7 January 1832, at the age of 16 entered the employ of Constable and Co., printers, Edinburgh. Migrating to Melbourne in 1858, he continued to work at his trade for six years, but in 1865 founded a building society which became the largest in Victoria, and between that date and 1887 founded and directed a woollen mill, an insurance company and two banks. Entering local politics in 1874, he attached himself to Graham Berry (q.v.), was minister of public instruction in that leader's short-lived cabinet of 1875, stood aside from the intrigues which occupied the next ten years, and became prominent again as leader of the opposition to the Gillies-Deakin coalition of 1886. In 1890 he visited England and procured a large amount of British capital for his various companies; on the strength of his consequent reputation as a successful financier he ousted Gillies (whose financial policy was collapsing) and formed a cabinet chiefly remarkable for the inclusion of William Shiels and George Turner. As premier he was a member of the federal convention of 1891, but took no great part in the debates. In February 1892 Munro, gladly extricating himself from the disastrous crisis of 1891-3, succeeded Graham Berry as agent-general for his colony; but among the worst failures of those years were his two banks, and one of the first acts of the Patterson ministry of 1893 was to recall him and replace him by Duncan Gillies. After his return to Victoria he took no further part in politics, and died at Melbourne, on 25 February 1908.

Murdoch, WILLIAM LLOYD (1855-1911), born at Sandhurst—now Bendigo—in Victoria on 18 October 1855, a solicitor by profession, was the most graceful and accomplished Australian batsman of the eighties and in 1882-4 ranked second only to W. G. Grace among the batsmen of the world. His first appearance in test cricket was made at Melbourne in April 1877 against Lillywhite's eleven; he went to England in D. W. Gregory's team of 1878—which got an M.C.C. team out for 19 runs (see CRICKET)—mainly on the strength of his wicket-keeping; and he was a member of the team that defeated Lord Harris's eleven at Melbourne in January 1879. Up to that time his batting had not been brilliant, but then he suddenly developed into a great batsman, captained the next three Australian teams in England

(1880, 1882, 1884), and distinguished himself equally in both capacities. His score of 211 in the test match of August 1884 still ranks as the highest but one made in test cricket, being excelled only by R. E. Foster's 287 in December 1903. At the end of 1884 he retired from big cricket, but returned to it in 1890 to captain the Australian team of that year in England. From 1891 onwards he lived in England, captaining the Sussex team on several occasions and playing for London County under the leadership of W. G. Grace. As late as 1904, when he was 49 years old, he scored 140 for Gentlemen against Players. Outside test cricket he played, while in Australia, for New South Wales, scoring 321 in an intercolonial match in 1882. On 18 February 1911, during a visit to Australia, he died of apoplexy while watching a match between Australia and South Africa on the Melbourne cricket-ground. In test matches he scored 896 runs, an average of 32; in first-class cricket (including tests) 17,319 runs, an average of 26.64.

J.C.D.

Murphy, Francis (1795-1858), born at Navan in Ireland on 20 May 1795, educated at the diocesan seminary and St. Patrick's College, Maynooth, and ordained priest in 1826, after 11 years of work in Bradford and Liverpool met Dr. Ullathorne—who described him as 'a priest of six-priest power'—and aided him in obtaining young priests for the diocese of Sydney. Reaching Sydney with them on 15 July 1838, he was given work in the city by Bishop Polding, and in 1840 succeeded Dr. Ullathorne as vicar general, administering the diocese during Bishop Polding's absence in Europe. On 8 September 1844 he was consecrated first bishop of Adelaide, where at the moment there was 'neither church nor school nor government aid of any kind whatsoever' for Catholics; but soon after his arrival there an English convert to Catholicism, William Leigh, gave the diocese £2000, 500 acres of land in the colony, and a further 4 acres in Adelaide as the site of a cathedral. This cathedral Dr. Murphy began to build when the wealth of the Victorian goldfields was found to be flowing across the border in return for South Australian wheat; but the earlier struggles had debilitated him and he died of phthisis on 26 April 1858.

E.M.O'B.

Murphy, Sir Francis (1809-1891), born at Cork in Ireland and educated at Trinity College, Dublin and the Royal College of Surgeons in London (M.R.C.S., 1835), migrated to Sydney in June 1836 and was made district surgeon for Bungonia near Goulburn on 1 January 1837. He soon relinquished his profession for the more congenial life of a farmer and squatter, growing wheat in the Goulburn district in the early forties and leasing for a sheep-station 50,000 acres at Tarrawingee near Beechworth in 1844. When Victoria in 1851 became a separate colony, Murphy entered the council as member for the Murray and was made chairman of committees; he gave up the management of his station (which he sold in 1857) and thenceforth resided in Melbourne. When in 1856 responsible government was initiated, he was returned by the Murray electorate to the new assembly, and was chosen as speaker—having given an undertaking, which the other candidate refused to give, that he would take no active part in any debates; he represented the Murray until 1866, and then became member for Grenville, and held the speakership continuously until 1871, when he failed to secure re-election to parliament. From 1872 to 1876 he sat in the council as a member for the Eastern province, but took no active part in politics. Retiring into private life in 1877, he died at Melbourne on 30 March 1891.

Murphy's services to his colony were considerable. In the council of 1851-6 he carried important pastoral legislation, and combined with his political duties those of chairman of the central road board, taking also a useful part in the debates on the new constitution. As speaker of the assembly he was, of course, debarred from political work, but his moderating influence was conspicuous during the long quarrel between the two houses in 1864-8. He was a member of the commission on the Burke and Wills expedition of 1863; also a member of the council of the university from 1853 until the end of 1878. (Kt.Bach., 1861.)

Murray, George Gilbert Aime, third son of Sir Terence Aubrey Murray (q.v.), was born in Sydney in 1866, left Australia at the age of 11, and was educated at Merchant Taylors' school, London, and St. John's College, Oxford (M.A., 1904, and D.Litt. Oxford, 1910; LL.D., Glasgow, 1900; LL.D., Birmingham, 1909). He was elected fellow of New College, Oxford, in 1888, was appointed professor of Greek at the university of Glasgow in 1889, and held that post for 10 years. After an interval of eight or nine years, during which he wrote two actable plays (*Carlyon Sahib* and *Andromache*), produced critical work upon Euripides, and translated a number of that author's tragedies into English verse, he was appointed (1908) regius professor of Greek in the university of Oxford. Since that time he has translated plays of other Greek dramatists, and has written books, essays, and addresses on many subjects, ancient and modern. Gilbert Murray is a brilliant example of the newer order of classical scholar, who can take a lively practical interest in current questions and business while assiduously prosecuting his special studies. In his endeavour to bring the classics 'down from the clouds' he has produced versions which enjoy a wide popularity, although competent critics mostly agree that his method is apt to clothe his originals in a somewhat false atmosphere of modernity; his versions have been styled 'a muriate of Euripides.' His other writings are original in thought and bright in style. He was made trustee of the British Museum in 1914, has been chairman of the League of Nations Union since 1923, and is a fellow of the British Academy and of the Royal Society of Literature. Apart from his translations his chief writings have been *The Rise of the Greek Epic* (1907), *Five Stages of Greek Religion* (1913), *Stoic Philosophy* (1915), *Faith, War, and Policy* (1918); *Collected Essays and Addresses* (1922).

Murray, Harry William, born at Launceston in Tasmania on 1 December 1884, was the best-known fighting soldier of the A.I.F. Murray, who had served in the Australian field artillery for some years and had worked on the mining-fields, landed on Gallipoli as a private in the machine-gun section of the 16th battalion in which Lance-corporal—afterwards Major—Percy Black, also a miner and a famous fighter, was his immediate senior. After fighting Turks in both front and rear at the landing on Gallipoli, for which he received the D.C.M., Murray was promoted, and, as an officer of the 13th battalion in France, conducted a brave but unsuccessful advance near Mouquet Farm

during the Somme battle of 1916. The gallantry and skill with which he extricated his company brought him the D.S.O. For his leading of the 13th, and 'for most conspicuous bravery,' in an attack at Stormy Trench during the following winter he was awarded the Victoria Cross; and for his gallantry in the first battle of Bullecourt in April 1917 he was given a bar to his D.S.O. He rose through the various ranks (sergeant, 1915; 2nd lieutenant, 1915; lieutenant, 1916; major, 1917; lieutenant-colonel, 1918), and subsequently commanded the 4th machine-gun battalion. (C.M.G., 1919.) C.E.W.B.

Murray, JOHN. See EXPLORATION BY SEA.

Murray, SIR JOHN HUBERT PLUNKETT, the second son of Sir Terence Aubrey Murray (q.v.), was born at Sydney on 29 December 1861 and educated at the Sydney Grammar School, University College, London, and Magdalen College, Oxford (B.A., 1886), and also studied at Berlin. While at Oxford he won the heavy-weight amateur boxing championship of England, and distinguished himself as an oarsman and swordsman. In 1886 he was called to the bar at the Inner Temple, and returned to Australia to practise. In 1901 and 1902 he acted as a district court judge. As a volunteer he joined the first New South Wales regiment of infantry, and afterwards transferred to the New South Wales Irish Rifles, which he commanded in 1898. During 1900-1 he served in the South African war, and in recognition of his services was in 1902 awarded the rank of major in the British army. In 1904 he retired from military life with the rank of lieutenant-colonel, and was appointed chief judicial officer of British New Guinea, becoming as such a member of its executive and legislative councils. In April 1907, British New Guinea having in September 1906 become a territory of the Commonwealth under the name of Papua, he was made acting administrator, and in 1908 was promoted to the lieutenant-governorship, which position he still (1926) holds. In 1919 he was chairman of a royal commission on the Mandated Territory of New Guinea, and delivered a minority report suggesting the amalgamation of that territory with Papua.

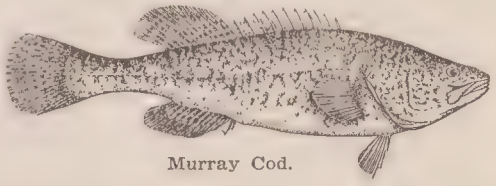
In developing the policy of Sir William MacGregor (q.v.) Murray at first incurred the resentment of many white planters, who considered that their interests and the economic progress of the territory were being unduly sacrificed to those of unmanageable and ungrateful natives; this resentment, however, has died away, and it has been found possible to extend the area of plantation and foster white enterprise without in any way neglecting or diminishing the welfare of the native tribes. In 1912 Murray published *Papua; or British New Guinea from 1907 to 1920,* and in 1925 *Papua of To-day.* His annual *Reports* are valuable storehouses of ethnological and historical information. (C.M.G., 1914; K.C.M.G., 1925.) See PAPUA. L.A.

Murray, SIR TERENCE AUBREY (1810-1873), born at Limerick in Ireland in 1810 and educated at Dublin, was son of a Terence Murray who was paymaster of the 48th regiment, and served with it in New South Wales from 1817 to 1824. Soon after the regiment was transferred to Madras, Murray disposed of his commission, returned to Ireland, and in 1827 fetched his son to Australia to take up farming there. Terence spent four years on his father's estate at Taradale near Lake George, and then—having been made a magistrate by Bourke—guided the mounted police in a campaign against bush-rangers in the Murrumbidgee and Monaro districts. Towards the end of the thirties he took up Jingellic station on the upper Murray and occupied the land across the river afterwards known as Jingellic South. In June 1843 he entered politics as member of council for Murray, King and Georgiana counties; this seat he held till 1851, when he became member for the Southern Boroughs (Goulburn, Queanbeyan, Braidwood, and Yass). The same constituency returned him to the new assembly from 1856 to 1859, and he represented Argyle from 1859 to October 1862. He was then nominated to the legislative council, and retained the position till his death on 22 June 1873.

Murray's parliamentary career was not marked by any special legislative achievement, but was useful in another direction. He was secretary for lands and works in the first (1856) and second (1857-9) Cowper ministries, but resigned in January 1858 to make room for John Robertson. On 31 January 1860 he was unanimously chosen to succeed Sir Daniel Cooper as speaker of the assembly, and only left the chair on 14 October 1862 to succeed W. C. Wentworth as president of the legislative council. For such posts, requiring in their holder dignity, equability, and impartiality, Murray was well fitted, and his tenure of them advantaged both the houses and the colony. (Kt. Bach., 1869.)

Murraya, a small genus of the family Rutaceae, consisting of trees or shrubs, chiefly tropical. The calyx is 5-cleft; petals 5, narrow; stamens 10, free; fruit a 2-seeded berry. *M. exotica* (China Box), found in north-eastern Queensland, has very fragrant white flowers, and is commonly cultivated in gardens. The wood is light-yellow and close-grained, but apt to crack; it has been tried for wood-engraving (for which there is now little demand), and is used for the handles of implements. Suggestions have been made for the extraction of a perfume from the flowers.

Murray Cod (*Oligorus macquariensis*), the most valuable freshwater fish of the southern half of Australia; it inhabits the whole Murray River system and the head-waters of some coastal streams of New South Wales and southern Queensland. Attempts to transfer it to the Yarra system in Victoria failed, but it was



Murray Cod.

successfully colonized in Lake George,. and throve there until the lake practically disappeared through evaporation. It attains a length of six feet and a weight of 150 pounds. It is an excellent food-fish, and a considerable number of inland fishermen are engaged in its capture, forwarding their catch to the markets of Sydney, Melbourne, and Adelaide. A.R.McC.

Murrells, JAMES. See WILD WHITE MEN.

Muscovite. See MINERALOGY.

Museums. Each of the six states has in its capital city a museum, an art gallery, and

a public library. These are often housed in the one building, so that any description of the museums must to some extent overlap the articles on ART GALLERIES and LIBRARIES, which should be consulted. Outside the capital cities there are many small collections of the museum type (see MACLEAY, ALEXANDER and MACLEAY, WILLIAM).

The Australian Museum.—In a despatch dated 30 March 1827 Governor Darling was informed that the colonial office sanctioned an expenditure of £200 a year on the establishment of a museum in Sydney, and that W. Holmes had been appointed zoologist. During the first two decades of the museum's life it had no regular abode, but was housed at first (1830) in the judge-advocate's office—where the lands office now stands. Thence it was moved to the legislative council chambers, and in 1836, owing to the growth of the collection, shifted again to Judge Forbes's house at the corner of Bridge- and Gresham-street; at this time, according to its first catalogue (1837) it included 800 exhibits. In 1840 it was transferred to the surveyor-general's office opposite the mint; about 1842 it was placed in the Darlinghurst courthouse. The original name of this migratory museum was 'The Colonial Museum,' but in 1834 it was given its present name.

Darling in 1831 reserved an allotment in Hyde Park for a building to be put up by the Australian Subscription Library—a private society, which obtained this concession on condition that rooms in the building should be set aside for the colonial museum. In 1835, however, Bourke reversed the arrangement, and proposed to erect in connection with the botanic gardens a museum in which accommodation might be given to the society's library; in April 1836 the colonial office sanctioned the expenditure of £4000 on such a building. In June of that year occurred the first recorded meeting of the 'General Committee of the Australian Museum and Botanical Gardens'—a body consisting of Alexander and George Macleay, Phillip Parker King, John Vaughan Thompson (deputy-inspector-general of hospitals), Edward Deas Thomson, Charles Sturt (the explorer), John Jamison, William Macarthur, George Porter, and R. A. Wauch, the first six forming the museum sub-committee. Nothing, however, was done about the building until 1845, when Charles Nicholson (q.v.) persuaded the legislature to authorize a commencement of the building opposite Hyde Park in which the museum is now housed. Part of the existing north wing was completed in 1849, and the collections were transferred to it from the court-house. It was also used by local societies for their meetings, and in 1854 for the display of specimens collected for the Paris exhibition of agriculture and industry of 1855. The west wing of the building was begun in 1861; in 1892 an upper story was placed on the north wing; in 1897 the south wing was begun, and was enlarged in 1909.

The system of administration—by a curator acting under a managing committee—was altered in 1854, when a board of trustees was substituted for the committee. Originally this board consisted of 12 members holding official positions, who, when they left office, vacated the trusteeship in favour of their respective successors; 12 nominees holding the position for life, whose successors would be co-opted by the board; and one appointed by the governor-in-council. In 1902 five more official trustees were added. The list of actual custodians of the exhibits, with their titles, is as follows:—

1828-30. William Holmes, colonial zoologist.
1836. George Bennett, zoologist, curator, and director (these titles seem to have been used indiscriminately).
1841. William Branwhite Clarke, curator.
1842. William Sheridan Wall, curator.
1850. Simon Rood Pittard, curator.
1861. Johann Ludwig Gerhard Krefft, curator.
1874. Edward Pierson Ramsay, curator.
1895. Robert Etheridge, junior, curator (1917, director and curator).
1920. Charles Hedley, acting-curator.
1921. Charles Anderson, director.

Prominent among the museum's contents are the Hargraves collection of shells presented by Thomas Walker; Day's types of Indian fishes; the Waterhouse collection of Lepidoptera presented by G. A. Waterhouse; the Roth collection of Queensland ethnography; the Stockdale collection of aboriginal weapons and implements presented by William Dixson, and the Grant ornithological collection. Besides these collections, which are of the 'study' type, the museum galleries display fine collections in all departments of natural history except botany, which is treated by the national herbarium attached to the botanic gardens (q.v.). Among the exhibits are the journal of Cook's first voyage, known as the 'Batavian' copy, presented by F. H. Dangar, two Egyptian mummy-cases presented by Sir Robert Lucas-Tooth, a group of aboriginal figures modelled from life by T. Rayner Hoff (the gift of E. Wunderlich), and numerous habitat groups. The ethnology of the Pacific is illustrated by one of the most complete collections extant. The publications issued are extensive, the principal being the *Records*, a serial established in 1890 and still being issued; other scientific publications include memoirs, catalogues, special catalogues, and monographs. Besides these a non-technical quarterly, *The Australian Museum Magazine*, first issued in 1921, is published with the object of bringing the museum into closer relationship with the lay public.

The *Technological Museum* at Sydney originated as a collection of industrial exhibits in the Sydney exhibition of 1881 (see EXHIBITIONS), but this, with the ethnological series amassed by Edward Pierson Ramsay (q.v.), was destroyed by the fire of 1882. Ramsay energetically set about replacing his lost specimens, and the technologic collection was thereafter temporarily housed in the Agricultural Hall, Outer Domain, until it was transferred to Ultimo (an outlying ward of Sydney). The first managing committee, which consisted of Sir Alfred Roberts, Professor Liversidge, and Robert Hunt, planned a museum of a purely industrial nature on the lines of the Victoria and Albert Museum in South Kensington, London, and this was opened on 4 August 1893. Its objects are (*a*) to assist the development of the State's natural resources by exhibiting collections of its raw products, investigating their economic possibilities, and publishing results for the benefit of manufacturers and traders, (b) to exhibit, both for comparison and for general information, economic products of the world at large, gathering and disseminating all available information about them. Research is particularly encouraged, and during the last 30 years more than 250 original studies of relevant subjects have been published. The exhibits connected with building stones, timbers, essential oils and kinos, and the porcelain in-

dustry, are especially valuable, and the collection that illustrates the development of the wool industry in Australia contains specimens put aside in 1804 by Samuel Marsden.

The *National Museum* at Melbourne originated in a collection illustrating Victorian natural history and geology made under the direction of Captain Andrew Clarke (q.v.); these were removed to the university building in 1856, and Professor Frederick McCoy was appointed director in 1858. In 1862 the collection was removed to a 'National Museum' built in the university grounds, and in 1870 was placed under the control of the library trustees, who thus became 'Trustees of the Public Library, Museums, and National Gallery.' McCoy was director till his death in May 1899; Professor Baldwin Spencer succeeded him, and at the end of the year the collections were moved to a building in the public library, which was formally opened on 19 December. In 1906 the central block of the existing Russell-street museum was opened. Among notable exhibits are many mammals secured for the museum by John Gould and J. E. Gray, and three examples of gorillas collected by Du Chaillu; the H. L. White collection of Australian birds' skins, the Campbell collection of Australian eggs; a large number of fishes from the Godeffroy and Bleeker collections; the Curtis collection of British insects (15,780 specimens) together with Curtis's types, notebooks, etc. secured in 1864; and the Howitt (44,800 specimens) and Castelnau collections of insects. Palaeontology is illustrated by the Bean collection of plants from the upper Jurassic of Scarborough; the Lycett collection of Oolitic fossils (3100 specimens); the Wright collection of Jurassic forms (2000 specimens); and the Krantz collection, numbering 20,000 examples. The Australian geological collections are strong in Tertiary fossils, and include those made by MacGillivray, Dennant, and Creswell. The Hall graptolite series for Victoria contains 1500 type-fossils. The Australian ethnological collection is especially strong in sacred and ceremonial objects, and contains most of those figured by Brough Smyth, and all those figured by Spencer and Gillen, together with their negatives and kinematographic and phonographic records illustrating all phases of native life. The stone implement collection contains over 20,000 specimens.

The *Industrial and Technological Museum*, Melbourne, was established in 1870, under the control of the trustees of the public library. The collections were housed at first in a building which had been erected in the library grounds for the exhibition of 1866, and the mining and other models which had been exhibited at the national museum were transferred to it. In 1893 a special hall was erected in the same grounds, and the collections were shown in it till in 1899 it was needed to accommodate the natural history section of the national museum. The exhibits were then stored until, on the completion of the new library building, the Queen's hall (the old reading-room) could be utilized as their temporary home. Here they were thrown open to the public in 1915.

The *South Australian Museum* at Adelaide was first opened in the building of the South Australian Institute in 1862; its contents were chiefly local minerals and fossils. In 1884 the west wing of the public library was completed, and the northern half of the building was set apart for the museum. A separate building for the natural history museum was opened in 1895, and the eastern wing of the public library block, opened in 1915, is now used principally as an extension of the natural history museum. The Australian ethnological collection is perhaps unexcelled in the world, and the mineralogical collection is also exceptionally good. The exhibit of more than 400 skulls of Australian aborigines is of interest to anthropologists the world over. The museum possesses an almost complete skeleton of *Diprotodon australis*, plaster casts of which have been sold to some of the principal museums of Europe and America. A large deposit of bones, discovered in 1892 at Lake Callabonna (about 150 miles east of Hergott), contained not only bones of *Diprotodon*, but also remains of a large extinct struthious bird (*Genyornis newtoni*), of the giant wombat (*Phascolomys gigas*), and of several species of extinct kangaroos.

Since its inception the museum has been in charge of the following officials:—

1862. F. L. Waterhouse, curator.
1882. William Haacke, curator.
1889. Edward Charles Stirling, honorary director.
1894. E. C. Stirling, director.
1913. Edgar Ravenswood Waite, director.

A bequest of £16,000 from the Morgan Thomas estate affords funds for the purchase of collections, the despatch of expeditions to the interior, and (since May 1918) the publication of *Records of the South Austra'ian Museum*. For further notes on the founding of the museum see *Transactions* of the Royal Society of South Australia vol. i (1877).

The *Queensland Museum* at Brisbane originated in the enthusiasm of certain local naturalists, among whom was Charles Coxen, a relative of the ornithologist John Gould. In 1855 the collections were housed in the so-called 'observatory' building on Wickham-terrace, but were afterwards removed to the old parliament-house and then to the old post-office building in Queen-street. In 1876 a board of trustees was appointed, with A. C. Gregory as chairman, and the name 'Queensland Museum' was officially given to the institution. In 1879 it had grown beyond its accommodation and was moved for the fourth time, to occupy what is now the public library in William-street, William A. Haswell being at the same time appointed curator. With the addition of the Sir William Macgregor ethnological collection from Papua the museum again became overcrowded and in 1900 was removed to the exhibition building in Bowen Park, where it is still housed. The two floors of the large hall (214 ft. x 86 ft.) are mainly devoted to natural history and ethnology. There is an exceptionally fine collection of vertebrate fossils, and many water-colour pictures by Ellis Rowan illustrating the flora of the State are on exhibition. Between 1891 and 1911 ten volumes of *Annals* were published; since 1911 eight volumes of *Memoirs of the Queensland Museum* have appeared. The officers in charge of the museum have been:—

1855. Charles Coxen, secretary and curator.
1873. Karl T. Staiger, custodian.
1879. William A. Haswell, curator.
1881. Frederick Manson Bailey, acting-curator.
1882. Charles W. de Vis, curator.
1905. Charles James Wild, acting-curator.
1911. Ronald Hamlyn Harris, director.
1917. Heber A. Longman, director.

The *Western Australian Museum* originated as a geological museum which C. G. Nicolay founded in order to house collections made by Frank Gregory and others. In 1889 it was transferred from the old guard-room at Fremantle, where Nicolay had placed it, to the office of the government geologist in Perth, a collection

made by B. H. Woodward was added, and Woodward himself was made curator in 1891. In 1892 the collections of the Swan River Mechanics' Institute were taken over, and the museum was thenceforth known as the Perth Museum. In 1895 it was transferred from the control of the department of lands to the care of a committee of which Sir James Lee Steere was chairman, and new buildings were commenced; in 1897 the name 'Western Australian Museum' was formally adopted, and an art gallery was added. In 1911 by the passing of an act it became incorporated with the public library as part of the 'Public Library, Museum, and Art Gallery of Western Australia.'

The first museum in Tasmania was the *Franklin Museum*, founded in 1842 by Sir John and Lady Franklin: the building was placed on a 10-acre block in Kangaroo valley, three miles north of Hobart. The museum was supported out of Lady Franklin's Ancanthe estate, the revenues of which were otherwise devoted to educational purposes. Sir John Franklin entrusted it to the care of the Tasmanian Society (see SOCIETIES, LEARNED), choosing its trustees from that body and giving the members special privileges. When the Tasmanian Society was absorbed by the Royal Society of Tasmania, the museum seems to have fallen into disrepair; in 1853 its cases and fittings were bought by the Royal Society for its own museum, its library was dispersed, and its collections (of which no details are known) probably went along with the fittings. Its first and only committee of management comprised Bishop Nixon, J. E. Bicheno, the colonial secretary, J. P. Gell, Ronald Gunn, and T. J. Ewing. The building is still in existence, but is unused.

In 1843 was founded the Royal Society of Tasmania, the formation of a museum and library being one of its avowed objects. Mention is made of a museum in the report for 1844, and in that for 1845 it was proposed to locate exhibits in the secretary's cottage in the government domain. From 1848 to 1852 they were housed in a committee-room of the legislative building, and in 1852 were moved to leased premises in Harrington-street. After prolonged negotiations with the government, during which four sites were offered and withdrawn, the society obtained in 1860 a site at the corner of Argyle- and Macquarie-street, on which the nucleus of the present building was at once erected; it was opened as *The Royal Society's Museum* on 29 January 1863. In 1885 important alterations were made: the museum (along with the botanical gardens) was handed over by the society to a board of trustees appointed by the government, its name was changed to *The Tasmanian Museum*, and in 1886 the building was enlarged, as it was again in 1901. The custodians of the museum since its establishment in Harrington-street have been:—

1862. Thomas Robin, curator.
1883. Alexander Morton, curator.
1908. Robert Hall, curator.
1912. T. Thompson Flynn, honorary curator.
1913. G. H. Hurlstone Hardy, assistant-curator.
1918. Clive Lord, assistant-curator.
1920. Clive Lord, curator.
1923. Clive Lord, director.

Musgrave, SIR ANTHONY (1828-1888), born in 1828 at Antigua in the West Indies, and educated at the local grammar school, was in 1850-1 private secretary to the governor of the Leeward Islands, in 1851 entered as a law student in the Inner Temple (but was never called to the bar), in 1852 was appointed treasury accountant of Antigua, and became colonial secretary there in February 1854. In 1860 he was promoted administrator of Nevis (one of the Leeward Islands), and in April 1861 was transferred to administer St. Vincent, becoming its lieutenant-governor in May 1862. From April 1864 to June 1869 he was governor of Newfoundland, in June was appointed governor of British Columbia, held the post till 1871 (when British Columbia was absorbed in the Dominion of Canada), and from May 1872 to June 1873 was lieutenant-governor of Natal. He was then appointed governor of South Australia, taking up office on 9 June 1873. Many important measures were passed during his rule, including the measures initiated by James Boucaut (q.v.), which enabled the government to borrow largely for the development of the colony's resources. On 29 January 1877 he left the colony, and from 1877 to 1883 was captain-general and governor-in-chief of Jamaica. In 1883 he returned to Australia as governor of Queensland, taking office on 6 November. He died at Brisbane on 8 October 1888, from an attack of apoplexy. (C.M.G., 1871; K.C.M.G., 1875.)

Music is a department of artistic activity in which Australia has shown a peculiar interest and bids fair to take at least its full place in the world. Whether the reason be the climate and the livelier and more expansive temperament encouraged by it, or merely the social conditions, the fact itself can hardly be denied that the Australians are a 'musical people.' Whether in the formation and progress of their own musical societies and orchestras, or in the crowded welcomes offered to visiting artistes and choirs, they display a zest which contains nothing of the factitious. Such visitors, including the greatest, have frequently attested their appreciation of this substantial recognition by repeating their visits, in spite of the distance to be travelled and the loss of time incurred. The placing of great, and even sumptuous, organs in town halls, and the provision of recitals (gratis) for citizens, are another indication of the same spirit. Whatever else the climate may do, it certainly tends to produce vocalists, and native-born singers—to name here only Dame Nellie Melba and Ada Crossley—have won an international distinction. Though the country is still too young to have produced composers of great note, there is much promise in this respect also, and it may be anticipated that Percy Grainger (for example) is but a forerunner of a list of musical creators. Meanwhile education in music is assiduously cultivated, from the state schools upwards. Apart from plenteous private instruction, Australia has two university chairs of music (Melbourne and Adelaide), and three conservatoria of a public character (Sydney, Melbourne, and Adelaide). Musical examinations and competitions are also established throughout the Commonwealth. The musical criticism of the press is competent and keen, and almost invariably frank and discriminating.

Musical Development.—The history of musical development in the several States has naturally been much the same, and it is scarcely possible to treat of one apart from the rest. The prominent practitioners of Australia have at all times travelled to and fro, and the visiting celebrities have made no other distinction than that of naturally choosing the greater centres of population. Necessarily, however, New South Wales secured a considerable start of the rest since the day when Surgeon Worgan of H.M.S. *Sirius* landed his piano on the shore of Port Jackson in 1788. It was, for example, not till 1836 that a similar

instrument was floated ashore through the surf of Holdfast Bay, South Australia, by Mrs. Hindmarsh, wife of the first governor. In that same year Vincent Wallace (q.v.) was already giving in Sydney a concert at which he produced his own compositions for violin and piano; his opera, *Maritana*, which he subsequently produced in London, is said to have been partly composed in Australia. Meanwhile in Hobart were the Deane family, whose head had been a player in the London Philharmonic Society. These came to Sydney in the same year (1836) and gave that city its first classical string quartet concerts. Two more generations of this gifted family were settled in Sydney; one of its members, Arthur Deane, became a leading baritone with the Carl Rosa company in England in the nineties. Vincent Wallace's sister, Mrs. Wallace Bushelle, after appearing in England in her brother's opera, returned to Sydney in 1864 and settled there as a teacher. Meanwhile in 1841 there had arrived the erudite Isaac Nathan (q.v.), who inaugurated oratorio in Australia at a sacred concert in St. Mary's Cathedral. Nathan has been called the 'father of music in Australia,' and for 23 years he exercised a refining influence upon that art in Sydney. It was also in 1841 that we hear of a public performance of a sacred concert in Adelaide; a choral society gave concerts there in 1848. By 1859 Carl Linger was conducting a Handel festival in that city; his merits as a musician are to be gathered from his 'Song of Australia,' the best composition of its kind that has yet been locally produced. A further token of rapid progress in the same State is to be found in a 16 weeks' season of grand opera in 1861, when Adelaide contained only 18,000 inhabitants. In Victoria the Melbourne Philharmonic Society was formed under John Russell in 1853. The (old) Sydney Philharmonic Society was founded in 1854, and for years justified its existence by such productions as the *Messiah*, *Creation*, and *Elijah*; Anna Bishop (wife of Sir Henry Bishop, the composer) appeared among its soloists. At a musical festival held in Sydney 19-23 July 1859 the *Messiah* was revived at the opening of the hall of the university; at this festival the French musician Lavenu conducted 250 voices and an orchestra of 70, the prominent vocalists being Rosina Carandini (soprano) and Sara Flower (contralto); Melbourne sent her leading soprano, Mrs. Tester. In 1870—the middle year of two decades during which Italian and English opera flourished in Australia as it has never done since—there took place at the university of Sydney a musical festival at which appeared as vocalists Lucia Barrati, Lucy Chambers (an Australian contralto from the lyric stage of Italy), Neri (tenor), Contini (baritone), and Dondi (basso). Musical associations under various names—sometimes with mergings and consequent changes of title—inevitably grew up throughout Australia (a list of those at present existing is given below). In Adelaide a Philharmonic Society was performing the *Messiah* in 1862. In 1885 was established the present Royal Philharmonic Society of Sydney, which opened under Max Vogrich with Schumann's *Paradise and the Peri*, with Alice Rees as soprano. Vogrich was a pianist and composer who had toured Australia with Wilhelmj; later he married Alice Rees, whose brilliant career in Berlin and America closed with her return to Melbourne after an absence of 40 years; he was succeeded as conductor by Henri Kowalski, at one time pianist to Napoleon III. At Kowa'ski's second concert—the Christmas performance of the *Messiah* in 1885—the soloists included Nellie Armstrong (to become celebrated under the name of Melba), Marie St. Clair, Frank Boyle, and F. J. Hallewell (formerly of York Minster). The great soprano, then in her twenties, showed a marvellous fluency in 'Rejoice Greatly.' Kowalski returned to Paris to produce his opera *Giles de Bretagne*, but revisited Sydney and remained there for some years. In 1887 Roberto Hazon, for five years conductor at the Teatro Dal Verme at Milan, arrived in Sydney with Simonsen's Italian Opera company. He opened his career with the Philharmonic Society in 1889 by directing a festival at the Exhibition Building (when Charles Santley starred in his great rôle of Elijah), and for nearly 20 years exercised a profound influence. Meanwhile, during the Melbourne Centennial Exhibition (1888), the Victorian government brought out Mr. (afterwards Sir) Frederick H. Cowen and a few leading artistes, and the Cowen orchestra of 70 or 80 players drew crowds in that city, as it did also on visiting Sydney. After Cowen's departure enthusiasts in Melbourne guaranteed £5000 for two years, the Victorian government £3000, and subscriptions amounting to £5000 a year followed. The selection of a conductor was unfortunately left to a London committee, who engaged Hamilton Clarke, of the Lyceum and Haymarket theatres. Severe losses ensued, and though Julius Herz, the experienced conductor of the Melbourne Liedertafel, was called in, the venture failed. In the meantime G. W. Marshall Hall had been appointed (1891) to the new chair of music at the Melbourne university, and in 1893 he formed a symphony orchestra of 60 players, which gave six concerts annually. In Sydney the Amateur Orchestral Society was founded by Hazon in 1892 and conducted by him till his return to Milan in 1907. The title, however, was a misnomer, since it included regular professional players and a number of professional teachers. Many fine concerts were given, and among artistes who played concertos in association with it were Paderewski and Teresa Carreno. Hazon was succeeded by Gustave Slapoffski, and the old society survived until in 1908 the Sydney Symphony Orchestra, with 70 professional players, was started under W. Arundel Orchard, with Henri Staell as leader. This orchestra gave excellent concerts until 1919, when Verbrugghen (to be mentioned later), backed by heavy government subsidies, formed the all-the-year-round New South Wales State Orchestra; but the annual cost of the latter until 1922 had been £20,000 and the annual deficit about £11,000, and, despite its brilliant work, the orchestra was disbanded. During the earlier part of the time so far summarily treated Adelaide had been developing. In 1867 a season of grand opera was conducted by Herr Siede; other seasons, with various entrepreneurs and artistes, followed regularly from 1871, the Italian season of 1874 being of special note. In 1880 was formed the Adelaide String Quartette Club, which flourished with useful influence for six seasons. In 1883 the university of Adelaide received from Sir Thomas Elder a benefaction for the establishment of a scholarship in music at the Royal College, London. A chair of music—the first in Australia—had already been decided upon, and in 1884 the governor, Sir William C. F. Robinson (himself something of a composer) raised a provisional sum of £3000 towards the stipend of a professor, subsequently made secure by Sir Thomas Elder's generous endowment of £20,000. The first occupant of

the chair was Joshua Ives, Mus. Bac.; the present professor is Dr Harold Davies, who also directs a university conservatorium.

Since 1872 Melbourne town hall had possessed a fine organ, with David Lee as its first organist; unfortunately this was ruined by fire on 2 February 1925. In Sydney the new town hall, seating 3300 people and a choir, was opened on 27 November 1889. The first soloist to raise his voice in it (three days later) was Charles Santley, and W. T. Best, from St. George's Hall, Liverpool, began a series of recitals upon an organ which was then the largest in the world. This architecturally beautiful instrument was built by Hill and Sons of London, and possesses 128 stops, five keyboards, and pedal. The first city organist was Auguste Wiegand, a brilliant exponent of the French school, who held the post till July 1900. His successor Arthur Mason, an Australian, performed 450 programmes of remarkable range and variety. Since 1910 the organist has been Ernest Truman, an Australian composer and instrumentalist trained at Leipzig. Visitors who have played upon this great instrument have been Alfred Hollins, the blind organist of Edinburgh, in 1904, and E. H. Lemare, of St. Margaret's, Westminster, in 1906. At Adelaide the town hall organ was opened in 1877 with a performance by David Lee from Melbourne.

Musical Societies.—Something has already been said of musical societies. The chief of those in existence are here enumerated, but though they may appear to be confined to the capital cities, there are meanwhile flourishing bodies in all the larger towns. In *New South Wales*: The Royal Sydney Apollo Club, formerly the Sydney Liedertafel (founded in 1881 and renamed in 1916, with successive conductors J. A. Edwards, Max Vogrich, J. A. Delany, W. Arundel Orchard, and Alfred Hill, a New Zealand composer); the Sydney Madrigal Society (founded in 1908, with present conductor Frederick Mewton, organist of St. Andrew's Cathedral); the Welsh Choral Society; the Sydney Orchestral Society; the Harmonic Choral Society; the Orpheum Amateur Orchestral Society; the British Musical Society. In *Victoria*: The Melbourne Philharmonic Society (founded under John Russell in 1853, with subsequent conductors C. E. Horsley, Elsasser, David Lee, George Peake, and Alberto Zelman); the Oriana Madrigal Society; the Orchestral League of Victoria; the Melbourne Symphony Orchestra; the University Symphony Orchestra; the Royal Victorian Liedertafel (conductor Ernest Wood), a combination of the previous Melbourne Liedertafel and Metropolitan Liedertafel; the British Musical Society. In *South Australia*: The South Australian Orchestra (conductor W. H. Foote); the Adelaide Bach Society (Dr. Harold Davies); the Royal Choral Society; the Adelaide Glee Club; the Orpheus Society. In *Queensland*: The Brisbane Musical Union (George Sampson); the Brisbane Apollo Club (formerly Liedertafel); the University Choral Society; the Brisbane Austral Choir; the Queensland State and Municipal Orchestra (George Sampson). In *Tasmania*: The Hobart Orpheus Club (founded in 1877, present conductor C. M. Foster); the Hobart Choral Society; the Hobart Amateur Orchestral Society. In *Western Australia*: The Metropolitan Gleemen of Western Australia (founded in 1901 as the Metropolitan Liedertafel; present conductor A. J. Leckie); the Metropolitan Orchestral Society (H. Vowles); the Maylands Orpheus Society; the Fremantle Orchestral Society.

Grand Opera.—The first performance of opera in Australia was that of Sir Henry Bishop's *Clari, the Maid of Milan*, in 1834. Ten years later Rossini's *Cenerentola* was staged in Sydney with Edith Wallace (later Mrs. Wallace Bushelle) in the name-part. All early performances of the pioneer days were imperfect, but a few of the names survive to lend a personal interest. The Mrs. Stirling who sang in Auber's *Fra Diavolo* in 1845, and who in 1849 appeared as Maritana, was the mother of Nellie Stewart (q.v.), and the Madame Carandini (q.v.) of that company founded a musical family which flourished for another half-century. Sara Flower sang contralto rôles from 1850. Catherine Hayes, a famous Dublin soprano, sang in opera (1854) with Emile Conlon, a French baritone, and toured with great success in concerts. The output of operas not then so familiar as now was prodigious in spite of difficult conditions. Anna Bishop, accompanied by the harpist Chevalier Bochsa (who died in Sydney) made a stay of two years (1855 to 1857) and was the first to sing in Australia soprano rôles in *Lucrezia Borgia* and *Linda di Chamounix*. During the next two years Carandini's company and the Bianchi troupe performed seven more Italian operas new to Australian audiences. William Saurin Lyster, whose portrait now hangs in the Melbourne Art Gallery, dominated opera in Melbourne and Sydney as an impresario of enthusiasm and talent for 20 years (1861-80). He opened in 1861 with Lucy Escott (of Drury Lane) in *Maritana*, and two years later staged *Les Huguenots* for weeks. The 'first time' features of the following year were *Faust* and *Le Prophète*. John Hill came from London as conductor in 1866, and ten years later married in Melbourne Ilma di Murska, a world-famous Austrian soprano. He directed the music of *Semiramide* and *L'Africaine*. Armes Beaumont became one of Lyster's tenors, and had a long career, chiefly in Melbourne, both in opera and in oratorio. Lyster's company sailed to San Francisco, and at the end of their season came back with several new artistes. The only one still remembered is Lucy Chambers, an Australian contralto who returned from Italy and seems to have made a lasting impression. In the early seventies *Attila, Iona, William Tell, Crispino e la Comare* (Ricci), *I Lombardi*, and *La Juive* formed 'first nights,' and to these were soon added *Lohengrin* and *Aida*, Zelman conducting both in 1877. Revisiting London in 1879, Lyster returned with new artistes for *Carmen*, and during the season of 1880 introduced Annis Montagu and Charles Turner.

Two favourite artistes in opera, Signor and Signora Coy (tenor and soprano), arrived in 1871 and settled in Melbourne for many years, and the maestro Zelman became the father of the present orchestral conductor there. Martin Simonsen at this time began his career as a manager with French opera bouffe, in which his wife Fannie Simonsen starred in *The Grand Duchess* and other pieces; in 1875 Alice May (afterwards popular at the London theatres) headed a company in which *Dinorah* was the novelty. Ilma di Murska was brought from San Francisco by Henry Mapleson in 1876. In 1881 the Montagu-Turner company began a career of some years with ballad operas in English and some of the old Italian and French works. It was Simonsen who introduced Signor Hazon

(conductor) and a strong company of Italian artistes, who opened in Melbourne in 1886. The dainty Rebottaro, lyric soprano, and the Spanish basso Tomaso de Alba both settled permanently in Australia. Ciuti, the dramatic soprano of this fine combination, was quoted in Italy for the largeness of a voice of rich quality which had made her famous; Australian audiences heard and admired, though she was then past her prime. Amy Sherwin, known as 'the Tasmanian nightingale,' sang in a season of English opera; in later years she toured the world as a concert soprano, settled in London and filled soprano rôles with the Carl Rosa company, and, after twice visiting Australia, eventually retired, and has for some years been teaching in London. She married Hugo Gorlitz, for some years concert-manager for Paderewski and Kubelik. Louise Lablache (contralto) and Dimitresco (tenor) were in Australia at this time, and when they joined with Lilian Tree (as Marguerite) and Buzzi (as Mephisto), the cast was considered perfect. Later the two first sang at Covent Garden. Lablache possessed a heavy voice of richly sombre quality, and was tragically impressive as Carmen. While *I Pagliacci* and *Cavalleria Rusticana* were still the rage as epoch-making novelties in Europe, Williamson and Musgrove staged both works in Australia with an Italian troupe headed by Del Torre, the Italian soprano who had created Nedda and Santuzza in England. Mascagni's *L'Amico Fritz* was also staged. There was a new Italian company in 1892, remembered for a rich-throated warbling soprano, Tancioni Cuttica, who drew great audiences.

Twenty years having passed without Wagnerian opera, in 1900-1 Musgrove, an enthusiast for music, engaged Gustave Slapoffski, leader and occasional conductor of the Carl Rosa company, to form a combination for *Tannhauser*, *Lohengrin*, and *The Flying Dutchman*, all of which were splendidly staged and performed. Slapoffski conducted (also John Crook), and Mme Slapoffski and Ella Russell were the principal sopranos in various casts composed almost wholly of artistes from the Carl Rosa company. An immense repertoire was presented, during which Agnes Janson appeared in her Covent Garden rôle as Carmen. In the same year Williamson gave great operatic seasons under Hazon, during which De Vere Sapio, the American soprano, delighted Australia, as did also Carlo Dani and Dalia Bassich in Puccini's *La Bohème*, Verdi's *Otello*, Ponchielli's *La Gioconda*, and Giordano's *Fedora*, which were all new to Australia. In all 169 performances were given in ten months in Sydney alone, when the population was only half a million. Orchestras of 40 players were provided, a fact which marked the modern era. That number has been since maintained.

In 1907 a complete German company was formed by Musgrove, and audiences received *The Valkyrie*, as well as early Wagner, with enthusiasm; Humperdinck's fairy opera *Hansel und Gretel* was another new and enchanting feature. *The Valkyrie*, with its double cast and scenic and orchestral demands, formed a memorable production, dominated by Heinze, a great dramatic mezzo, as Brünnhilde. The following year Musgrove revived opera in English at the Sydney Criterion, bringing out the English tenor Wilson Pembroke, and advancing the youthful Rosina Buckman to the rôle of Maritana. This new National Opera company was far from strong. The first production of *Madame Butterfly*, with Bel Sorel and Amy Castles alternately in the name-part, brought back Hazon from Milan to Australia in 1910. The new opera was staged nightly in the two great centres for five or six weeks at a time, and was taken to New Zealand. In 1911 Melba realized her ambition of heading a great combination in her native country. The diva sang all her favourite rôles (with John McCormack as Romeo to her Juliet). Another great event was the first stage production of *Samson and Delilah*, with Zeni as tenor and the Countess De Cisneros in the mezzo rôle. Scandiani, the baritone, was much admired; some years later he became director of Milan Opera House. The great Polish dramatic soprano Korolewicz-Wayda electrified Australia's audiences with her glorious voice as La Tosca to Scandiani's Scarpia, and as Aida. The party included Rosina Buckman and Nance Maher in secondary rôles. Late in 1910 the Quinlan Opera company began with an English provincial season, a year later sailed for the Cape, and after a tour there reached Melbourne and Sydney in 1912. As they carried an orchestra of 50 players, a triple cast, and a numerous chorus, their expenses were prodigious, the fares to Australia amounting to £16,000. The flower of English opera singers had been got together. Some of these may be named — Agnes Nicholls, Jeanne Brola, Lalla Miranda, Edna Thornton, John Coates, John Harrison, Robert Parker, Allan Hinckley, Charles Magrath. Miranda, a Melbourne soprano whose sister Beatrice was for several years (including 1925) principal soprano with the Carl Rosa company in England, varied her career in France with full seasons at Covent Garden. Julia Caroli (sister of Daisy Davies), a Sydney-born singer who returned from Italy, sang several soprano rôles with the company. The new operas were *Tales of Hoffmann*, *The Prodigal Son* (Debussy), *The Girl of the Golden West* (Puccini), and *Tristan and Isolde*. *The Valkyrie* and Wagner's early operas, with Verdi's *Aida* as part of their Italian repertoire, were also staged, and the season was one sustained triumph.

In 1913 Thomas Quinlan, under a guarantee of the necessary subscription for so vast an undertaking, arrived in Melbourne again with a reconstructed company of 170 persons, 22 of whom were principals. Mention may be made of Felice Lyne, Jeanne Brola, Perceval Allen, Gladys Ancrum (sopranos), Edna Thornton (contralto), Maurice D'Oisly (tenor), Robert Parker and Graham Marr (baritones), and William Anderson (basso). The director Tullio Voghera returned for the Italian works, but Richard Eckhold, a celebrity who was with Wagner at Bayreuth in 1875, directed all the German masterpieces. Both in Melbourne and Sydney the four works of *The Ring of the Nibelung* —*The Rhinegold*, *The Valkyrie*, *Siegfried*, and *The Twilight of the Gods* (*Gotterdammerung*) —were splendidly staged, and aroused a rapturous admiration. *The Mastersingers*, with Robert Parker as Hans Sachs, was also new, and the modern methods of Charpentier in *Louise* did not lessen the ready appreciation of the work.

The great war banished opera until the Gonsalez company reached Australia by way of the East in 1916 and revealed some fine voices in Capelli (tenor), Scamuzzi (baritone), and Cacialli (basso) during a successful season. In 1919 Frank Rigo organized a season in Melbourne, in which Gertrude Johnson (soprano), Balboni and Lois (tenors), and Fillipini (bari-

tone) made successes. The Williamson season in English during the same year brought forward Amy Castles, Nellie Leach, Elsie Treweek, Leah Myers, Balboni, Cacialli, Carl Formes, and Fred Collier.

Melba had promised to give Australia a second memorable season, and J. Nevin Tait, John Lemmone, and the diva formed in Italy a splendid combination which reached Melbourne in March 1924. Nearly a score of operas (excluding Wagner) were beautifully presented with Melba and Toti dal Monte as the star attractions. Giordano's striking tragedy of the French Revolution, *André Chénier*, was the one great novelty, and *Don Pasquale*, unheard for a generation, was also produced. Melba opened the Sydney season brilliantly on 21 June in *La Bohème* with Dino Borgioli, a distinguished Italian tenor of great charm, as Rodolfo, and Alfred O'Shea sang the rôle with Melba during the season. The chorus consisted of 30 Australian female voices and 24 Italian tenors and basses, with an orchestra of over 40 players.

Comic Opera. The domain of comic opera, musical comedy, and burlesque is too comprehensive to be treated both briefly and adequately, since the second and third of these divisions depend too much upon stage-glitter, dancing, and the farcical humour of the 'book.' By their tuneful music, often of a high order, and by their wit in the libretto, the comic operas of W. S. Gilbert and Arthur Sullivan are placed on a pedestal apart. In Australia, as in England, this series has been regularly revived to crowded audiences from 1879 to the present time. Two only, *Ruddigore* and *The Grand Duke*, have failed to reach Australia, and from all accounts 'they never will be missed.' An imperfect performance of *H.M.S. Pinafore* had been given by Kelly and Leon a little earlier, but the record of Gilbert and Sullivan production of a high standard began in 1879, when J. C. Williamson acquired the rights; the whole series thereafter fell to him in all the States. Rose Hersee (of the Carl Rosa company) was the first Josephine, with Armes Beaumont as Rackstraw, and Williamson as Sir Joseph Porter. In 1881 Williamson produced *The Pirates of Penzance*; his troupe included Verdi, a grand opera baritone, as the pirate king. Nellie Stewart (q.v.) as Patience, and Howard Vernon and Verdi as the rival poets, were in the production of the new work in 1883. In 1885 Nellie Stewart played Phyllis in *Iolanthe*, with Robert Brough as the Lord Chancellor, and Emma Temple as Celia. At Christmas 1886 *The Mikado* opened the new Princess Theatre, Melbourne, with Alfred Cellier as conductor, Howard Vernon as Ko-Ko, Nellie Stewart as Yum-Yum, Frank Boyle as Nanki-Poo, John Forde in the name-part, and Alice Barnett as Katisha (which part she had created at the Savoy). In 1887, Nellie Stewart appeared as Aline in *The Sorcerer*, with Frank Thornton as John Wellington Wells. In the same year *Princess Ida* brought Leonora Braham, a fine singer, in her original Savoy part as Ida. In 1889 the music of *The Yeoman of the Guard* provided more than one stately aria, and the pathetic shading in the character of the piece was much appreciated when it was presented with William Elton as Jack Point, Clarence Leumane as Colonel Fairfax, Howard Vernon as Shadbolt, Nellie Stewart as Elsie Maynard, and Fanny Liddiard as Phoebe Meryll. All the exuberant brightness of *The Gondoliers* was enjoyed in 1891 with a good cast, including Elton, Sydney Deane, Vernon, Charles Ryley, Florence Young, Flora Graupner, and Violet Varley—the last two being small persons with large voices. *Utopia Limited*, the only weak opera of the series, was staged in 1906. *Trial by Jury*, written earlier even than *Pinafore*, was not staged by the Royal Comic Opera company until 1893, when it was put on and followed by *The Vicar of Bray*.

It will be observed that all these pieces have since been revived every three years or so, with new casts reinforced when necessary by new principals from the D'Oyley Carte companies on tour or at the Savoy theatre. George Lauri, a great favourite for many years, and a highly trained dancer, played many of these characters admirably. Gladys Moncrieff, whose beautiful voice won her a triumph in *The Maid of the Mountains* and similar pieces, began her career in her part of Josephine. In 1926 she went to London and made a success in the name-part of *Rikitiki* at the Gaiety.

During Gilbert-Sullivan seasons up to the present day various conductors of note have directed the music. W. H. Harrison, Alfred Cellier, A. W. Juncker, Léon Caron, Harry Burton, and Slapoffski are among the best known. Cellier, after conducting his opera *Dorothy* (1886) for part of the run in London, directed it in Australia. Juncker, long resident in Australia, is a composer known for his opera *The Romance of Corsica*. He interpolated his song 'I was Dreaming' for Nellie Stewart in *Ma Mie Rosette* as applicable to the plot of that opera, and it became the rage throughout Australia. Caron was one of Lyster's conductors in 1880. This genial French artist was for many years with the Royal Comic Opera company until his death in 1905. Since 1904 Andrew MacCunn has conducted practically all the light operas by Lehar and Oscar Strauss, many musical comedies, and *The Beggar's Opera*.

Visiting Celebrities. As will have appeared from the preceding matter, Australia has been frequently visited by musicians of the very first rank, as well as by a host of others of more or less considerable standing, from Great Britain or elsewhere. Many of these have already been incidentally mentioned, and during the present century their number has been so great that the tabulation given below must suffice. For the years preceding 1900 there should be added, among singers, Carlotta Patti, the sister of Adelina (1880), and Kate Thayer (1881). In 1890 came Lilian Tree, Antonietta Link, and Mme Patey; in 1892 Foli, the world-famed basso, and Orlando Harley (American tenor); in 1893 Antoinette Sterling; in 1894 were grouped Clementine de Vere Sapio, Belle Cole, and Charles Magrath; in 1895 Alice Esty, Robert Cunningham (born at Hobart), and Alec Marsh—all from the Carl Rosa company—with Mme Enriquez, appeared in all the Australian centres; in 1896 Mme Steinhauer, a Danish soprano, arrived, and in the same year an English quartet consisting of Emma Thudicum, Marion Mackenzie, Edward Branscombe (Westminster Abbey), and Douglas Powell. The quartet at the Albani festival of Sydney in 1898 brought Albani, Sarah Berry, Orlando Harley, and William Paull (a Carl Rosa baritone). In 1900 Jessie King, an English mezzo-soprano of eminence, sang in Verdi's *Requiem* and Coleridge-Taylor's *Hiawatha's Wedding Feast*.

Of visiting instrumentalists for the same or an earlier period only bare mention can be made.

1. Ox-eye Herring (*Megalops cyprinoides*). One-sixth natural size.
2. Sergeant Baker (*Aulopus purpurissatus*). One-seventh natural size.
3. Freshwater Catfish (*Tandanus tandanus*). One-seventh natural size.
4. Nannygai (*Trachichthodes affinis*). One-fifth natural size.
5. Red Perch (*Caesioperca lepidoptera*). One-fourth natural size.
6. Banded Sea Perch (*Gilbertia annulata*). One-third natural size.
7. Murray Cod (*Oligorus macquariensis*). One-eighth natural size.
8. Golden Perch (*Plectroplites ambiguus*). One-sixth natural size.
9. Sand Whiting (*Sillago ciliata*). One-fifth natural size.
10. Tailor (*Pomatomus saltatrix*). One-sixth natural size.

The pioneer violinist to tour the country (including bush towns) was Miska Hauser in 1854; the first woman violinist to come from Europe for the same purpose was Jenny Claus (1872), a brilliant pupil of Vieuxtemps. Arabella Goddard, the pianist, arrived in 1873; Levy, the star cornet-player, in 1877, Camilla Urso, the Italian violinist, in 1879 (with Benno Schereck, subsequently of Melbourne, as pianist). In 1880 Henri Ketten and Henri Kowalski (French pianists) appeared; in 1881 Wilhelmj, the German violinist, soon followed by Remenji, the Hungarian; in 1885 John Kruse, a Melbourne violinist, returned to his native city after an absence of ten years. The visitors of the next decade included Madame Schiller (pianist); Sir Charles and Lady Halle (Mme Norman Néruda), who drew crowds throughout a prodigious tour; W. T. Best, the organist; Ovide Musin, the Belgian violinist; Mark Hambourg (1895), who made several subsequent tours with his brothers Jakoff (violin) and Mischa ('cello); Chevalier De Kontski, an octogenarian pianist said to be the last actually taught by Beethoven and of note for the popular piece *Le Réveil du Lion*. Elsie Stanley Hall (Australian pianist) returned from Berlin as the only British student who had won the Mendelssohn state prize there; in later life she taught the piano to the Princess of Wales at St. James's Palace.

Most of the stars who have visited Australia during the present century have been under the management of J. and N. Tait. John Lemmone directed the Paderewski recitals and all Melba's later concerts, including her Red Cross tour (by which enormous sums were raised), and her People's Concert season with the New South Wales State orchestra in Melbourne and Sydney; Una Bourne was the pianist. Fred Shipman brought over Mischa Elman (Russian violinist), Nordica, Dufault, and several other stars; Daniel Meyer brought Levitski and also D'Alvarez. In recent years E. J. Gravestock has become prominent as an entrepreneur, handling Buckman-D'Oisly, Gerardy, Lipkowska, Hackett, and Stella Power. The list of stars is as follows:

1901 and 1923. Jean Gerardy (Belgian 'cellist).

1903. Edward Lloyd (tenor); Mark and Boris Hambourg (pianist and 'cellist); the Westminster Abbey Glee Party (Edward Branscombe conductor); E. H. Lemare (English organist); Ada Crossley (Australian contralto), with Percy Grainger (Australian pianist).

1904. Ignace Jan Paderewski (Polish pianist); Alfred Hollins (blind organist); Watkin Mills (English basso) and party.

1905. The Parkina-Foldesy concert company, with Margaret Thomas.

1906. Andrew Black (English baritone); Blanche Arral (French prima donna).

1907. Teresa Carreno (pianist); Marie Hall (English violinist).

1907, 1914, 1921, and 1925-6. Clara Butt and Kennerley Rumford and party.

1907. Melba, with Una Bourne (Australian solo pianist), Andrew Black, John Lemmone, and Harold Whittle (Australian pianist).

1908. Jan Kubelik (Bohemian violinist); the Royal Welsh choir (W. Thomas conductor); Katherine Goodson (English pianist).

1908, 1914, 1917, and 1921. The Cherniavsky trio (violin, piano, and 'cello).

1909. Melba, in concerts with orchestra; Amy Castles (soprano) with Peter Dawson (bass), both being Australians returned from Europe.

1910. Emma Calvé (world-famous Carmen), with Signor Gasparri (Italian tenor) and Jaques Pintel (Russian pianist).

1911. Leonard Borwick (English pianist); the Sheffield choir (Henry Coward conductor); Ben Davies (English tenor), with Esta D'Argo (Australian soprano) and Edward Goll (Bohemian pianist).

1912. Eleanora Cisneros (American operatic mezzo), with Paul Dufault (French-Canadian tenor), James Liebling ('cellist), and Harold Whittle (Australian pianist); Louisa Kirkby-Lunn (Covent Garden contralto), with William Murdoch (Australian pianist from London); Thuness Koverich (Hungarian violinist), with Leah Myers (Australian soprano, who has since adopted the name of Leah Rusel Myre in Europe).

1913. Adelina Genée, with a Russian corps de ballet and Mlle Schemiz and M. Volinin, and orchestra conducted by C. J. M. Glaser; Walter H. Thorley (English pianist); Lillian Nordica (American dramatic soprano), with Paul Dufault (French-Canadian tenor); John McCormack (Irish tenor, naturalized American).

1914. Harold Bauer, German pianist; Mischa Elman (Russian violinist, since 1920 naturalized American), with Eva Gauthier (mezzo-soprano) and Percy Kahn (pianist-composer); Peter Dawson (Australian baritone); Paul Dufault (French-Canadian tenor), with Pauline Bindley (Australian soprano), Ernest Toy (Australian violinist), and Jaques Pintel (Russian pianist).

1915. Robert Parker (American operatic baritone), with Florence Scapini (violinist) and Harold Whittle (pianist); Amy Castles (Australian soprano), with John Amadio (flautist) and Bryce Carter ('cellist).

1916. Max Selinsky (Russian violinist); Alfred Mirovitsch (Russian pianist), with Michael Piastro (Russian violinist).

1919. Melba in concerts, prior to leaving for London.

1920. Benno Moiseiwitsch (Russian pianist), with Daisy Kennedy (Australian violinist), Hubert Eisdell (English lyric tenor) and Alma Garrett (contralto); Amy Evans (Welsh soprano), with Fraser Gange (Scotch basso).

1921. Jascha Heifetz (Russian violinist), with Samuel Chotzinoff (pianist); Mischa Levitski (Russian pianist); Melba, in concerts.

1922. Jascha Spivakovsky (Russian pianist); Melba, in concerts for the people, with Una Bourne, John Lemmone, and State Orchestra; the Sistine Choir of 60 male voices (Monsignor Rella conductor); Toscha Seidel (Russian violinist), with Frank Hutchens (Australian pianist); Melba (farewell); Marguerite D'Alvarez (contralto), with Oscar Wagner (American pianist); Rosina Buckman (Australian operatic soprano), with Maurice D'Oisly (tenor), Adelina Leon ('cellist), and Percy Kahn (pianist).

1922 and 1925. Paul Althouse (American tenor), with Arthur Middleton (baritone).

1923. Lydia Lipkowska (Russian soprano), with A. Sverjensky (pianist); the Westminster Glee Singers (Edward Branscombe conductor); Melba, in concert season, with Prince Obolensky (basso), John Lemmone (Australian flautist), and Lindley Evans (Australian pianist).

1924. Charles Hackett (American tenor), with Yovanovitch Bratza (Servian violinist); Mieczyslaw Munz (Polish pianist from America); Zachariwitsch (Russian violinist), with Cellini (English tenor) and Cimara (pianist); William Hughan (Scottish song entertainer); Paul Vinagradoff (Russian pianist); Amy and Eileen Castles (Australian operatic sopranos), with Signor Capelli (operatic tenor) and Alfred Bartlemann (Australian baritone).

1925. Amelita Galli-Curci (Italian soprano), with Homer Samuels (pianist) and Manuel Berenguer (flautist); Elsa Stralia (Australian dramatic soprano), with Bessie Griffiths (Australian 'cellist) and Arthur Jordan (English tenor); Fritz Kreisler (Austrian violinist), with Lamson (English pianist); Dorothy Helmrich (Australian soprano, after long absence in London); the Sistine soloists (eight) in opera selections.

1926. Marie Antoinette Aussenac (French pianist), with the Butt-Rumford company; Anna Pavlova (Russian dancer), with Laurent Novikoff, in Russian ballet, and with orchestra conducted by Lucien Wurmser; the Don Cossacks choir (Serge Jaroff conductor); Toti Dal Monte (Italian lyric soprano), with Auguste Benf (operatic baritone) and William James (Australian pianist back from London); Percy Grainger (Australian pianist, now a naturalized American); Wilhelm Backhaus (German pianist); Feodor Chaliapin (world-famous Russian operatic bass-baritone).

Visiting Choirs.—Notwithstanding the very high cost of transporting choirs from Europe, such enterprises have several times been carried out; in the case of the Quinlan operatic tour of 1913 both chorus and orchestra were imported. In 1902 Edward Branscombe brought the Scarlet Troubadours, and in 1900, 1904, and 1922 toured the world with the well-trained Westminster Glee Singers, who proved very popular with madrigals, old English glees, and sacred numbers. In 1911 Dr. Charles Harriss (Canadian) brought 200 singers selected from the Sheffield Choir, with Dr. Henry Coward at their head. Melbourne, Sydney, Brisbane, and Adelaide were visited. As an example of the operations of this choir, its work in Sydney may be recorded. The Sydney festival opened (13 June 1911) with the *Messiah,* the soloists being Jenny Taggart, Gertrude Lonsdale, Henry Turnpenny, and Robert Charlesworth. In all 10 concerts were given, at which were presented *The Dream of Gerontius, Pan* (a symphonic choric idyll by Charles Harriss), Parry's *Blest Pair of Syrens*; Beethoven's *Choral Symphony* with the Sydney Symphony Orchestra under Joseph Bradley; Bach's motet for double-chorus 'Sing Ye to the Lord' and Sullivan's *The Golden Legend,* under Dr. Coward; the *Elijah* by the Sheffield singers and the Sydney Philharmonic; a coronation concert of miscellaneous pieces, and an open-air coronation celebration in Martin-place (21 June). The Sistine Choir was brought out by E. J. and D. Carroll and opened in Melbourne (15 April 1922) under the baton of Monsignor Rella. The full choir of men and boys, 50 in all, wore their purple cassocks. The programme of liturgical music from Palestrina to Perozi was exquisitely rendered; 17 concerts followed, and a second long season some months later. The Sydney season drew crowds for 21 concerts. Later in the year the boy choristers returned to Rome; the tenors and basses remained for a time and with operatic programmes filled the largest halls. The Russian 'Don Cossacks,' under Serge Jaroff, came in 1926 and proved a most harmonious male-voice choir in Russian folk-melody and anthems; though there were some fine individual voices, their forte was essentially ensemble singing. The Fisk Jubilee Singers first toured Australia in 1887 and captivated audiences with the quaint charm of their 'Steal away to Jesus,' 'I'm rolling through an unfriendly world,' and the like. All the States were visited more than once.

Musical Training: Conservatoria.—The foundation of chairs of music in the universities of Adelaide and Melbourne has already been mentioned. In connection with each there has been established a conservatorium; the similar institution in Sydney is a 'State' conservatorium without relation to the university. Three years after his appointment to the chair in Melbourne Professor Marshall Hall formed (1894) and directed a conservatorium in conjunction with it—the first experiment of the kind in a British university. Upon his vacating the chair, he was succeeded in both functions by Franklin Peterson, who died in 1914. Marshall Hall was then reappointed, but he also died in 1915, and was succeeded by his chief subordinate, W. A. Laver, who held office till 1925. The present professor and director is Bernard Heinze, a former student of the conservatorium who has spent some years in England and on the continent of Europe. The principal teacher of singing is Agnes Janson, the famous Swedish Carmen. To Marshall Hall the musical world of Melbourne has reason to be grateful; his undoubted musicianship, his strong personality, and his unbounded energy and enthusiasm had a very pronounced influence on the musical development of the State. Professor Peterson, in his turn, played a great part in shaping the public examinations in music; to Professor Laver is largely due the creation of a sound school of pianoforte. Students below a certain standard are not accepted at the conservatorium, and the majority are engaged in following the full course for the diploma or degree. The degree of Mus. Bac. has been conferred on 45 students, and about 130 have taken the diploma. The great majority of these have subsequently taken up teaching work throughout Australia, and some have gone abroad and made their mark; among the latter may be named Florence Austral, Kate Samuels, Elise Nerida Steele, Anne Williams, Bernard Heinze (now the professor), Fred. Clutsam, and William James.

On leaving the university (1900) after his first tenure, Marshall Hall started an institution commonly known as the Albert Street Conservatorium, in which Melba interested herself, giving lessons in it to students of promise at times between her long absences in Europe and America. Since 1914 it has been under the direction of Fritz Bennicke Hart.

The Adelaide Conservatorium was established by the university in 1898, absorbing the staff of the Adelaide College of Music, which had flourished for many years under I. G. Reimann. The present director is Professor Harold Davies, with a staff of 19 teachers; the number of students is approximately 650.

The New South Wales State Conservatorium—which is a branch of the education department and is financed by an annual parliamentary appropriation, with its revenue from fees credited against such grant—was opened in 1916, with Henri Verbrugghen, a Belgian violinist long resident in Glasgow, as principal. With him he brought the three other players of his string quartet, Jenny Cullen, David E. Nichols, and James Messeas—a first-rate combination of many years' standing in Glasgow. (An already existing Austral Quartet of capable artists, headed by Cyril Monk, was thereby displaced; nevertheless fine concerts were given at the Beale salon by Henri Staell, W. J. Grieves, H. T. Kelly, and Bryce Carter.) Verbrugghen proved himself a brilliant orchestral conductor, formed a small choir for the study of Bach, and gave lectures. After his departure (1922) for America, where he was appointed conductor of the Minneapolis Orchestra, he was succeeded (1923) by W. Arundel Orchard, who gradually formed an orchestra partly composed of professional players but with an infusion of advanced students taking the work as part of the academic curriculum. There are at present over 1500 students on the conservatorium roll. The conservatorium is housed in a picturesque struc-

ture fashioned from what were once the stabling quarters of government house.

Examinations.—Various English bodies visit Australia to hold examinations in all branches of music. Most prominent among these are the Associated Board of the Royal Academy of Music and the Royal College of Music, which is a chartered institution, and Trinity College, which is affiliated with London university. These external agencies, however, have naturally been more and more replaced by arrangements within Australia itself.

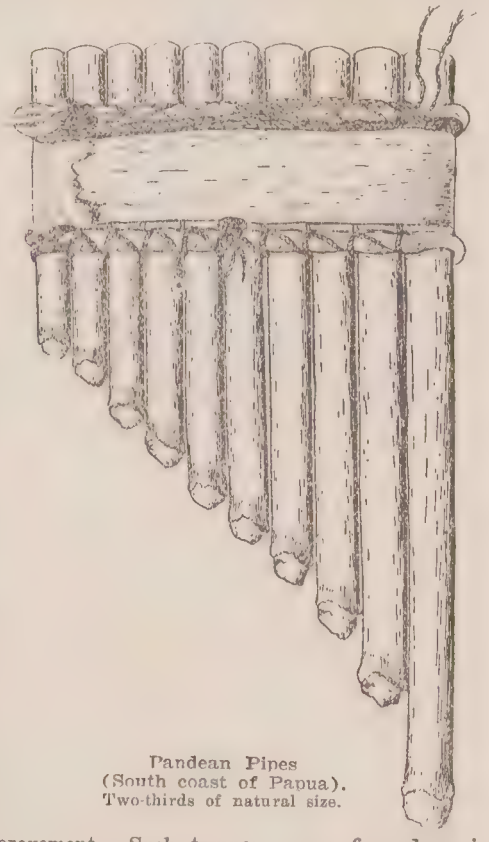
In 1887 the university of Adelaide inaugurated under the direction of its then professor, Joshua Ives, the first public examinations in music held in Australia. These were followed in 1902 by the university of Melbourne, which instituted similar tests conducted by a board under its authority. For the first examination, held in that year, there were 431 entries; an exhibition, providing three years' tuition at the University Conservatorium, was offered for competition. The scheme was almost immediately extended to Tasmania with the sanction of the university of that State. In 1906 the universities of Melbourne and Adelaide entered into an agreement for the joint conduct of a common scheme, and in this the universities of Tasmania and Queensland became partners in 1911, and the university of Western Australia in 1915. In 1917 Verbrugghen, of the New South Wales State Conservatorium, was so impressed with the results of the partnership that he obtained the consent of the education department to making the conservatorium also a sharer in the scheme, which thus became pan-Australian. A central board, known as the Australian Music Examination Board, was then established and in 1918 held its first meeting in Sydney. In 1925 the 'Art of Elocution' was added to the list of subjects, and in that year the aggregate of entries for examination in the whole of Australia was 14,369

Musical Competitions.—Competitions in music have been held for many years throughout all the States, probably the most important being the 'South Street, Ballarat' and the 'Australian Natives' Association,' both in Victoria. The former are on a very large scale and attract thousands of people to Ballarat every year. Many singers and instrumentalists owe their success to the encouragement received at these meetings, which set a useful standard.

Australians distinguished in Music.—Among Australians who have gained distinction in the art centres of the musical world are:—Dame Nellie Melba, Florence Austral, Frances Alda, Eda Bennie, Lucille Benstead, Pauline Bindley, Bertha Bird, Eugenie Boland, Una Bourne, Rosina Buckman, Julia Caroli, Amy, Dolly, and Eileen Castles, Ella Caspers, Hope Charteris, Ada Crossley, Esta D'Argo, Beatrice, Bessie, and Muriel Griffiths, Gertrude Johnson, Daisy Kennedy, Rene Maxwell, Myrtle Meggy, Lalla and Beatrice Miranda, Leah Myers, Eva Mylott, Marie Narelle, Stella Power, Kate Rooney, Bertha Rossow, Patti Russell, Frances Saville, Evelyn Scotney, Clara Serena, Amy Sherwin, Elise Steele, Elsa Stralia, Elsie Treweek, Gladys Verona, Strella Wilson; George Boyle, Fred Collier, Robert Cunningham, Peter Dawson, A. H. Gee, Reginald Gooud, Eric Hayne, Frank Hutchens, Walter Kirby, John Kruse, John Lemmone, Godfrey Ludlow, E. E. Mitchell, William Murdoch, Browning Mummery, Alfred O'Shea, Lempriere Pringle. Jan Rudenyi (Pechotsch), Walter Sherwin, Cecil L. Sherwood, Lawrence Godfrey Smith, Otto F. Sobell, Horace Stevens, and Ernest Toy.

Australian Composers include:—May Brahe, Mona McBurney, Roy Agnew, Arthur L. Benjamin, George F. Boyle, H. J. Brewster-Jones, George H. Clutsam, David John Coutts, Percy A. Grainger, Fritz B. Hart, Claude Haydon, Alfred Hill, Ernest Hutcheson, Herbert Howells, William G. James, Louis Lavater, G. W. L. Marshall Hall, W. Arundel Orchard, Henry Tate, and Ernest Truman.

Music, Aboriginal.—Among primitive peoples music developed as an accompaniment controlling and stimulating religious or ceremonial dances. In its earliest phases, it was therefore entirely rhythmic. Among the Australian natives the clapping of hands, or the striking of two boomerangs or sticks together, may be considered the most primitive methods of accompaniment for this purpose. An improvised drum in the shape of a skin stretched across the knees, and beaten with the fists, was a technical improvement. Such tympana were figured as in use at Port Jackson in 1798 (Collins), and were observed in Western Australia before 1839 (Ogle). Other time measurers are the carved leaf-shaped 'tatty sticks' and other staves beaten together, and the musical 'coondie,' a club with a serrated edge on which a boomerang is rasped up and down. The time-beating is usually performed by the women, who sit while the dances are in progress.



Pandean Pipes
(South coast of Papua).
Two-thirds of natural size.

Apart from these the aboriginal has shown little inventive genius in the manufacture of instruments of music proper. The 'bull-roarer' (see ABORIGINES) may perhaps be considered such. It is found over the greater portion of

Australia, and its counterpart is known from many lands. It would appear that the few instruments known, such as the corroboree-trumpet, or 'drone-pipe,' of the northern parts of the continent, the emu-decoy of western New South Wales, and the bone whistles of north-eastern Queensland, have the doubtful quality of producing but one note. The drone-pipe is made

Conch Trumpet (New Guinea).
About two-fifths of natural size.

either of bamboo with the internodes removed, or of a hollow sapling. Intonation, which is taught at the initiation ceremonies, is given by a vibratory movement of the lips. In Groote Eylandt such an instrument is part of the equipment of every camp, and the booming sound goes on throughout the night, one native relieving another. Its cessation would indicate that all the camp was asleep, and the opportunity might be seized by a hostile party. The bone whistles of Queensland resemble units of a pan-pipe, and are blown across in the same manner. Of later introduction are whistles, formed from a folded leaf, that of the cultivated lemon giving the best results.

Vocal music, though largely indulged in, shows no advancement from the elemental. Most of it consists of a low monotonous chant, with very little range. Many natives can improvise, and a man often whiles away his time with compositions of his own on themes of personal interest. The vocal scores of some of the corroborees are transmitted from one tribe to another where not a word is understood. A new song is highly appreciated, and a travelled aboriginal sometimes brings back a few of the latest 'ditties,' with which he 'astonishes the natives.' In the corroboree songs (says Mathew) 'the modulation is easy and gradual, the music rising or falling in semitones, save when, after a gradual descent, there is a sudden vocal leap of an octave upwards. The close of the piece will be indicated by three great yells, which do duty for the crashing music indispensable to finish off most of the compositions in the repertoire of civilization.' Voice production of a novel kind is described by a native of Cairns, Queensland. A certain kind of small brown frog, carefully selected, is placed in a vessel containing a small amount of water, and is left until it dies and the liquid becomes discoloured with age. The black 'Caruso' then drinks the liquid, eats the frog, and thereby gains the much-desired clear strong voice.

The wail for the dead by the women at sunset —which can, indeed, hardly be called music— is pensive and melancholy in the extreme. It rises and falls uncannily on the still evening air, and, once heard, becomes indelibly impressed upon the memory.

Music, Papuan.—The music of New Guinea, whether instrumental or vocal, is more advanced than that of the Australian aborigines. The instruments employed are more various and show a much higher degree of culture. For rhythmic purposes the chief are drums and rattles. Drums are found in great variety. In some of the villages on the north-eastern coast there are communal drums, very massive and highly carved; cut from a solid log of hardwood and laboriously hollowed out through a longitudinal slit, they are used for signalling or sounding alarms, and are beaten with a pounder-like baton. The dance-drum (or 'tom-tom') is hollow, and of the 'hour-glass' type. In the Gulf of Papua the end opposite to the tympanum is carved to imitate the mouth of a crocodile. An exceedingly large bell-mouthed variety occurs among the Tugeri tribe, west of the Fly River. A small straight-sided instrument, resembling a miniature cannon, is made in the Trobriand group. The timpani are usually made of the skin of snake or lizard, but a wallaby pelt is sometimes used.

A rattle used at dances on the Fly River is formed of dangling seed-pods and crabs' claws attached to a bent cane. On the upper waters of the same river human skulls are used for the same purpose. After decapitation the skull is removed through a cut at the back, cleaned, and replaced in the skin, a small pebble being inserted in the brain-cavity before the final stitching. In the Torres Straits rattles made of seeds of the *Pangium edule*, fastened to a circular frame, form part of the initiation equipment, and in the same islands clappers of split bamboo are used for rain-making.

Among musical instruments proper the triton shell (or 'conch-trumpet') is known in New Guinea. The shell has a hole drilled in the spiral chamber, through which a deep whistling sound can be produced. Mouth whistling is also practised; one tribe, living in the hinterland of Redscar Bay, whistles the tribal melodies in chorus. Pandean pipes, known from the Sepik and Markham rivers, consist of only three or four modulated tubes, differing in this respect from the multiple pipes of the southern coast of Papua and Melanesia generally. The 'jews' harp' (or 'jaw harp,' to give the instrument its original New Guinea name) is considered a musical toy. Made of palm-wood or bamboo, slightly concave, it resembles an elongated pen-nib. Two strips represent the pen-point, these being tied together at the ends and enclosing a free and splinter-like 'tongue;' a cord is attached to the butt-end. The instrument is placed against the mouth, breathed upon, and kept in a state of vibration by a constant jerking of the cord. A single-string musical bow has been observed on the Sepik River, and a peculiar variety of bamboo drone-pipe on the Markham. This latter is not blown with the mouth, but struck on the knee, the percussion causing the cylinder to emit a booming noise. The 'bull-roarer' (see ABORIGINES) is known from several regions on the mainland, and also in the islands of Torres Straits; wherever found, it is associated with ceremonies, and venerated accordingly. Palm-wood is the material favoured in its manufacture, but a form in light wood from the upper Fly River is covered also with the skin and feathers of a bird of paradise.

Vocal music is largely indulged in, but in this connection S.H. Ray states:

I doubt whether it is possible to give a literal translation of any New Guinea song. A native would probably find it very difficult to express the meaning (if it were known to him) in the language of everyday life. All these songs naturally belong to the older stratum of the language. Associated with traditional customs, they have been accepted and used by succeeding generations without much enquiry into the meaning of the words used. The constant and rapid change usual in the language of savage races would soon cause many of the words to become obsolete, and in time their significance would be entirely forgotten. Many travellers in New Guinea have given specimens of songs, but all have failed to explain the language used.

Some of the vocal music consists of chants sung during ceremonies, and even when performing ordinary acts of life, such as planting and harvesting yams. As regards the quality of vocal performances in Papua R. A. Vivian records:

When performing (i.e. singing), the brown liedertafel has no conductor, but takes its cue from a recognized leader, and under him the body of singers was found to be as happy in its barbaric glees and madrigals as it was sympathetic in its folk songs, rhythmic in its hunting chorus, and defiant in songs of war. One of the numbers bore a striking resemblance to accompaniment by a bass violin, the effect being obtained by deep-throated humming at certain intervals in the song. Although harmony did not appear to receive any recognition, it occasionally obtruded itself, very likely by chance. Combined, the voices produced a rich volume of sound, unison at times being especially pleasing. Many of the melodies were of a composition far from simple. W.W.T.

Muskrat-kangaroo, vernacular name of a species (*Hypsiprymnodon moschatus*) of the marsupial family Macropodidae, which differs remarkably from other members of the family. The head and body together are about 10 inches long, the tail about 6½ inches. The fore- and hind-limbs are sub-equal, the latter not being specially developed—as are those of other members of the family—for bipedal leaping progress. The hind-limbs are also remarkable because the first toe (which in other Macropodidae is aborted) is well-developed though clawless, and can be opposed to the other toes, and the fourth toe does not greatly predominate in size over the others, as it does in kangaroos and wallabies. The tail is naked and scaly. The muskrat-kangaroo has been found hitherto only in the dense and damp scrubs of the Herbert River district of Queensland. Chiefly diurnal, it procures its food by turning over debris in search of insects, worms, and tuberous roots, and frequently eats palm-berries. The nest is round, and formed of leaves. W.A.H.

Musk Tree. See OLEARIA.

Musquito, an aboriginal belonging to the Broken Bay tribe in New South Wales, who

after long association with convicts was convicted of the brutal murder of an aboriginal woman and transported first to Norfolk Island and then (in 1813) to Tasmania. He was assigned as a servant to Kimberley of Antill Ponds, and transferred from him to Edward Lord, but became famous as a tracker and was employed by the police against the bushranging gangs. In October 1817 Governor Sorell stated that he was sending Musquito who had been 'extremely useful and well conducted' to Sydney in the *Jupiter*, and bespoke Macquarie's consideration for him on account of his services. If Musquito went to Sydney, however, it was not long before he returned to Hobart. In 1818 he was instrumental in tracking down Michael Howe (q.v.), but soon afterwards found himself in danger from convicts—and even from some prisoners used as police—who sympathized with Howe, and was sent to Hobart. Here, having no employment and no friends, he gathered round him a number of aboriginal refugees who had broken tribal laws, and formed them and other native ne'er-do-wells into a 'Tame Mob' which in 1819 began a series of attacks on white settlers. In 1820 the mob infested the Oatlands district, and next year moved eastwards to Oyster Bay, where Musquito obtained a great influence over the previously quiet Oyster Bay tribe. In this lies his importance—that he introduced among the shy and comparatively inoffensive Tasmanian natives the aggressiveness and ferocity of the mainland tribes; he also introduced the boomerang (which was not a Tasmanian weapon), but it does not seem that he persuaded his new companions to adopt it. It is fair to add that he is said to have persuaded the Oyster Bay tribe to indulge in a little rough farming, and that according to West Gilbert Robertson, who knew Musquito personally, regarded his misdoings as retaliation for previous ill-treatment. During 1820-23 the raids of his followers became so unbearable that great efforts were made to catch him, and in August 1824 a local aboriginal usually known as 'Tegg' or 'Teague' guided police to his lair, shot him in the thigh, and brought him to Hobart. On 1 December 1824 he was convicted of a murder committed at Grindstone Bay (south of Oyster Bay) in 1823, and on 25 January 1825 was hanged at the Cascades near Hobart. His example, unfortunately, was infectious. Tegg, failing to receive a promised reward at once, took to the bush with another aboriginal mob, and committed several atrocities, but after a time surrendered and was pardoned. One of Musquito's comrades, 'Black Tom,' was captured in 1823 and sent to Macquarie Harbour, but escaped and joined the 'Abyssinian mob' which infested the Shannon valley; he came in under a conciliatory offer made by Governor Arthur in 1828, and died at Emu Bay in 1832. It is usually stated that he was 'Black Tom Birch,' a native trained and much trusted by Thomas William Birch; but this is not so.

See Bonwick's *Last of the Tasmanians*, and West's *History of Tasmania*.

Mutton-birds. See PETRELS.

Myall. See ACACIA.

Mycetozoa or **Myxomycetes,** commonly known as slime-fungi, are minute organisms on the border between the animal and vegetable kingdoms, characterized by the constant sequence of three main stages in their life-history: (1) the firm-walled spore gives birth to a swarm-cell; (2) the swarm-cells coalesce to form a wandering plasmodium; (3) the plasmodium concentrates to form either sporangia enclosing numerous spores (Endosporeae), or sporophores with spores on their outer surface (Exosporeae). During the plasmodia stage they resemble low forms of animal life, as amoebae, but when mature they are very like fungi. From these, however, they are distinguished in that their vegetative body consists of naked protoplasm without a firm membrane: they lack the cellular mycelium of the true fungi.

Many species are commonly found in dense forests or damp gullies on decaying wood, leaves, manure or grass. The dense masses of spores are said to injure vegetation by a process of suffocation; and it is recorded that horses and other animals have died from the effects of eating these spore-masses adhering to pasture. *Physarum cinereum*, during damp, warm summer weather, occurs in patches of one to five feet in diameter on couch or buffalo grass in our suburban gardens, and on grass-lands throughout Australia. The cosmopolitan Flowers of Tan (*Fuligo septica*), which in the plasmodia stage somewhat resembles the broken yolk of an egg, spreads over tan-beds in hot-houses or frames. *Mucilago spongiosa*—well known as a cause of injury to hay-crops in other countries—has been occasionally collected in Australia. The disease known as club-root or finger-and-toe, amongst cabbages and turnips, is caused by *Plasmodiophora brassicae*. Another species (*Spongospora subterranea*) causes a disease in potatoes known as corky-scab. Closely related to these are the slime-moulds which cause the malaria that is transmitted by the mosquito to man (see TROPICAL MEDICINE), and the Texas fever that is transmitted by the tick to cattle (see CATTLE-TICK). The writer has received the plasmodium of *Lycogala epidendrum*, found in sawdust at Scheyville; mature specimens were collected from the Sydney botanic gardens, the National Park of New South Wales, and Russell Falls in Tasmania. Upwards of 50 genera and 400 species are known to science, of which some 27 genera and 82 species have been recorded from Australasia.

E.C.

Myoporaceae, a family of shrubs or small trees, mostly indigenous to Australia, containing a limited number of species that extend to Malaysia, Oceania, and tropical Africa. There is also a tropical American genus with one species. The flowers are axillary, irregular, solitary or in clusters of 2, 3, or more; calyx toothed or divided into 5 (rarely 4) segments; corolla with 4-5 lobes, more or less two-lipped; stamens usually 4, in pairs, inserted in the corolla-tube; fruit a drupe, dry or succulent; seeds solitary; leaves alternate, undivided. The most important genera are *Myoporum* and *Eremophila* (q.v.).

Myoporum, a genus of the family Myoporaceae, a few species of which are found in the Indian Archipelago and the Pacific islands, and one in tropical Africa; the rest are endemic in Australia. The flowers are small, usually white; calyx divided to the middle; corolla-tube usually bell-shaped, with 5 nearly equal lobes; fruit a more or less succulent drupe, *M. deserti* is the 'Ellangowan Poison-bush' of Queensland, and the 'Dogwood Poison-bush' of New South Wales; its poisonous properties are said to be more developed when the plant is in fruit. *M. platycarpum* (Dogwood or Sandalwood) is a medium-sized tree of the interior, regarded as a useful

stand-by for sheep in times of drought. It exudes a saccharine substance (manna) of pleasant taste, which is eagerly sought and eaten by the aborigines; they also use its resin as a substitute for pitch in cementing the fibres with which they join the stone heads of their tomahawks to the handle. The pleasantly perfumed timber, of a light walnut colour, is suitable for cabinet-work, having a fine mottled grain. *M. insu'are* (Cockatoo Bush), a coastal shrub, has edible berries of a slightly bitter flavour, much relished by birds, and a hard, durable white wood that has been used for inlaying. *M. debile*, a prostrate undershrub, has small bluish fruits with a bitter taste, which are eaten by the aborigines. *M. tenuifolium* (also known as Dogwood) has a soft, moderately light wood, which dresses well and is straight in the grain.

Myrsinaceae, a large family of trees or shrubs, widely distributed in tropical and subtropical regions. Five genera with 17 species are indigenous to Australia. The flowers are in small clusters; fruit a berry or drupe. *Rapanea variabilis*, found in the eastern States, is a small tree with very variable foliage, the lower (reversion) leaves sharply toothed, those on the upper branches entire. It has a hard, yellowish, durable wood with a grain reminding one somewhat of British oak. *Ardisia jambosa*, a very ornamental tropical tree of 30 feet, bears handsome crimson fruits of the size and shape of a cherry.

Myrtaceae, an important family of trees and shrubs, inhabiting warm and temperate climates, chiefly the former. With 42 genera and 816 species indigenous to Australia, it may be considered the second in size of Australian plant-families; but as it includes the eucalypts it is undoubtedly the first in importance. It comprises two well-marked sections (1) species with fleshy fruits, (2) species whose fruits are dry capsules. The former are widespread in tropical regions, and occur mainly in the warmer areas of Australia; the latter are typically Australian —among them are *Eucalyptus, Angophora, Tristania, Leptospermum, Melaleuca,* and *Callistemon.*

In Myrtaceae the calyx is divided into 5 lobes or teeth or reduced to a narrow border; petals 4-5, imbricate in bud; stamens usually numerous, in one to several series; filaments free, or united into a ring at the base, or in bundles; seeds few or solitary, rarely numerous and perfect; leaves opposite or alternate, simple, entire (rarely toothed), in many genera dotted with small, resinous glands, pellucid or black and superficial. Many species contain aromatic oils or kinos, or furnish useful timbers.

Agonis is an endemic genus of floriferous shrubs or medium-sized trees; *A. flexuosus*, a large shrub or small tree with willow-like leaves and branches, is an easily propagated ornamental shade-tree.

The endemic *Thryptomene* and *Micromyrtus* are chiefly heath-like shrubs with diminutive white, pink, or greenish flowers. A feature of the endemic *Calycothrix* is the elongated, prominently 10-ribbed, calyx-tube, with spreading lobes produced at the summit of their mid-rib into a long hair-like awn. *Rhodomyrtus macrocarpa* (Native Loquat) and *E. psidioides* have hard, tough timbers. The largely tropical *Rhodamnia* has 3 species, all found in eastern Australia; *R. trinervia*, with three-veined leaves characteristic of the genus, has a reddish-brown timber, moderately hard, firm and close-grained. Large trees are invariably hollow, and the timber is inclined to chip when dressed. The wood of *Xanthostemon pachyspermum* is gray to yellowish, tough, strong, and fine-grained.

See ANGOPHORA, BACKHOUSIA, BAECKEA, BARRINGTONIA, CALLISTEMON, CHAMAELAUCIUM, DARWINIA, EUCALYPTUS, EUGENIA, KUNZEA, LEPTOSPERMUM, MELALEUCA, MYRTUS, SYNCARPIA, TRISTANIA.

Myrtle, a name applied to many trees and shrubs of the family Myrtaceae (see ANGOPHORA, BACKHOUSIA, EUGENIA, MELALEUCA, MYRTUS) and, less justifiably, to some outside that family; thus the brush myrtle is a *Trochocarpa*, and *Nothofagus Cunninghami* is sometimes called 'myrtle beech,' or 'myrtle.'

Myrtus, a widespread genus of the family Myrtaceae, consisting of shrubs (rarely trees) with opposite, feather-veined leaves, commonly known as myrtles. All the species indigenous to Australia are endemic. The calyx-tube is bell-shaped, with 4-5 small lobes; petals 4-5; stamens free, numerous in several species; fruit an ovoid or globular berry. Most of the species are ornamental shrubs. *M. acmenioides*, the 'white myrtle' of the eastern scrubs, has a hard, tough, durable timber used by coach-builders.

N

Nail-tailed Wallaby, a genus (*Onychogale*) of the family Macropodidae, distinguished from *Macropus* (in which are comprised the ordinary kangaroos and wallabies) mainly by the presence at the end of the tail of a hard spur or 'nail' of unknown function. (The only other mammal in which such a peculiar structure is found is the lion, in which a similar hard body sometimes occurs.) Three species are known,

Bridled Nail-tailed Wallaby
(*Onychogale frenata*).

all confined to the Australian mainland, frequenting chiefly arid and rocky districts; all are small wallabies with a hairy muzzle, and a long tapering tail covered with short hair. The Bridled Nail-tailed Wallaby (*O. frenata*) occurs in the interior of Victoria, New South Wales, and southern Queensland. The head and body are about 22 inches long, the tail about 18 inches; the soft, thick fur is mainly gray, with white on the chin and chest, pale gray on the belly, and black in the middle of the back of the neck; there is a white stripe across the shoulder, continued along the sides of the back of the neck to near the ear. A second species is the Crescent Nail-tailed Wallaby (*O. lunata*) which now inhabits only a very restricted area in south-western Australia, being considered extinct in central and South Australia. The name is derived from the somewhat crescent-shaped white shoulder-stripe. The third species (*O. unguifera*) is confined to north-western and northern central Australia; it has the spur at the tail-end larger and more conspicuously developed than in the other two species. See MARSUPIALS.

W.A.H.

Nannygai (*Trachichthodes affinis*), a fish of ancient lineage which occurs in moderately deep water on the south-eastern coasts of Australia. It is deep pink in colour, shot with iridescent metallic tints which render it a wonderful object when freshly captured. It has been considered by some authorities to be identical with a fossil genus known as *Hoplopteryx* from the Cretaceous beds of Europe. Four recent species are known from Australian and New Zealand waters, and one from South Africa. Of these, one is the Red Snapper (*T. gerrardi*) of South Australian markets and another the Swallow-tail (*T. lineata*), which, together with the nannygai, are excellent food-fishes. A related genus (*Beryx*) is restricted to deeper water, and is widely distributed. *B. decadactylus* and *B. splendens* were first discovered in the depths surrounding Madeira, where they are known to the fishermen as 'alfonsino;' they have since been trawled in various parts of the Indian and Pacific oceans, and specimens of both species were secured by the Commonwealth trawler *Endeavour* off the coast of Victoria.

A.R.McC.

Nardoo, the aboriginal name for the sporecases (sporocarps) of a small plant, *Marsilea Drummondi*, a mud-loving or aquatic fern with a creeping underground stem. The leaves, when in bud, are curled up as young fronds usually are; when unrolled, they show a leaf-blade orbicular in outline and divided into four segments in the form of a cross, somewhat like the four-leaved clover. The plant has therefore been

Marsilea.

sometimes called 'clover-fern.' Starchy matter is enclosed in a case (sporocarpium), usually borne on a stalk rising from the underground stem. In summer the swamps in which it abounds dry up, and the plants wither away, leaving the fruit-cases on the ground; these are collected by the aborigines, ground between two stones, and made into a paste for use as a food

—but it contains little nutritive matter, is liberally mixed with finely-ground stone, and must be difficult to digest.

Just before the fatal close of the Burke and Wills expedition those explorers were reduced to a diet consisting wholly of nardoo, (as Wills himself calls it); the word belongs to the language of a tribe in the Lake Eyre district. From time to time it has been stated that nardoo is the product of leguminous or other seeds, including grasses; but this was based on the reports of non-botanical travellers more or less ignorant of aboriginal languages. The evidence was exhaustively dealt with by Sir Baldwin Spencer in the *Victorian Naturalist* for 1915; he remarks, 'The name Nardoo is applied to this plant (*Marsilea*) and its product only. There is no real evidence of its ever having been applied by the natives to any other plant or product.'

Nathan, Isaac (1790-1864), born at Canterbury in Kent, England, in 1790; studied Hebrew, German, and Chaldean at Cambridge under Professor Lyon as a preparation for the Jewish priesthood. In his leisure he practised the violin, and showed so great an aptitude for music that his parents allowed him to pursue the study of it under Domenico Corri, an Italian composer and teacher. After eight months he published his first song, 'Infant Love.' About 1813 Douglas Kinnaird introduced him to Lord Byron, who wrote his 'Hebrew Melodies' for Nathan to set to music. The first edition, which appeared in 1815, included several of the favourite airs sung in Jewish religious ceremonies. His intimacy with Lord Byron was interrupted only by the poet's death. For a later edition the 'Melodies' were revised in collaboration with Braham. His debts forced him to leave London for the west of England and Wales, but in 1816 he was persuaded to return and retrieve his fortune on the stage. He appeared at Covent Garden as Henry Bertram in Bishop's opera, 'Guy Mannering,' but his voice was too weak and its compass too small. In 1818 he published a song, 'God Save the Regent,' following it up with a number of operas, pantomimes, and melodramas, some of which were staged at Covent Garden and Drury Lane theatres. In 1823 he published *Musingia Vocalis, an Essay on the History and Theory of Music,* which he dedicated to George IV—at this time he was musical librarian to that King, and instructor to the Princess Charlotte.

On 7 July 1823 he produced at the Haymarket theatre a musical comedy, *Sweethearts and Wives,* which contained two of his most popular songs, 'Why are you wandering here?' and 'I'll not be a maiden forsaken.' At the same theatre on 10 August 1824 a comic opera, *The Alcaid, or the Secrets of Office,* was successfully staged, and in October 1827 a musical farce, *The Illustrious Stranger, or Married and Buried.*

In the musical catalogue of the British Museum no fewer than 12 pages are occupied by his musical compositions and literary works. His best-known literary works are *Fugitive Pieces and Reminiscences of Lord Byron* (1829) and *The Life of Madame Malibran de Beriot* (1836). In 1841, failing to obtain £2000 from the government (on account, he asserted, of work done and money expended in the service of the Crown), he migrated to Australia, where he performed a signal service in developing musical talent and improving music in the churches and choral societies. In 1841 he gave a sacred concert (which included some of his own compositions and works of Handel, Mozart, and Haydn) in St. Mary's cathedral at Sydney; this realized a large sum for the church. On 27 May 1842 he gave a madrigal concert in the hall of what is now the Sydney grammar school. In 1846 he published simultaneously in Sydney and London his *Southern Euphrosyne and Australian Miscellany,* which included examples of aboriginal melodies put into modern rhythm and harmonized as solos, quartets, etc. He also delivered many lectures on music; three given at the Sydney College were published in 1846. On 3 May 1847 Nathan produced at the Victoria Theatre, Sydney, his *Don Juan of Austria,* the first opera written, composed, and produced in Australia. On 15 January 1864 he was killed while alighting from the old Pitt-street horse-tramway.

See Bertie's *Isaac Nathan* (Sydney, 1922).

J.V.C.-B.

Nathan, Sir Matthew, born on 3 January 1862, educated at the Royal Military Academy, Woolwich (senior under-officer and Pollock gold medallist), entered the royal engineers in 1880 (lieutenant, 1880; captain, 1889; major, 1898; brevet lieutenant-colonel, 1907; colonel, 1914; lieutenant-colonel, retired, 1919). Appointed to the fortifications branch of the war office, he designed fortifications at Sierra Leone; served in the Nile expedition in 1885; constructed fortifications at Sierra Leone (1885-7) and in India (1887-90). In 1889 he served in the Lushai expedition; at the war office (1891-1900); was secretary to the colonial defence committee (1895-1900); governor of Sierra Leone (1900-3), Hong Kong (1903-7), and Natal (1907-9). On his return to England he became secretary to the post-office (1909-11), chairman of the board of inland revenue and member of the Pacific cable board (1911-14), and under-secretary to the lord lieutenant of Ireland (1914-16). After the Dublin riots of Easter 1916, he returned to military duty and was employed in the defence of London and as secretary to the pensions department and chairman of the special grants committee. Appointed governor of Queensland, he arrived in Brisbane in December 1920.

During his term of office he travelled through every part of the State. He was chancellor of the university of Queensland; president of the Royal Geographical Society of Australasia (Queensland branch); patron of the Historical Society of Queensland, and of the Brisbane Dickens Fellowship; chairman of the Great Barrier Reef committee, and of the Queensland Place Names committee. In scientific and agricultural matters he was no mere theorist, and his experience in so many avenues of service in different parts of the world was invaluable to Queensland. His departure for England in 1925 was marked by many public expressions of regret. (C.M.G., 1899; K.C.M.G., 1902; G.C.M.G., 1908; P.C. (Ireland) 1914). F.W.S.C.-S.

Native. This word is often prefixed to names properly belonging to European plants. The following list of Australian plants usually so distinguished does not pretend to be exhaustive. The native cherry, native currant, native grape, and native tamarind are dealt with separately.

Native Agrimony	see Acaena.
Native Aster	see Olearia.
Native Bird's-foot Trefoil	see Lotus.
Native Camphor Laurel	see Cinnamomum.
Native Carrot	see Daucus and Geranium.
Native Cascarilla	see Croton.

Native Centaury	see GENTIANACEAE.
Native Cranberry	see LISSANTHE and ASTROLOMA.
Native Dog-rose	see BAUERA.
Native Fuchsia	see EPACRIS, CORREA and EREMOPHILA.
Native Holly	see LOMATIA and OXYLOBIUM.
Native Ivy	see POLYGONACEAE.
Native Kumquat	see EREMOCITRUS.
Native Lavender	see HELICHRYSUM.
Native Lime	see CITRUS.
Native Loquat	see MYRTACEAE.
Native Mulberry	see PIPTURUS and MONIMIACEAE.
Native Nectarine and Peach	see OWENIA.
Native Olive	see OLEACEAE.
Native Pear	see XYLOMELUM.
Native Pepper	see PIPERACEAE.
Native Pomegranate	see CAPPARIS.
Native Poplar	see HOMALANTHUS.
Native Quince	see PETALOSTIGMA.
Native Rose	see BORONIA.
Native Sarsaparilla	see SMILAX.
Native Scrub Lime	see CARISSA.
Native Teak	see FLINDERSIA.
Native Tobacco	see NICOTIANA.
Native Willow	see ACACIA.

Native Bear. See KOALA.

Native Cats, the vernacular name of a genus (*Dasyurus*) of polyprotodont marsupials belonging to the family Dasyuridae, which includes also the banded anteater, pouched mouse, Tasmanian wolf, and Tasmanian devil; these forms are discussed under their own names. Of *Dasyurus* five species are recognized, four being residents of Australia (two of which occur in Tasmania), and the fifth (*D. albopunctatus*) occurring in north-western Papua. They are slender-bodied animals, rather like civets; the fore-limb digits are sub-equal, with sharp-pointed claws, but the first toe of the hind-limb is either very small or altogether absent. The pouch of the female opens vertically downwards, and contains six or eight teats. All the species have white spots distributed over the gray or black surface of the fur. The most widely distributed species is the Common Native Cat (*D. viverrinus*), which occurs in New South Wales, Victoria, South Australia, and Tasmania; its head and body together are about 18 inches long, and the tail about 12 inches. The thick, soft fur is either gray or black, with the usual white spots. The Black-tailed Native Cat (*D. geoffroyi*) is also widely distributed, being found all over the mainland of Australia, except in the extreme north and the eastern coastal districts. It differs from *D. viverrinus* in having the tail black at the end and along the greater part of the under-side, and in the presence of a distinct first toe. The Tiger-cat or Spotted-tailed Native Cat (*D. maculatus*) of southern Queensland, New South Wales, and Victoria, is larger, the head and body being about 25 inches long and the tail about 19 inches. The white spots extend to the tail, and there is a distinct first toe. The North-Australian Native Cat (*D. hallucatus*) is smaller than any of the others, and is confined to the tropics. A sixth species from the Bellenden Ker Range in northern Queensland, was described by Ramsay in 1888, as the Slender Native Cat (*D. gracilis*); it is a small species with a spotted tail, allied to *D. maculatus*, and is apparently a distinct form.

All native cats, so far as is known, have similar habits. All are arboreal, but the spotted-tailed species more completely so than *D. viverrinus*, which is not a very expert climber. Birds and birds' eggs, with an occasional small mammal, are sought after as food; but insects and reptiles are not altogether despised, and species living near the seashore feed largely on dead fish or other animals thrown up by the sea. In districts where they are numerous they do great damage in poultry-runs. See MARSUPIALS and NOXIOUS ANIMALS. W.A.H.

Native Cherry, the popular name of *Exocarpus cupressiformis*, a species of the family Santalaceae. It is a small tree (or large shrub) resembling the European cypress, ranging from Queensland to Western Australia. The diminutive flowers are arranged in clusters on short spikes; the fruit—very few of which mature—is a globular nut seated on a short stalk; this stalk enlarges, turns red, and becomes edible, thus giving rise to the popular

Native Cherry.

fancy that it is a sort of cherry with the stone outside. The leaves are reduced to minute scales. The bark yields a percentage of tannic acid. The close-grained, handsome wood is used for gun-stocks, tool-handles, and furniture, and by the aborigines of the Yarra valley for spear-throwers. Being a parasite on larger trees, it is difficult to propagate.

Native Companion, a very large bird, *Antigone rubicunda*,—often known by the aboriginal name 'brolga'—the sole Australian member of the crane family (Gruidae). Native companions are found throughout northern and eastern Australia, but are rapidly becoming scarce in the settled areas of the south-east and do not occur in Tasmania. They are stately birds of a light gray colour, having long legs, neck, and bill, with a red patch on the back of the head; they feed on lizards, insects, roots

and bulbs. They associate in small flocks and, like other cranes, perform curious dances, spreading the wings and bowing to one another. They are also very powerful fliers, ascending to great heights in the air. The female, without constructing any nest, lays two cream-coloured, slightly spotted eggs on the ground or on a tussock in a swamp.

Native Companion (*length* 42 *in.*).

In northern Queensland the aborigines of the districts which these birds frequent have introduced into corroborees dances imitative of their movements. Such a dance, performed on Dunk Island by aborigines from Princess Charlotte Bay, is described by E. J. Banfield in his *Confessions of a Beachcomber.* W.B.A.

Native Currant, a name commonly applied to *Leptomeria acida,* a species of the family Santalaceae. It is an erect broom-like shrub with angular branches, whose minute, scale-like leaves fall off before the flowers appear. The flowers are small, with a narrow tube and hooded lobes with reflexed tips, crowded in short spikes ½-¾ inch long; fruit a globular, edible berry, very like the common white currant, having a pleasant sub-acid flavour, and used for jellies and preserves. It is found in Victoria, New South Wales, and Queensland.

Native Grape, the popular name for several species of *Vitis* (q.v.) which bear small edible fruits with a remote resemblance in taste and appearance to the grape of commerce. *V. hypoglauca,* a tendril-climber with glossy leaves divided into 5 leaflets, has black fruit as large as small cherries, which might be greatly improved by cultivation; it extends from Victoria to Queensland. If the stem of this vine is cut almost through, and another incision made about three feet higher up, water exudes drop by drop and will soon fill a small cup. J. C. Bidwill (q.v.) saved his life when lost in the bush by procuring water in this fashion.

Native Hens. See RAILS.

Native Tamarind, the popular name for *Diploglottis Cunninghami,* the only species of a genus of the family Sapindaceae, which is endemic in Australia. It is a tall, slender bush tree, ranging from southern Illawarra into Queensland. The leaves have 10-12 leaflets, up to 1 foot long, covered with a velvety coat of rust-coloured hairs; fruit a globular fleshy capsule, the seeds embedded in an amber-coloured pulp (arillus) which has a pleasant, somewhat acid flavour and may be made into a palatable jelly. The wood is white and close-grained.

Naturalists' Societies. See SOCIETIES, LEARNED.

Naturalization. Under an imperial act of 1847, revised and enlarged in 1870, colonial legislatures were empowered to issue certificates of naturalization valid within the limits of their jurisdiction. Under this authority the Australian colonies passed laws providing for the naturalization of duly qualified aliens, the qualifications varying at different times and in different colonies. In Victoria, Western Australia, and Tasmania it was, by the end of the century, competent for any resident alien of good repute to present a memorial (signed by himself and verified upon oath) stating his name, age, birthplace, residence, occupation, and length of residence in the colony, and his desire to settle therein, together with all other grounds on which he sought to obtain the rights of naturalization—whereupon the governor might, if he saw fit, issue a certificate. In New South Wales a residence of five years in the colony, and in South Australia of six months, was required before naturalization could be effected. In Queensland no African or Asiatic alien was competent to apply unless he had resided in the colony three years, was married, and had his wife living with him; if these conditions were satisfied, a certificate might be issued which would entitle the applicant to all the privileges of citizenship except that of entering parliament. Any person presenting a certificate of naturalization obtained in another British possession was not required to show length of residence in any of the colonies, provided that he satisfied the governor of the colony in which he sought naturalization that the certificate had been obtained without fraud, and that he was the person named therein. No Chinese was competent to obtain a certificate of naturalization in New South Wales, Victoria, Queensland, or Western Australia.

In addition to their local laws the colonies were to some extent subject to imperial legislation. An imperial act of 1870 fixed the nationality of the wife by that of the husband, determined the status of minors throughout the Empire, and made provision for the renunciation of British nationality. Moreover it was generally accepted, though never actually determined, that an alien naturalized in Great Britain was naturalized throughout the Empire.

Naturalization was one of the subjects which must obviously, when federation came about, be placed under the jurisdiction of the Commonwealth. This was provided for in the constitution, but the federal parliament did not take action in this regard until 1903. By the

naturalization act of that year, which came into force on 1 January 1904, it was provided that all persons naturalized under state acts before that date were automatically naturalized under the new act. A certificate of naturalization thus carried with it within the limits of the Commonwealth all the rights, privileges and obligations of a natural-born British subject—except that, where by any Commonwealth or state constitution or act a distinction was made between natural-born British subjects and naturalized persons, such distinction should hold good in the case of all persons naturalized under the federal act. The qualifications required of a person applying for naturalization were that he must not be an aboriginal native of Asia, Africa, or the islands of the Pacific (except New Zealand); must intend to settle in the Commonwealth; must either hold a certificate of naturalization obtained in Great Britain or have resided in Australia continuously for two years preceding naturalization; if not already naturalized in Great Britain, must furnish a statutory declaration of name, date and place of birth, occupation, residence, length of residence in Australia and intention to settle therein, together with a certificate (signed by a justice of the peace, postmaster, teacher of a state school, or officer of police) that the applicant was known to him and was of good repute. Provision was also made for naturalization by marriage and by residence with naturalized parents.

In 1917, at the height of the war-fever, the act was amended, mainly to deal with such questions of dual nationality as arose out of the German 'Delbrück' act of 1913. No certificate of naturalization was henceforth to be issued unless the applicant first renounced his own nationality. He was, moreover, required to advertise his intention, in order to afford opportunities for a protest against his naturalization; he must also be able to read and write English. Further, the governor-general was empowered to revoke a certificate of naturalization if he saw fit; previously this had been possible only where the certificate had been obtained by fraud. This drastic provision was modified in 1920, revocation after that date being allowed only for specified reasons and after a judicial inquiry; it was further provided that the wife and the children under age remained British subjects when the husband's certificate was revoked unless the governor-general declared otherwise or they themselves made a declaration of alienage.

At the colonial conference of 1907 (see IMPERIAL CONFERENCES) the British home secretary drew attention to two anomalies regarding naturalization which had for a long time caused 'irritation and inconvenience' both in the dominions and the mother country. In the first place a certificate of naturalization could not be granted to a person in Great Britain if he intended to settle in the dominions, nor did residence in the dominions—or even naturalization in the dominions—serve to shorten the five years' residence qualification required for naturalization in Great Britain. In the second place, naturalization in a dominion was valid only in that dominion; e.g. a person naturalized in Australia was an alien in Great Britain, however responsible his position in the former country might be. (It should be noted, however, that a person so naturalized was 'as a matter of courtesy' given the assistance of British representatives in foreign countries.) To meet this position the home secretary proposed that residence qualifications throughout the Empire should be made uniform and placed on an Imperial basis; e.g. instead of five years' residence in Great Britain five years' residence within the Empire should be required, of which only the last year need be spent in Great Britain. The home secretary also proposed that certificates issued in one part of the Empire should be made valid throughout the Empire, so that an Australian certificate would effect naturalization both in Great Britain and in the other dominions. It was made clear, however, that these proposals, if adopted, would not impair the rights of the dominions to restrict the immigration of British subjects. At the conference of 1911 a compromise was agreed upon to meet dominion susceptibilities; the British government was to pass an act embodying the home secretary's proposals, but this would not bind the dominions unless they adopted it by local legislation. Accordingly a British nationality and status of aliens act was passed in 1914 by the British parliament, Australia coming into line with its nationality act, No. 48 of 1920. The most important provision of this act was the adoption of Part II of the British act, which conferred on any person naturalized under the act the rights of a British subject not only in the Commonwealth but also in Great Britain and in any other parts of the Empire which had also adopted Part II of the British act. It should be noted that under the new act Australian residence qualifications became in some respects more stringent, the former condition of two years' residence in Australia becoming five years' residence within the Empire during the last eight years before application, of which the year immediately preceding application must be spent continuously in Australia. To make our legislation conform better with that of Great Britain, the racial discrimination against the naturalization of natives of Asia, Africa, etc., was dropped. This was not an important amendment, as it did not affect the immigration acts.

To qualify for naturalization under this act and regulations made thereunder (S.R. 1921, No. 22) the applicant must furnish a statutory declaration showing his name, age, birthplace, residence and occupation, residence in Australia continuously during the past year, previous residence within the Empire for at least four years out of the last eight years before the application, and intention to settle in the Empire. He must also furnish current newspapers containing an advertisement of his intention to seek naturalization; certificates of character from three natural-born British subjects, two of whom must be householders, and the third a justice of the peace, postmaster, state-school teacher, or police officer; and satisfactory evidence that he has an adequate knowledge of the English language. Any person may make a statutory declaration with regard to such an applicant, the contents of which will not be disclosed except with the consent of the person making it—except for the purpose of a prosecution for forgery. The governor-general-in-council may without assigning any reason grant or withhold a certificate, as he thinks most conducive to the public good; but no such certificate will be issued until the applicant has produced a certificate from a justice of the high court of Australia, state judge, or magistrate, stating that he has renounced allegiance to the country of which he was a subject at the

time of his application, and that he has taken the necessary oath of allegiance. Residence conditions do not apply to a British-born woman whose marriage to an alien has been dissolved, or to the British-born wife of an alien who during marriage becomes an alien enemy. No fee is charged for the certificate of naturalization. Provision is also made under the act for naturalization by marriage, and by inclusion in a parent's certificate. The governor-general may in his absolute discretion in a special case grant a certificate of naturalization to any minor, whether or not the conditions required by the act have been complied with. Provision is made to enable a person by a declaration of alienage to discard British nationality in favour of a foreign nationality to which he is also subject from birth. The act is administered by the home and territories department, the governor-general being authorized to make any necessary regulations. From 1904 to 30 June 1926 31,971 certificates of naturalization were granted within the Commonwealth.

Status of Aliens.—Aliens and coloured persons, irrespective of nationality, suffer certain disabilities by or under the authority of federal and state legislation. No alien can exercise the federal franchise or hold a seat in the federal parliament; a similar disability exists also, with unimportant modifications, in the various states. No aboriginal native of Australia, Asia (except British India), Africa, or the islands of the Pacific (except New Zealand) may vote at federal elections unless he is enfranchised in respect to the more numerous house of a state parliament. In Victoria no male adult native of China or its dependencies or of any islands in the Chinese seas (unless born of British parents), and no person born of Chinese parents, unless a British subject, may vote at a parliamentary election. In Queensland naturalized Asiatics and Africans are disqualified as voters or members, and Australian aboriginals may not be enrolled as voters. In Western Australia no aboriginal native of Australia, Asia, or Africa, or person of the half-blood, may be registered as an elector for the council (except in respect of a freehold qualification) or for the assembly. In New South Wales, Queensland and Western Australia aliens are debarred from voting at or standing for municipal elections; in Victoria this restriction is limited to male adult natives of China or its dependencies or of any island in the Chinese seas (unless born of British parents) and to alien children of Chinese parents. In the Commonwealth and New South Wales aliens may be appointed to the public service only with the special permission of the governor-general or governor-in-council; in Western Australia they are debarred. In New South Wales, Victoria, and Tasmania restrictions are imposed on aliens in respect to service on juries.

Aliens also suffer disabilities as regards the acquisition of land. In New South Wales an alien must reside a year in the state before being qualified to apply for an original homestead selection, an original purchase-lease, or a settlement-lease, and must become naturalized within five years, otherwise any land so acquired will be forfeited; an alien may become the holder of a homestead farm, a crown lease, a suburban holding or a lease within an irrigation area, but will forfeit his tenure together with all improvements if he fails to become naturalized within three years; alien applicants under the closer settlement act must be subjects of Allied powers—or men who, though subjects of a neutral power, served with the British forces during the war—and must become naturalized within two years of the application. In Queensland no lease of land exceeding five acres in extent may be granted to any alien who has not first obtained in the prescribed manner a certificate that he is able to read and write a passage from dictation in such language as the secretary for public lands directs; by regulation, however, the attorney-general is authorized to grant exemptions in specified cases. An alien must obtain a similar certificate before acquiring a selection or an interest in a selection, and to hold it permanently must apply for naturalization within five years. In South Australia, Asiatic aliens are disqualified from obtaining leases of land in irrigation areas. In Western Australia regulations under the land act prescribe that no lease shall be acquired by an Asiatic or African alien, except of lands open for cultivation which are situated northward of latitude 25° S.

In Queensland, Western Australia, and the Northern Territory there are restrictions on the acquisition or use of miners' rights. In Queensland no Asiatic, African, or Polynesian alien may exercise any privilege under a miner's right except that of alluvial gold-mining on goldfields upon which any Asiatic or African alien was, at the commencement of the act, permitted to mine for gold. In Western Australia no Asiatic or African alien, and no person of Asiatic or African race claiming to be a British subject, may obtain a miner's right without the authority of the minister; no Asiatic or African alien may hold a mining lease. In the Northern Territory a miner's right held by an Asiatic alien entitles him to mine only for gold or tin on alluvial ground; no mining lease may be granted to an Asiatic alien, and no alien is entitled to acquire or hold any lease or any interest therein.

Certain classes of aliens are subjected to other disabilities also in connection with employment and occupation. The best-known example of this results from the definition of 'factory' in the state factory acts, which brings under the regulations any establishment in which one or more Chinese are employed. This was adopted in all the states chiefly as a result of agitation against Chinese 'cheap labour' in the furniture trades. In Queensland, moreover, furniture made by Chinese workmen or on the premises of any Chinese employer must be stamped with the words 'Chinese labour.' In Western Australia no Asiatic may be registered as the owner or occupier of, or be employed in, a factory unless he satisfies the minister that he carried on business in the factory or was employed therein before November 1903.

Among other occupational disabilities may be noted the prohibition in Western Australia and Victoria against aliens holding liquor licences; the refusal to aliens of pilotage exemption certificates under the Commonwealth law, or under the laws of New South Wales, Victoria, and South Australia; and the restrictions on the issue to aliens (especially to Asiatic aliens) of licences connected with the pearling industry in Queensland, Western Australia, and the Northern Territory. Further, aliens not resident in British dominions are prohibited from fishing in Western Australian waters; and the employment of persons of non-European descent in the cultivation of sugar-cane or works connected therewith in Queensland was prohibited by an award of the state court of industrial arbitra-

tion in June 1919, except on farms owned by persons of the same race as the employees. Aliens may not acquire shares in any company incorporated in the Commonwealth without the consent of the Commonwealth treasurer.

Aliens and Asiatics, irrespective of nationality, born outside Australia are ineligible for old-age and invalid pensions; in deference to Indian opinion expressed at intercolonial and imperial conferences, however, the Commonwealth government has agreed to bring down legislation to permit British Indians, otherwise qualified, to enjoy these benefits.

Federal legislation deals specifically with the registration of foreign companies, and to a certain extent restricts the field of their activities and those of companies with foreign shareholders. Thus firms with alien members may not be registered in the Northern Territory without the consent of the administrator; any company in which more than one-third of the shares are held by aliens is prohibited from acquiring any mine or carrying on any mining or metallurgical business without the consent in writing of the federal treasurer; in the Northern Territory mineral-oil licences and leases may not be granted to or held by any company other than a British company in which at least two-thirds of the shares are held by natural-born or naturalized British subjects. In Western Australia mineral-oil licences and leases may be granted only to British companies. Companies under contract with the Commonwealth government for the carriage of mails may employ only white labour in connection with their carriage. Ships in receipt of subsidies or bonuses from foreign governments are debarred from engaging in coasting trade, including trade between the Commonwealth and the Territories, including New Guinea.

In most if not all cases of disability against aliens, treaty-rights are respected.

Nauru, a small coral island situated about 26 miles south of the equator in longitude 166° east, has an area of about 5400 acres, four-fifths of which carry phosphates; the deposits, which have been estimated at 112,000,000 tons and contain from 85 to 88 per cent of tribasic phosphate of lime, occur in a central plateau, bordered by a narrow strip of fertile land whereon live most of the natives. In December 1925 the native population was 1239. Though the island was discovered in 1798 by Captain Fearn in the *Hunter*, and annexed by Germany as one of the Marshall group in 1888, it was not until 1900 that its phosphatic deposits were known to exist. In 1905 the German government granted to a German company a 94 years' concession to exploit the phosphates; in 1906, with the consent of the German government, this concession was sold to a British company (reconstructed as the Pacific Phosphate Company), which worked similar deposits on Ocean Island (British). This company held a monopoly until 1920.

In November 1914 Nauru was occupied by Australian military forces, who remained in control until civil administration was substituted in 1921, the council of the League of Nations having in the previous December formally allotted to the British Empire a 'C' mandate for the island. The terms of this mandate are unusual. Other British mandates of the C class specify the dominion which is to administer them (e.g. the mandate for the former German possessions in New Guinea was conferred on 'His Britannic Majesty to be exercised on his behalf by the Government of the Commonwealth of Australia'), but the mandate for Nauru does not specify the administering government. This was due chiefly to the conflicting interests of Australia and New Zealand in the phosphate-output. In July 1919, 17 months before the formal issue of the mandate, Britain, Australia, and New Zealand had made an agreement (confirmed on behalf of Australia by the Nauru Island agreement act of 1919), which provided for the appointment of an administrator for the first five years by Australia and thereafter as should be decided upon by the three governments concerned. They also agreed to purchase from the Pacific Phosphate Co. its interests in Nauru, as well as its plant on that island and on Ocean Island. In June 1920 this purchase was effected for £3,500,000, of which Britain and Australia contributed £1,470,000 each, and New Zealand £560,000. Control of the phosphates is vested in three British commissioners representing the three governments, each of which has a claim on the annual output (for home consumption only) in the ratio of their respective contributions to the original purchase. The price is fixed by the commissioners 'on a basis which will cover working expenses, cost of management, contribution to administrative expenses, interest of capital, a sinking-fund for the redemption of capital and for other purposes unanimously agreed on by the commissioners and other charges.' When the requirements of the three partners are satisfied, the surplus is sold abroad at market prices. During 1925 215,837 tons of phosphate were exported from Nauru, of which 141,217 tons went to Australia and 74,620 to New Zealand, the total value being £323,755. The deposits are worked by indentured labourers from China (obtained through the Hong Kong government) and a few from the Pacific islands; these are repatriated as their final contracts expire. In December 1925 there were on the island 124 Europeans, 827 Chinese and 10 Kanakas.

The first administrator, appointed by the Commonwealth, took over his duties in June 1921; he exercises administrative, legislative, and judicial powers—subject to the approval of the governor-general of the Commonwealth—and is assisted by an advisory committee of two Europeans and two Nauruans. All expenses of administration are met from local revenue; this amounted in 1924 to £18,200, of which £6689 was paid as royalty by the commissioners. In 1922 international attention was directed to Nauru owing to the apprehension felt by the permanent mandates commission of the League of Nations (which under the terms of the mandate receives an annual report from the Commonwealth) that native interests were being neglected. The Australian high commissioner, however, pointed out to the mandates commission that the authority of the British phosphate commissioners was limited by the administrator's ordinances, which took into account the interests both of the natives and of the indentured labourers. No further objections have been raised.

Naval Defence. The history of the naval defence of Australia comprises three epochs—the purely British epoch, ending with the naval agreement of 1887; the epoch of auxiliary squadrons and subsidies, ending with the de-

fence conference of 1909 (see IMPERIAL CONFERENCES); and the establishment of an Australian squadron as a separate but integral part of the Imperial navy.

First Period.—In the early days of settlement, when there was little commerce to protect, and the utmost danger to be feared was the arrival of one or two enemy frigates in Australian waters to annex lands not yet formally taken over by England, the naval defence of Port Jackson was considered to be amply secured by the presence of a 20-gun ship of 500-600 tons and a small tender mounting six 3-pounders. Even these ships were not always available. Governor Phillip in 1791 declared that the colony ought always to have two ships at its disposal, but this was rather for obtaining supplies from oversea than for protection; in response to his appeal the admiralty sent out H.M.Ss. *Reliance* and *Supply*, and the colonial office shipped the frame of a schooner of 41 tons burthen, which in 1793 was launched in Sydney and named the *Francis*. The first armed vessel belonging to the colony was the *Cumberland*, a 28-ton schooner launched in 1801, but she was armed only 'for pursuing deserters.' For effective defence, reliance could be placed on nothing less than a British warship, and in the middle of the French wars the admiralty had none to spare. Among the visiting warships of those years—besides the *Sirius*, *Reliance*, and *Supply*—were the *Buffalo* (1799-1806), *Porpoise* (1798-1803), *Lady Nelson* (1800 until 1810, when Bligh dismantled her), and a second *Porpoise* (1800-1810). By Macquarie's time the eastern seas were free of French ships, and defence seemed unnecessary; he therefore on 8 March 1810 recommended that no warship be kept on the station, as two small brigs (of 200 and 150 tons respectively) could perform at less expense all the surveying and fetch-and-carrying needed for the colony. Accordingly the colonial office sent out the *Kangaroo* in 1814 and the *Emu* in 1815; it took a year to discover that the *Kangaroo* was unfit for her work, but the *Emu*, which arrived in Port Jackson on 12 March, was condemned before 24 June. In 1821, when Governor Brisbane was about to leave England for Australia, the British cabinet decided—for reasons not given—that in future a warship should be regularly stationed on the coast of New South Wales. From this decision developed the Pacific squadron of the Imperial navy, 'off the coast of New South Wales' being at an early date accepted in a very liberal sense. In 1824 Brisbane urged that 'two vessels should be sent out, commanded by a lieutenant or other naval officer, for the service of the Colony,' with a smaller vessel for Tasmania. Lord Bathurst replied that vessels for such service should be built at Sydney, demurely adding that if Sydney was not capable of building them, Hobart might be asked to do so. For many years no further action was taken in regard to naval defence in the Pacific, the admitted naval supremacy of Britain being considered sufficient protection for her most isolated colonies. In the forties Australian waters were still part of the East Indies station, and the exact date of the creation of the Australian station is to this day a matter of controversy. By some authorities it has been assigned to 1859, when Commodore Loring hoisted his broad pennant as commanding on the Australian station. But an earlier date is probable, since in 1848 the *Shipping Gazette and Sydney General Trade List* twice referred to the admiralty's decision to make Sydney the headquarters of a new station, and there is extant a letter from Colonel Baddeley of the royal engineers addressed on 11 May 1850 to 'Captain Erskine, Senior Naval Officer, Australian Station.'

The Pacific could not always remain tranquil under the shadow of a far distant Britain. So long as potential enemies were equally far away, there was nothing to fear. But in the early fifties relations between Britain and Russia were strained, and Russia had harbours and warships in the northern Pacific; the Australian colonists took alarm, and set about making provision for their own defence. At that time there were in Australian waters six ships of the royal navy—the *Calliope* (26 guns), an old sailing frigate; the *Herald* (8), a brig; the *Electra* (14), a third-class sloop; the *Fantome* (12), a fourth-class sloop; the *Acheron* (5), a small paddle-wheeled steamer; and the *Torch* (9), a similar vessel. This squadron was hardly capable of repelling an attack by such Russian ships as were then believed to be at large in the Pacific—an 80-gun battleship and four 60-gun frigates at Valparaiso, and 14 more frigates at Vladivostock. It was, of course, quite impossible to improvise an adequate defence against vessels of that size and number, but the Sydney authorities did what they could; they sent a gun to South Head (it is still there, near the signal-station), put Lieutenant Fayrer of the *Herald* in command of the pilot-boats at Watson's Bay, and shortly afterwards sent the *Acheron* as guardship to the Heads: 'she was fitted,' says a contemporary account, 'with seven paddle-wheel box boats—two with 12-pound field-pieces, four with 32-pounders, and one with a light 12-pounder.' Her officers were taken from H.M.S. *Calliope*, and her crew was composed of volunteers, with ten experienced seamen to teach them. In May 1854 the departure of four Russian warships from Manila was interpreted as a menace to our trade with China; the authorities were spurred to greater efforts, and in 1855 the *Spitfire*, the first war-vessel built in the colony, was launched at Cuthbert's yard on Port Jackson. She was a vessel of 60 tons, 51 feet on the keel and 61 feet over all, with a draught of 5 ft. 6 in.; her armament consisted of a long 32-pounder gun mounted on a traversing carriage. She was not a formidable craft; but, whatever was expected of her, her actual work was purely peaceful. No Russian ships arrived, and she was first used as a government craft for visiting lighthouses, and later became a coaster carrying produce from the rivers and small ports. In the meantime Victoria, in whose ports ships of the British navy were seldom seen, had taken independent action. Late in 1853 Commander W. N. Lockyer, who had resided in Victoria for some time, was sent to England to superintend the building of an armed steamer for the defence of Port Phillip, and on 31 May 1856 the sloop *Victoria* arrived in Hobson's Bay with Captain W. H. Norman in command. She was a twin-screw steamer of 580 tons, and developed 150 horse-power; she was pierced for six guns, but carried only two 32-pounders and one 68-pounder. Her personnel consisted of 8 officers and 150 men of all ratings. Her actual work was chiefly surveying, but she did good service off the New Zealand coast during the Maori war. In 1856 experiments were made with a new type of harbour-defence craft; two flat-bottomed boats of colonial hardwood were secured together and covered over, so as to afford a working platform 46 feet long by 28 feet

broad; the armament consisted of one smooth-bore 68-pounder gun. This vessel never passed the experimental stage—it simply disappeared, and no record of its service or its breaking-up is to be found.

During the civil war in the United States, the ships of both the Federals and the Confederates scoured the seas, each in search of armed vessels and traders belonging to the other side. Some of these visited Australian ports; the most notorious, the *Shenandoah*, a warship belonging to the Confederate States, put in to Port Phillip and docked at Williamstown. During her stay her captain committed a breach of neutrality by enlisting volunteers for her crew and then clearing out without the usual formalities. It was felt that the presence of an efficient warship would have prevented these occurrences, and in 1867 Sir George Verdon, the Victorian treasurer, while on a visit to England, obtained £100,000 towards the cost of the *Cerberus*, an ironclad for harbour defence purposes, and the gift of the *Nelson*, an old man-of-war which at the time of her launching in 1814 had been the largest ship ever built in England. She was originally a 120-gun three-decker, but after 40 years of peace was cut down to a 72-gun two-decker and given an auxiliary screw. In Port Phillip she became the training-ship for the local naval brigade, but proved very costly; in 1881 she was cut down to a single-decker, and in 1898 was sold to private owners for use as a cold-storage depot-ship; in 1901 she was brought round to Port Jackson and cut in half, one part being converted into a coal-hulk in Neutral Bay (it is now at Launceston in Tasmania), and the other into a lighter, which according to report, is still in use. The *Cerberus*, which carried in her two turrets four 18-ton muzzle-loading rifled guns arrived in 1871, and in her day was the most powerful ship in the southern hemisphere. She reposed peacefully off Williamstown for more than a generation, and when defence became a more live subject was declared to be hopelessly obsolete and her guns of very little use.

In 1867 Robert Rutter, a civil engineer of Sydney, proposed to build a floating battery shaped like a life-buoy, with a displacement of 5620 tons; her armament was to consist of 24 100-pounder guns which she was to discharge while revolving on her axis, thus keeping up a continuous broadside.

In 1869 a definite proposal was made by the admiralty to establish a permanent Australian naval force, the colonies to pay half the cost and the upkeep. This proposal fell through. In 1872 the first two of five armed schooners were built in Sydney to the admiralty's order; their original names, *Nea* and *Eglantine*, taken from two Sydney ladies, were changed by a shocked admiralty official to *Alacrity* and *Beagle*. The other three, *Conflict*, *Renard*, and *Sandfly*, were launched shortly afterwards. These schooners were not intended for defence, but for the control of Queensland labour-recruiting in the Pacific; a decade later they were sold, the *Alacrity* and *Conflict* in 1882, the *Beagle*, *Renard*, and *Sandfly* in 1883. In 1876 Lord Carnarvon, then secretary for the colonies, selected Sir William Jervois (q.v.) and Colonel Scratchley (q.v.) to discuss with the colonial governments a policy of naval defence. The notion that any government except the British should be concerned with naval matters does not seem to have occurred to anyone in previous years. In 1878 Scratchley published his reports. His naval proposals were based on the policy of leaving offensive action at sea entirely to the Australian squadron of the royal navy; but he recommended that the wealthier colonies should provide a few swift ironclad gunboats to protect trade, and a few torpedo-boats or launches to act in conjunction with shore batteries erected on the principal harbours and estuaries. He further recommended that all locally provided vessels should be manned by locally established naval brigades, and that all floating defences should be strictly under the control of the officer commanding the Australian squadron. Political changes in the colonies killed this scheme, but in 1881, at an inter-colonial conference, the premier of South Australia revived the proposals of 1869. The four eastern colonies rejected them, on the ground that, as large imperial interests were involved, the maintenance of sea-defences was entirely within the province of the British government; land-defences, they admitted, should be a charge on the colonial governments. Each colony now proceeded independently. In New South Wales a naval brigade had already been formed, mainly to reinforce the squadron in times of emergency, and in 1881 the admiralty gave it the screw-corvette *Wolverene* as a training-ship. Besides the *Victoria*, *Nelson*, and *Cerberus*, the naval defences of Victoria in 1885 included the *Childers*, a first-class torpedo-boat, two second-class torpedo-boats, and four harbour trust dredgers armed with old guns; Queensland in 1884 commissioned two gunboats (the *Gayundah* and *Paluma*) and a torpedo-boat (the *Mosquito*); South Australia in the same year obtained the small, but heavily armed, cruiser *Protector*, specially designed for driving raiders out of the South Australian gulfs into the open ocean. The vessels had scarcely reached Australian waters when Britain and Russia found themselves on the verge of war through the capture by Russian troops of Penjdeh in Afghanistan. Luckily the British squadron in the western Pacific was at the same moment strengthened by the arrival of the armoured cruiser *Nelson*, and still more by the appointment to command of Admiral Sir George Tryon (q.v.), whose energy was at once shown by his requisitioning of two mail-steamers as auxiliary cruisers.

The independent efforts of the four colonies, narrated above, had not satisfied the imperial authorities, who held that Australia should take over a share of the responsibility for defence at sea, as distinguished from that of harbours and coasts. Tryon had therefore been instructed to confer with the colonial premiers, and during his stay laid down the principle that personal service was better than any amount of subsidy—a declaration which in after years became the watchword of the advocates of a really Australian squadron. More immediate results of Tryon's work became evident at the colonial conference of 1887 (see IMPERIAL CONFERENCES), where it was decided that the existing British squadron in Australian waters should be supplemented by an 'auxiliary squadron' of five fast third-class cruisers and two torpedo-gunboats. Beyond certain limits these vessels could be employed only by permission of the colonial governments, but within them they were to be controlled by the officer commanding the Australian squadron, which was to be maintained at its normal strength. They were to be constructed at British expense, and were to revert to Britain whenever the agreement terminated;

the colonies concerned were to pay 5 per cent on their prime cost and £91,000 a year towards their maintenance; three cruisers and a gunboat were to be in permanent commission and the remainder kept in reserve in Australian ports. Though this agreement did not realize Tryon's ideal, it was at any rate the beginning of a definite Australian enterprise, and a locally manned and locally controlled squadron was out of the question so long as Australia had no central government. The agreement—which was for ten years, subject to two years' notice of termination on either side—was ratified by most of the colonies during 1888 and by Queensland in 1891. When the ships arrived, they became a working portion of the Australian squadron.

Second Period.—In 1893, owing to financial stress, all-round reductions were made in defence expenditure. Victoria and Queensland put their warships out of commission and reduced their naval establishments; South Australia placed the *Protector* in reserve; New South Wales, favoured by the presence of the squadron, declined to replace the *Wolverene* (which had been broken up in 1889), and left her naval brigade to struggle along as best it could. For the next six years little advance was made; but in the winter of 1899 the naval commandants of New South Wales, Queensland, South Australia, and Tasmania, and the secretary of the Victorian defence department drew up a report of great importance. Avowedly basing their recommendations on the high value which Admiral Tryon had placed on personal service, they asked that the existing local forces should be made 'efficient and available for service in vessels of war.' They complained that little or nothing had been done towards the drilling and training of Australian seamen, as the vessels in reserve of the auxiliary squadron had always been laid up in Sydney and no attempt had been made to utilize them for training. They pointed out that 'the present policy, namely that of payment in specie in return for naval defence furnished *in toto* by the mother country, makes for no advance whatever.' Not only should the several naval brigades be amalgamated into a single federal force, but the admiralty should provide ships of a type which would be effective for service in time of war, and in which the local forces could be drilled in time of peace. They calculated that the actual expenditure on local naval forces, *plus* the contribution under the 1887 scheme, would maintain five second-class cruisers and a reserve sufficient both to man them in time of war and to make up wastage in the Imperial squadron.

During the 'Boxer' war in China three vessels of the auxiliary squadron were lent to the admiralty for service there; Victoria and New South Wales also sent their naval brigades for land service, and South Australia contributed the *Protector* (see CHINA NAVAL CONTINGENT). When the vessels so lent returned, the whole naval situation became a subject of debate. On the one hand objections were raised to the use of Australian vessels and men in fighting which did not directly concern Australia. On the other hand the limitations under which British admirals controlled the auxiliary squadron had for some time disturbed both the admirals and the admiralty. Commanders did not wish to co-operate with a squadron over which they had not full control, and the admiralty, at last finding it necessary to take the colonies seriously, began to develop its strategic creed in a series of propositions for their enlightenment—that naval defence cannot be a matter of merely local interest; that it consists, on the contrary, of a general offensive to destroy enemy ships wherever they may be; and that this conception necessitates a single navy under one control. These principles influenced the Australian delegates at the colonial conference of 1902. Captain W. R. Creswell, the naval commandant of Queensland, had just before that event revived the contentions put forward by the commandants in 1899, and suggested that the Commonwealth should provide a squadron of five cruisers—one to be built every second year—for use as training-ships for the local forces, a training-ship for boys, and a navigation school for naval reservists. The cruisers would be manned in peace time by reduced crews and raised to war strength from the naval reserve; they would form a reserve for the Imperial squadron in Australian waters, capable of operating wherever required. This report was freely quoted and discussed at the conference. The admiralty's contribution was a memorandum in which the principles already stated were set forth, and the first lord personally stressed the need of a single controlling naval authority. In order to make some concession to the Tryon principle of personal service, he suggested that one, if not two, cruisers of the Australian squadron should be manned exclusively by Australians under the command of Imperial officers, and that these ships should be interchanged occasionally with ships of other squadrons. He also suggested the formation of branches of the royal naval reserve, and insisted on the futility of confining the activity of the auxiliary squadron within narrow geographical limits—they should be available for service anywhere in the eastern seas.

The outcome of the conference was a scheme giving effect to these views. The old distinction between ships of the royal navy provided by the Imperial government and the ships paid for by Australia was abolished. The admiralty bound itself to maintain a squadron of definite strength based on Australian ports but operating wherever required by the naval exigencies of the occasion, The Commonwealth agreed to pay five-twelfths of the total cost annually up to a maximum of £200,000, New Zealand paying one-twelfth. Three drill ships, and one other, were to be manned as far as possible by Australians and New Zealanders, and officered by R.N. and R.N.R. officers. Eight navy cadetships were given annually to Australia and two to New Zealand, and branches of the royal naval reserve were to be established. In London the novelty of this scheme was not realized, and it was looked upon as merely an extension of the 1887 arrangement. But in point of fact, though probably without knowing it, Lord Selbourne had abolished the idea of hirer and letter, which gave Australia a definite feeling of practical ownership, and had substituted that of subsidy, against which Australians had protested in 1887 and at all times since, when the question arose. In some sense the auxiliary squadron had been to the bulk of Australians a personal possession, about the use of which they had often been jealous and selfish; the new squadron was not theirs at all. In spite of a distinct gain in the matter of personal service, public opinion resented what it considered a distinct loss. In the Commonwealth parliament George Reid, and later Alfred Deakin, made public their objections to the subsidy, and popular feeling ran so high that at the elections of 1903 ministerial candidates were seriously hampered (and in

some cases defeated) because of their adherence to the new agreement.

One good thing came of all this agitation: the naval brigades, so long neglected, gained some prominence. Before federation they were probably valueless as active forces; but they proved invaluable to Australia in other ways; they maintained, through long periods of neglect and discouragement, the belief in personal service, and they provided, when public dissatisfaction with the 1902 scheme became resistless, the germ of a constructive counter-proposal.

The naval forces in the several States, and all persons whose employment was connected therewith, were transferred to the Commonwealth on 1 March 1901, but until 28 February 1904 were administered under the State acts and regulations. On 1 March 1904 the Commonwealth Defence Act of 1903 came into force, and an amending act of the same year established a naval board of administration with a director of naval forces as its executive officer. On 12 January 1905 the new board came into existence, and Captain William Rooke Creswell, who had commanded the naval forces since 27 February 1904, was appointed director. The ships taken over from the States were in poor condition and had not even nucleus crews—the natural result of ten years' unsystematized economies. They were:—

from Victoria:
Cerberus, twin-screw armour-plated turret-ship, 4 guns, 3480 tons, 1660 h.p.
Countess of Hopetoun, first-class torpedo-boat
Childers, first-class torpedo-boat
Lonsdale, *Nepean* } second-class torpedo-boats

from Queensland:
Gayundah, *Paluma* } twin-screw gunboats, each 2 guns, 360 tons, 400 h.p.
Mosquito, second-class torpedo-boat
Midge, torpedo-launch

from South Australia:
Protector, cruiser, 6 guns, 920 tons, 1641 h.p. and a second-class torpedo-boat

In 1905 Creswell put forward a scheme for a local squadron of three 3000-ton 'cruiser-destroyers,' 16 destroyers, five first-class and eight second-class torpedo-boats, to be constructed (in Australia as far as possible) within five years; the scheme also included provision for the eventual manufacture of munitions and ordnance in Australia, and the assumption by the Australian forces of responsibility for local defence, the squadron becoming an integral part of the Imperial navy. These proposals stirred the Commonwealth government to ask the British committee of Imperial defence to prepare a general scheme of Australian defence, and early in 1906 Creswell was sent to England to study naval developments, especially as they affected destroyer and torpedo-boat work. During his absence the report of the committee of Imperial defence reached Australia, and was found to include a condemnation in general terms of his scheme, mainly on the ground that a destroyer force was not at the moment needed, and would be supplied by the admiralty when it was. His fellow-commandants took the opportunity of his return to Melbourne to contest this condemnation, and put forward a modified scheme comprising four ocean-going destroyers, 16 coastal destroyers, and four first-class torpedo-boats. Under admiralty influence Deakin rejected this proposal; but in 1907 his persistent advocacy of some form of local squadron or flotilla forced the admiralty to make some concessions, and he brought back from the Imperial conference of that year a new scheme for a flotilla of nine first-class torpedo-boats and six submarines. Local expert opinion at once condemned this proposal, largely because the submarines of those days, while capable of useful work in the comparatively shallow seas off western Europe, were quite unsuited to operations in the deep channels, rapid currents, and storm-ridden areas of Bass Strait and the Tasman Sea. This scheme, therefore, also fell through; but Deakin put aside from surplus revenue an amount sufficient to build several torpedo-boats whenever parliament should give him permission. Fisher, succeeding him in April 1910, adopted a scheme for 19 destroyers (practically that of the commandants in 1906) and used Deakin's savings to build three of them at once.

Third Period.—Early in 1909 the whole Empire was alarmed by the speeding up of warship construction in Germany and by speeches made on the subject by the British foreign secretary, Sir Edward Grey, and the first lord of the admiralty, Reginald McKenna. Enthusiasts in Sydney initiated a movement for presenting to the mother country a battleship of the then new 'Dreadnought' type; the premier of New Zealand, Sir Joseph Ward, with still greater enthusiasm offered two. About £100,000—manifestly a quite inadequate sum—was raised by private contributions in Sydney, and after some manoeuvring the premiers of New South Wales and Victoria were induced to offer a 'Dreadnought' jointly, if the Commonwealth refused to do so. Andrew Fisher, then prime minister, preferred to spend money on a local squadron, but suggested an Imperial conference on naval affairs, and offered to place all Australian warships at the disposal of the admiralty automatically whenever war might seem imminent. At the critical moment Fisher was ousted from office by a coalition between the followers of Deakin and of Joseph Cook, and the new ministry sent to the naval conference a delegate (Colonel Foxton, q.v.) who was instructed to offer a 'Dreadnought' or any other form of help that the coming conference might recommend. The conference met on 28 July, discussed naval matters on 3, 5, and 6 August, and in the end recommended (as far as Australia was concerned) that the whole system of Pacific defence should be remodelled. A Pacific fleet was to be constituted of three units, one specially attached to the Australian station, one to the East Indies, and one to the China station; the last-mentioned would take charge of New Zealand. Each unit was to consist of a large battle-cruiser (*Indomitable* type), three second-class cruisers (*Bristol* type), six destroyers ('River' class), and three submarines ('C' class). The battle-cruiser offered by New Zealand would be the flagship of the China unit, and that offered by Australia of the Australian unit; the units would meet periodically to carry out fleet exercises. The East Indies and China units would remain under direct admiralty control, but the Australian unit would be paid for, controlled, and eventually manned entirely by Australians, great care being taken to ensure the maintenance in Australian ships of British naval standards. This acknowledgment of the long-favoured Tryon principle of personal service as against subsidies was heartily welcomed in Australia; the 'unit' scheme was developed and improved in details by the Imperial conference of 1911, and, until the war of 1914-18 'scrapped' all previous naval arrangements, remained the Australian ideal of naval defence in the Pacific.

The Commonwealth's efforts were now directed

single-heartedly towards the completion of its unit and the necessary accessories. In September 1910 two destroyers, the *Parramatta* and *Yarra* (ordered by Fisher in 1908), reached Australia; a third, the *Warrego*, was shipped out in parts, put together at Cockatoo Island dockyard, and commissioned on 1 June 1912. The battle-cruiser *Australia* and the light cruisers *Melbourne* and *Sydney* arrived in 1913, and the two submarines in 1914. A naval college for training officers was established temporarily at Geelong in Victoria, and moved to its permanent quarters at Jervis Bay in New South Wales in 1915. The Commonwealth government in 1911 purchased from New South Wales the reformatory ship *Sobraon*; she was remodelled and placed in commission as the *Tingira* for the training of boys for the personnel of the Australian navy. The age of entry is from 14½ to 16½ years and the boys must engage to serve until they reach the age of 30. Training lasts one year, and trainees are then drafted to a sea-going warship of the fleet. (At the time of launching, 1866, the *Sobraon* was the largest vessel afloat, length 320 feet, beam 38 feet.) In 1910 the Fisher ministry invited Admiral Sir R. G. Henderson to report on the location of naval bases and training schools, and requested that he would make any other suggestions he chose; his report therefore, while dealing adequately with the subjects at first suggested, expanded into an elaborate memorandum covering the whole development of a purely Australian navy for the next 20 years. Entirely neglecting the conception of units—and basing his estimates on the proportion borne by the trade and population of Australia to that of Great Britain, he planned a fleet of 52 ships, with a personnel of 14,844, and an organization into squadrons and flotillas, for which 16 bases and sub-bases would be required. This fleet was to be acquired during four 'eras,' the first being of seven years (1911-18), the other three of five years each. At the end of the first era the fleet would consist of 23 ships with 4384 men. The report was handed in early in March 1911, but was not favourably received. The minister of defence (Senator G. F. Pearce) accepted its immediate recommendations—'it is quite possible,' he said, 'to proceed a certain distance along the route marked out without committing ourselves to the whole scheme;' but the prime minister (Andrew Fisher) declared that it could 'not in any way serve as Australia's share in the defence of the Empire. Sir Reginald Henderson has only concerned himself with the local Australian aspect of defence, and not gone into matters affecting the Empire generally.' Work was begun on some of the proposed bases, and the naval administration was reorganized as Henderson suggested; the ambitious 'Australian navy' proposals were soon forgotten; certain recommendations regarding the size of additional ships were accepted in principle, but the scheme was in abeyance at the outbreak of war in August 1914.

Meanwhile the unit scheme had been transformed almost out of existence. Persistent attempts were made from 1912 onwards to persuade Australia and New Zealand to leave their battle-cruisers in European waters, and New Zealand agreed. Ships of a less important type were sent to the China and East Indies units as flagships, and the *Australia* (see AUSTRALIA, H.M.A.S.) was thus left the only ship of her type in Eastern Waters. This naturally made the 'Pacific fleet' an absurdity, and in March 1914 Winston Churchill, then first lord, announced that battle-cruisers were not needed in the Pacific and should be employed nearer home. Senator E. D. Millen, then minister for defence in the Commonwealth ministry (Joseph Cook's), challenged him at once, declared that the admiralty had broken the agreement of 1909-11 without giving Australia any notice, and demanded another naval conference. While negotiations in this connection were still in progress, war came.

The Australian navy as it fought in the war, consisted of the following vessels:—

	tons.	knots.	guns, etc.
Battle-cruiser:			
Australia	19,200	26	8 12-in.
Light cruisers:			
Melbourne, *Sydney*, *Brisbane*	5400	26	8 6-in.
Encounter	5900	21	11 6-in.
Small cruisers:			
Pioneer	2200	17½	8 4-in.
Psyche	2100	17½	6 4-in.
Destroyers:			
Parramatta, *Yarra*, *Warrego*, *Huon*, *Swan*, *Torrens*	700	27	1 4-in. 3 18-in torpedo-tubes
Submarines:			
AE 1 and *AE 2*	800	16	4 torpedo-tubes
Gunboats:			
Protector	920	14	3 4-in.
Gayundah	360	10½	1 4.7-in.
Sloops:			
Fantome	1000		2 4-in.
Una	980		4 4-in.

The Australian submarine depot-ship *Platypus* and the oil-tanker *Kurumba* were used by the admiralty in European waters during the war. All the other ships were manned by Australians, but in the larger ships there was a considerable number of officers and men who had been borrowed from the royal navy before the war broke out. The *Encounter* had been lent for service while the *Brisbane* was building, and the *Pioneer* was a gift from the Imperial government; at the request of the admiralty the *Psyche* and the *Fantome* were manned by the R.A.N. in 1915. The *Una* was captured by the R.A.N. at Rabaul in 1914. At the close of the war the Australian navy was employing the following personnel:—

Royal Australian navy (sea-going) 325 officers, 4647 men (including those lent by the R.N.).
Royal Australian naval brigade 151 officers (69 mobilized), 4341 men (2099 mobilized).

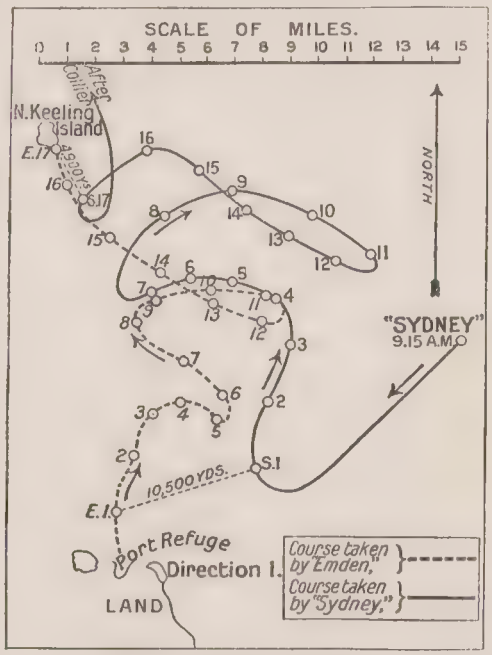
Although it had been placed under the imperial command at the outbreak of war, a technical misunderstanding postponed the transfer of the fleet to British control till 10 August 1914. Before the actual outbreak steps had been taken for the defence of Australia and for the prosecution of war in the Pacific. In the early days of August the *Australia* and *Sydney* with the destroyer flotilla were on their way to the Bismarck Archipelago, hoping to find the *Emden* and *Konigsberg* of the German Pacific squadron. Entering Blanche Bay on the night of 11 August, they found that the cruisers had left. Admiral Patey (q.v.), surmising that they were proceeding to the Atlantic, asked to be allowed to give chase, but was ordered back to escort the military expeditions which were being sent from New Zealand and Australia to occupy Samoa, the Bismarcks, and New Guinea. About the middle of September the *Emden* appeared off Bengal, and German cruisers off Samoa. The *Australia* was sent to Fiji, and the *Melbourne* and *Sydney* to Port Jackson to escort

troops to Egypt. After Coronel the *Australia* was despatched to the western coast of Mexico, to join other ships and prevent the Germans from making a break back to Canadian waters; on the way she captured the German supply-ship *Elenore Wormann*. She was then called to England, to be flagship of the second battle-cruiser squadron in the North Sea. Owing to damage sustained in a collision she missed Jutland (see AUSTRALIA, H.M.A.S.).

Towards the end of October the *Melbourne* and *Sydney*, together with a British and a Japanese warship, were convoying 30,000 troops to Egypt. On the morning of 9 November signals were received from Cocos Island that a strange warship was approaching. The *Melbourne* immediately set off, but her captain, remembering that he was responsible for the convoy, signalled the *Sydney* to proceed. The enemy proved to be the *Emden*. She had in the meantime landed a party of about 40 men to wreck the wireless and cable station on Direction Island. As the *Sydney* approached, the *Emden* steamed out to do battle at closer quarters. The *Sydney* had the heavier guns, the longer range, and the greater speed. But whereas the admiralty information was that the *Emden* could do no great damage at five miles, it turned out that, through the German system of elevating the guns, she could fire effectively at six or over. The *Sydney* therefore met with a surprise, and received some initial injury. Captain Glossop, seeking to use his guns at their most effective rather than their farthest range, had brought his ship within reach of the enemy, and in 15 minutes the *Sydney* received hits from 15 shells, though only five of them burst. Her range-finder was wrecked and its operator killed, as were also some men among the gun-crews. On discovering his mistake as to the *Emden's* range, Glossop steamed out farther, and while the enemy sought to come in closer, he manoeuvred so as to get her at his mercy, while he himself sustained no further damage. The courses taken by the two ships are shown in the accompanying diagram. The *Sydney's* shells worked such havoc that the *Emden* retained neither the speed nor the firing-power necessary for her purposes, and Glossop brought his vessel within three miles (see position 7) and there fired a torpedo, though without result. Eventually von Müller decided to run the *Emden* ashore on Keeling Island. Assured that she was securely aground, Glossop then went after her attendant collier, the *Buresk*, which he overtook as the Germans were sinking her. After taking off her crew, he completed the sinking with his guns, and then returned to the *Emden*. The German flag was still flying, and, as he could get no answer to his call for surrender, he proceeded to demolish her from a distance of two miles. After two salvos the flag was lowered and a white sheet displayed. Uncertain of the situation on Direction Island, Glossop lay on and off all night, visited the cable-station in the morning, and, finding that the German landing-party had escaped the evening before in a small schooner (the *Ayesha*) which they had seized, he returned to Keeling Island, where he found the *Emden* riddled with shots, littered with dead, and with 70 men wounded and practically untended. These, and 110 other prisoners, he took off to the *Sydney*, and then made for Colombo.

[Meanwhile von Mücke, the commander of the German landing-party, had made for the Dutch East Indies in the *Ayesha*. From Sumatra he and his men were picked up by a German coasting steamer and carried across the Indian Ocean. Slipping into the Red Sea, they landed on the Arabian coast, reached the Mecca railway, and thence made their way back to Germany via Constantinople. Their romantic adventure does great credit to their spirit and resource.]

From Colombo the *Sydney* proceeded to Egypt, and thence with the *Melbourne* to the West Indies, where for 18 months both cruisers formed part of the patrol between Halifax and Panama and down the east coast of South America. Of the remaining ships, the *Pioneer*, a relic of pre-Commonwealth days, was sent to East Africa, and was present at the blockade and destruction of the *Konigsberg*. In the midst of this activity the two submarines AE1 and AE2 were lost, the former somewhere near Blanche Bay, the latter in the Dardanelles, whither she had been sent at the end of December 1914. On 25 April 1915 she was ordered to try to force the straits, and was the first British ship so to do, but received such damage that her crew were compelled to sink her and surrender. By this time plots were being formed by the Germans in San Francisco to stir up revolt in India, and Australia was asked to send all available help. The three destroyers, *Parramatta*, *Yarra*, and *Warrego*, the old cruiser *Encounter*, the *Psyche*, the *Una*, and the *Fantome*, were despatched to the China station. The *Encounter* was soon sent back to Australia and the *Una* to the Bismarcks, and after a year the three destroyers were relieved by three others, the *Huon*, *Swan*, and *Torrens* (which had been built in Australia). The newly



The pairs of numbers represent the positions of the two ships relatively to each other at various stages. Thus 1, 2, etc. on the course of the *Emden* correspond to 1, 2, etc. on the course of the *Sydney*. The dotted line E.1----S.1 indicates the beginning of the action at a range too favourable to the *Emden*. The stage at which the *Sydney* attempted unsuccessfully to torpedo the *Emden* is indicated by the figure 7 on the respective courses, the range at the time being 5500 yards.

commissioned *Brisbane* left for Malta. In 1917 the six destroyers were ordered to the Mediterranean to take part in the anti-submarine campaign, while the *Encounter*, the *Protector*, the 'quite obsolete' *Gayundah*, and the 'prehistoric gunboat' *Countess of Hopetoun* were left to guard the Australian coasts.

During 1917 the German raider *Wolf* laid mine-fields off the Cape of Good Hope, Bombay, Cape Howe, Cook Strait, and North Cape in New Zealand, and several ships were sunk. The *Wolf's* exploits brought the *Brisbane* back from Malta to Australia. After searching the Indian Ocean with the aid of a sea-plane, she was sent to patrol New Guinea waters. A second raider, the *Seeadler*, a converted merchantman, visited the Pacific in 1917, but did little damage before stranding on an island in the Society group. Her commander and some of the crew made an unlucky dash to Fiji; the rest made for South America, where they were interned. These raiders caused a hastily improvised but continually improved system of local patrols to be organized by Australia and maintained up to the end of hostilities. In the meantime the bigger ships, after leaving the Atlantic patrol in 1916, were employed in the North Sea to shepherd convoys of merchantmen across to Norway. The *Sydney* in the course of her work scouted for submarines and had an encounter with a zeppelin. The destroyer flotilla worked with British flotillas at the mouth of the Adriatic, often aiding Italian transports in difficulties. At the close of the war the Australian ships were thus distributed:—In British waters: *Australia, Melbourne, Sydney, Platypus,* and *Kurumba*; in the Mediterranean: *Brisbane* and six destroyers; patrolling Australian trade-routes: *Encounter* and *Fantome*; patrolling Bismarck Archipelago: *Una*; in minor patrols off Torres Straits, Fremantle, Spencer Gulf, Bass Strait, and north-western Australia: *Protector, Countess of Hopetoun,* three small steamers, and two ketches.

Practically all the shore work during the war, as well as all manner of local patrols and most of the mine-sweeping, was entrusted to the royal Australian naval brigade (which in pre-war times was the reserve). It was responsible from 3 August 1914 to 21 November 1918, for the examination service at the ports of the six State capitals; for the port war-signal stations at the same ports and at Albany up to 2 December 1918; for harbour patrols at the nine defended ports; for dock defences (guards, booms, and net defences); for mine-sweeping off the ports; and for an immense amount of naval intelligence work. In 1916 it took over the guarding of wireless-stations, and in 1917 the guarding of wharves and ships and the examination of all cargo and baggage to prevent internal explosives from being smuggled in. It also supplied crews for coastal patrol vessels, officers and ratings for R.A.N., guns' crews and signallers for defensively armed merchant vessels, telegraphists for wireless service, and about 300 volunteers for the A.I.F. Two detachments—the naval contingent and the royal Australian naval bridging train—went overseas, the former aiding in the seizure of the German Pacific islands, and the latter serving with the ninth British corps at Suvla and afterwards in Egypt. The contingent was called for on 9 August 1914, mobilized by the 15th, and sailed for Rabaul on the 17th. After a few weeks' training on an island off the coast of Queensland, the 500 men joined a military expedition and sailed for Blanche Bay, where they captured the German wireless-station, while the battalion was sent on to capture Rabaul. The bridging train was raised in February 1915 for service in Flanders, but in July was sent to the Dardanelles, where it reorganized the water-supply, created an excellent harbour, and salved many wrecks. After the evacuation it was detailed for service on the southern portion of the Suez Canal in engineering and traffic duties and the construction and control of pumping machinery and filter-beds. In 1916 it was detailed to make a landing at El Arish, build jetties, and establish communications. With the advance into Palestine the need of military control on the canal ceased, and the train was disbanded. Some members joined the invading contingent, but most returned to Australia for further service in the R.A.N.

The Washington disarmament treaties of 1922 made a great change in naval defence schemes, and all warship building and naval base construction were suspended. The fleet personnel was reduced from 4843 in 1921 to 3500 in 1923, and ships in commission from 25 to 13. On 12 April 1924 H.M.A.S. *Australia* was sunk in accordance with the provisions of the Washington treaty. After the Imperial conference, the defence equipment bill was brought before the house on 27 March 1924 and received assent on 27 August 1924. It proposed the construction of two 10,000-ton cruisers—the maximum size at present allowed for new construction under the Washington conference—two ocean-going submarines, and a seaplane carrier. The cruisers are expected to be ready by 1928, and the submarines, now being built in England, in 1927. The seaplane carrier is to be built at Cockatoo Island dockyard, Sydney, by the Commonwealth shipping board. In addition the Commonwealth government is subsidizing the New South Wales government in the construction of a large floating dock which will be available for naval use in times of war or emergency. From July 1908 to June 1924 the expenditure on Commonwealth naval construction amounted to £7,171,583.

SHIPS OF THE ROYAL AUSTRALIAN NAVY, JUNE 1925.

Vessel.	Description.	Displacement.	Power.
		tons.	h.p.
Adelaide	Cruiser	5,500	25,000
Anzac	Flotilla leader	1,660	36,000
Brisbane	Cruiser	5,400	25,000

The *Moresby* (formerly the *Silvio*) is on loan from the royal navy for use as a surveying ship.

STRENGTH OF NAVAL FORCES (PERMANENT AND RESERVES), MAY 1925.

Description of Force.	Numbers Borne.		
	In Training.	Officers.	Men.
Royal Australian Navy (sea-going)	.....	406	4,219
Cadet midshipmen undergoing training at R.A.N. College	49	.....	.....
Boys undergoing training on H.M.A.S. *Tingira*	256	.....	.....
Royal Australian Naval Reserve (sea-going)	.....	58	.....
Royal Australian Fleet Reserve	.....	.....	131
Royal Australian Naval Reserve	.....	145	5,804
Royal Australian Naval Volunteer Reserve	.....	3	31

The following table shows the naval defence expenditure in various years from 1901-2 to 1924-5 in pounds sterling:—

Year.	Under Ordinary Votes and Appropriations.	Total. (*a*)
	£	£
1901–2	178,819	178,819
1906–7	255,120	256,066
1911–2	461,546	1,634,466
1916–7	1,510,542	6,641,249
1921–2 (*b*)	2,375,965	3,212,736
1922–3 (*b*)	2,124,491	2,575,131
1923–4 (*b*)	2,084,420	2,279,310
1924–5 (*b*)	2,086,021	2,386,234

(*a*) During the war years, and subsequently, war expenditure including that on works, is comprised in the total.
(*b*) Not including war gratuity.

After the war Admiral Jellicoe was invited to examine and report on the naval defence of the Commonwealth. Arriving in May 1919, he presented his scheme in August. It dealt largely with the far-Eastern problem, and his suggestions as to the size and character of the Australian fleet were made with a view to ensure effective co-operation with the royal navy in the event of any necessity arising. He proposed the following unit:—

1 New battle-cruiser
1 „ „ „ (*Australia* type)
4 Light cruisers in commission
4 „ „ „ reserve
1 Flotilla leader
10 T.B. destroyers in full commission
2 „ „ „ reserve
1 „ destroyer depot-ship
8 Submarines
1 Small submarine parent ship.

No effect was given to the report, and it is doubtful if there was ever any intention of doing so.

See *Official History of Australia in the War of 1914-18*, vol. ix; *The Royal Australian Navy*, by A. W. Jose, now (1926) in the press.

J.V.C.-B.

Needle-fish. See Long Toms.

Needle-wood or **Needle-bush,** popular names of *Hakea leucoptera*, a dry-country shrub or small tree from which tobacco pipes are made, the root-stock being carved in the same way as the brier-root (*Erica arborea*) of southern Europe. It is also known as the 'water-tree,' because the roots, when tapped, yield a limited supply of water to aborigines in desert country. Sir T. Mitchell describes (*Three Expeditions*, vol. i, p.197 of the first edition) how some aborigines

Needle-wood.

dug up the roots, cut them into billets, and sucked the abundant watery sap from them. See Hakea.

Nelson, Sir Hugh Muir (1835-1906), born at Kilmarnock in Scotland on 31 December 1835 and educated at the high school and the university of Edinburgh, migrated in 1853 to Queensland with his father William Lambie Nelson, who became a member of the first parliament (1860) but was unseated because he was a minister of religion. For 30 years Hugh devoted himself to squatting, but in November 1883 entered the legislative assembly as member for the Northern Downs. From June 1888 to August 1890 he was secretary for railways in the McIlwraith and Morehead ministries; he led the opposition while Griffith was in office (August 1890-March 1893) and then became treasurer and vice-president of the executive council under McIlwraith. It was a time of financial panic, and Nelson was responsible for measures which helped the colony over the crisis—e.g. the Queensland national bank agreement act and the public depositors relief act. When McIlwraith left for England in October 1893 Nelson took over the premiership in addition to his work at the treasury, and in March 1895 became also chief secretary. During this period there was grave industrial unrest in the colony; a shearers' strike in 1894 (see Strikes) almost became an insurrection, and necessitated the passing of a drastic act for the better preservation of peace. Nelson was opposed to the separation movement which agitated northern and central Queensland during the 1890s, largely because he feared dismemberment would lead to another financial crisis. In 1897 he represented the colony at the Jubilee celebrations and the colonial conference. When his ministry went out of office in April 1898, he became president of the legislative council, and on several occa-

sions acted as lieutenant-governor. He died on 1 January 1906. (K.C.M.G., 1896; P.C., 1897.)

Nemathelminthes, a group of so-called 'worms,' extended by some authorities to include not only Nematoda (round-worms) and Gordiacea (hair-worms) but also the two very aberrant and widely distributed groups Chaetognatha and Acanthocephala. It is probably better to regard these two groups as constituting distinct phyla; for convenience sake, however, both will be dealt with here.

The Chaetognatha comprise certain small transparent (or semi-transparent), free-swimming, marine, bisexual worms, provided with fins on the tail and the sides of the body, and armed anteriorly with numerous long, powerful, sickle-like jaws with which the prey is seized. Their geographical distribution depends largely on ocean temperatures, species which occur at or near the surface in polar regions being found only at considerable depths in warmer latitudes. The group has not been systematically studied in Australia. Detailed work has been carried out only in Shark Bay (Western Australia) and off the New South Wales and Queensland coasts. There are now known to occur in our waters 11 species of *Sagitta,* and one belonging to each of the genera *Pterosagitta, Krohnitta,* and *Spadella* —a total of 14, of which only one (*Spadella moretonensis*) appears to be purely Australian. The last-named lives among seaweed along the east coast of the continent; all the other 13 species are pelagic.

The Acanthocephala or hook-headed worms—all parasitic—are to be found in the adult condition infesting various Australian vertebrates, especially fishes, the black snake, certain birds and (occasionally) bandicoots. Introduced rats often harbour *Moniliformis moniliformis,* and pigs *Macracanthorhynchus hirundinaceus.* The larval stage of Acanthocephala is commonly met with, in an encysted condition, on the peritoneal lining and mesentery of various snakes, and in the subcutaneous tissues of ground-feeding birds. The group has not been thoroughly studied as a part of the Australian fauna; though a few species have been described, they have all been placed in genera that occur elsewhere. Some of the known species are *Echinorhynchus pomatostomi,* a larval form from several kinds of birds; *E. rotundocapitatus* from the black snake; *E. hylae* from the golden frog; *Gigantorhynchus semoni* from bandicoots; and *Centrorhynchus asturinus* from various hawks. Other genera (e.g. *Arhythmorhynchus, Bolbosoma, Echinogaster*) are known to be represented in Australian fauna, but the species have not yet been described or identified.

The Nematoda (usually so called) are divisible into two well-defined groups, true Nematoda and Gordiacea. The latter are the 'horsehair worms,' a name due to their rather stiff, brown, hair-like appearance at the adult, sexually-mature stage; they occur in fresh water, and may at times enter drinking-water. The immature stages are passed through in a coiled condition within the body of certain insects, from which the parasites escape by rupturing the body-wall. This difficult group has not been systematically studied in Australia, only one or two species in their free-living stage having been described.

Nematoda (strictly so called) include both free-living and parasitic forms. The former occur in salt, brackish, and fresh water as well as in damp earth and in all kinds of decomposing vegetation. Of the parasitic forms some are parasitic in plants e.g. the 'eel-worms' of potatoes (*Tylenchus radicicola*), those causing 'ear cockle' of wheat (*T. tritici*), the root-galls of many cultivated and other plants, etc., some of these tiny parasites being extremely resistant to adverse conditions, and able to withstand many years of desiccation. A great many infest animals, from insects and other arthropods to man. Some pass through their larval stages as parasites of an intermediate host, which forms the prey of the final host; or one phase of the life-cycle may be spent in various tissues of the body of an animal, the adult stage infesting only the alimentary tract. Others have a direct development. Some are parasitic during their immature periods only; in other cases it is the young stage which is free-living. Certain Australian species exhibit an alternation of generations—a parasitic, parthenogenetic form (i.e. one which produces eggs and embryos without the intervention of a male) gives rise to free-living sexual individuals, male and female, and the latter, on fertilization, produce young which may develop into free-living forms or into the parasitic stage. The lung-worm (*Rhabdonema* or *Angiostoma*) of frogs is one of these. Another is *Strongyloides stercoralis,* a tiny parasite not uncommon in the human intestine in the coastal districts of Queensland; in its free-living stages it is capable of withstanding desiccation for prolonged periods.

The nematode parasites of the Australian fauna have not been intensively studied, though a number of species from various hosts have been described. In some cases (e.g. the parasites of certain families of birds) the worms belong to species known elsewhere. As might be expected, this is also true of those species found in human beings and in domesticated and introduced animals. The dingo, so far as is known, only harbours species which occur also in the dog.

Certain round-worms that infest man deserve notice on account of their prevalence and their influence on public health. Three are of paramount importance in Queensland—the filarial worm (*Filaria bancrofti*) and the hookworms, *Ankylostoma duodenale* and *Necator americanus,* the latter being more common than the former. The latter two blood-feeding parasites of the intestine are a menace to the development of the race (especially in the moister tropical and sub-tropical regions) through their effects on the health of those affected, particularly when children. So serious is the position in parts of Queensland that a widespread hookworm campaign has been in progress for some years to eradicate the pest. The most efficient treatment has been the administration of either carbon tetrachloride or oil of chenopodium (ascaridol). The eggs, after leaving the victim's body with the faeces, hatch out, and the resulting larvae, after moulting, can re-enter the body either through the mouth or, more commonly, by penetrating the moist skin (especially of the legs and feet), ultimately reaching the lungs, trachea, oesophagus, and finally the intestine, where they attain maturity. Related species occur in the cat, dog, and dingo in eastern Australia.

Filaria bancrofti commonly lodges in the lymphatics, and by obstructing the lymph circulation may cause various organs (e.g. the limbs, breasts, or male genitalia) to become more or less swollen; there may be chyluria and even a marked elephantiasis. The larvae when liberated from the parent reach the blood-stream, whence they may be taken up by certain night-biting mosquitoes;

in these further development occurs, and the larvae eventually enter the proboscis of the insect preparatory to re-entry into the human host when the mosquito bites. The life-cycle of the parasite in the insect requires from 6 to 15 days, according to the temperature. (See TROPICAL MEDICINE.) *Filariae* are not uncommon in birds, especially in Queensland, and are known to infest reptiles and certain marsupials (opossums, wallabies, and kangaroos), the best-known being *Filaria websteri* from the knee-joint of macropods. One species of *Ichthyonema* infests the gonads of certain marine food-fish. Dogs in northern Queensland commonly harbour a filaria (*F. immitis*) in the heart, and its presence often leads to fatal results.

The Ascaridae, though common in some Australian snakes, do not call for special mention, nor do the Heterakidae, some of which have been described from certain Australian birds. The Strongylidae are well represented, especially in wallabies and kangaroos, the parasites belonging to a special sub-family, Cloacininae.

The Oxyuridae occur very commonly in Australian frogs, reptiles, and insects, but have received little attention. The Spiruridae (using the term roughly) are known to infest various hosts, but the group has been very much neglected. A very remarkable worm, *Pneumonema tiliquae*, infests the lungs of 'blue-tongue' lizards (*Tiliqua scincoides* and *T. nigrolutea*); only females of this rather common parasite have been collected; perhaps it is a parthenogenetic form; it is armed with powerful recurved hooks on certain parts of the body.

A few of the nematode parasites of stock need special mention, since considerable work has been done in Australia in elucidating their life-history. These are species of *Habronema*, worms which infest the stomachs of horses, and *Onchocerca*, parasites which occur in the connective tissues of cattle. Of the former there are three species, two of which have been proved able to pass their larval stages in the house-fly and in many related Australian muscoid flies; the third completes its larval period in the stable-fly (*Stomoxys*)—see FLIES. The larvae of one or more of these may gain access to sores or bites on the skin of horses and give rise to certain summer sores (cutaneous habronemiasis). *Onchocerca* is now notorious for involving graziers and others in very heavy losses, since they are compelled to cut out certain parts of any beef-carcase intended for export. This loss amounts to tens of thousands of pounds annually. Three species are known to infest Australian cattle, one, *O. gibsoni*, being the cause of the formation of 'worm-nodules,' especially in the brisket and certain joints. The presence of this long parasite, which lies in a very close, tangled coil, causes an irritation of the surrounding connective tissues, and leads to the formation of a strongly fibrosed area or 'worm-nest' surrounding it. A great deal of research has been carried out in New South Wales, Queensland, and the Northern Territory in the attempt to elucidate the life-history of this species, which is extremely common in the cattle-raising regions of Australia. As yet no indication has been given as to what kind of organism is likely to be a transmitter; experiments with various ticks, flies, mosquitoes, lice, etc., have all given negative results, though a biting fly is likely to be the intermediary. The other two species of *Onchocerca*, though very common in cattle—at least in Queensland—are of little importance economically. One (*O. gutturosa*) especially infests the neck-ligament and certain joints; the other (*O. lienalis*) is found in the gastro-splenic ligament.

In regard to Australian free-living nematodes a considerable amount of work was done years ago by Dr. N. A. Cobb, but since then the group has been neglected. Perhaps distinctly related are certain small marine animals belonging to the Chaetosomatidae, of which four species (two belonging to *Chaetosoma* and two to *Notochaetosoma*) occur in the neighbourhood of Port Jackson.

See for Chaetognatha, Johnston and Taylor in *Proceedings* of the Royal Society of Queensland, 1919; for Acanthocephala, Johnston in *Proceedings* of the Royal Society of Queensland, 1912 and 1918, and *Proceedings* of the Royal Society of New South Wales, 1911; for Nematoda, Sweet in *Proceedings* of the Royal Society of Victoria, 1908-15, Johnston in *Proceedings* of the Royal Society of Queensland, 1911 and 1916. Johnston and Cleland have written on human parasites; Cleland, Johnston, Sweet, and others on onchocerciasis; Irwin-Smith on the Chaetosomatidae, and Cobb on free-living nematodes. These papers will be found in various volumes of the *Proceedings* of the Royal Society of Queensland, the *Proceedings* of the Linnean Society of New South Wales, the *Macleay Memorial Volume* of the same society, the *Agricultural Gazette of New South Wales*, and the *Report* for 1911 of the *Australasian Association for the Advancement of Science*, and the *Transactions* of the Royal Society of South Australia, 1921.

T.H.J.

Nemertinea, an isolated subdivision of worms which Hubrecht and Ray Lankester consider to be in the direct line of ancestry of vertebrate animals; its species are mostly marine. Of the extremely interesting land species one (*Geonemertes australiensis*) is found in Australia and Tasmania. This remarkable little worm has a yellowish cream-coloured stripe on the dorsal surface, the rest of the body being white; there are usually two dark eye-spots at the anterior tip, but the number is variable. When touched, the worm shoots out a long white proboscis, which may exceed the length of its body; this is everted somewhat after the manner of an inward-drawn glove-finger, and is armed with a terminal calcareous spine. *Geonemertes* is found associated with land planarians (q.v.), and in moist weather may be seen in shady localities crawling about on tree-trunks in the open. Though marine Nemertinea may be collected anywhere along the Australian coast, little or no attention seems to have been paid to them. Many are brilliantly coloured, and some are extremely long and delicate. T.S.

'New Australia.' In 1892 'The New Australia Co-operative Settlement Association' was founded by William Lane (q.v.), who had already in 1890 founded Australia's first Labour newspaper—the Queensland *Worker*—and during the shearers' strike of 1891 had been brought into close touch with the station-hands and shearers of western Queensland. Lane's object was to build up a social order based on brotherhood: his appeal to the men of the bush was characteristic:—

> Come together in all unselfishness to trust each other and to be free! To live simply, to work hardly; to win, not the gold that poisons, but the home that saves! . . . Come and work as free men for each other, to labour on the common land for the common good, and not for self alone, or for the selfish greed of another! One man by himself is powerless, but men in a body are strong!

The keynote of the appeal was the desire for a simple home life such as could not in those days be enjoyed by pastoral employees. But Lane's was not the only influence urging Australians at that time towards a socialist community; Bellamy's *Looking Backward* had a great vogue just then with 'arm-chair' socialists, and caused many town recruits to believe that in Lane's community they would find conditions of luxury and leisure approximating to Bellamy's imaginings.

The colonial governments were bitterly opposed to socialism, so that no grants of land could be expected from them; also it was thought that a journey overseas would, like the drinking-test of Gideon's army, keep out all but the really earnest; hence it was decided to migrate to some other country to establish the settlement. As is elsewhere told (see LANE, WILLIAM) recruits enrolled rapidly, and in their own ship the first New Australians left Sydney in July 1893 for Paraguay, where a government glad to get white settlers had generously granted a large area of good land under settlement conditions. But from the first there was no real unity among the colonists; and when, after some expulsions and many secessions, a second party arrived from Australia only to intensify the differences, it was clear that to build up a communal colony with the material in New Australia was utterly impossible. The dissensions which broke up the colony sprang from disagreements as to the essentials of co-operative life; for, though New Australia had enrolled many very suitable colonists, it had also proved a veritable Cave of Adullam to misfits, failures, and malcontents of the left wing of Australian democracy.

In May 1894, 58 people (39 being men, mostly bushmen) under Lane's leadership withdrew from New Australia to begin again the task of building up a communal settlement. The history of this second colony, called 'Cosme' (after the name of a river-ford near which the pioneers camped when waiting to obtain land), must be followed in order to trace the carrying out of the New Australia idea; for after Lane's party left the original colony troubles and dissensions increased there to such an extent that the Paraguayan government, acting on petitions received from various parties of the colonists, wound up the colony as a co-operative concern and gave each settler a block of land for his individual use.

The Cosme colonists bought for £400 on time-payment 16,000 acres of land situated 21 miles from a railway, about 50 miles south-east of Villa Rica, and occupying the fork of two small rivers. The land was half dense scrub and half low grass-land—the scrub soil deep and fertile, the open land good for pasture but useless for tillage. The Paraguayan government afterwards repaid the £400 and granted the land to the colonists on settlement terms. Cosme started with a capital of less than £400, mainly provided by English and Australian friends and the sale of members' personal effects. The women gave their jewellery, even their wedding rings—which last, however, were not sold but returned to the givers. The first months were filled with hard work and hard living. Rough shelters were rapidly erected—tents with grass-thatch flies, huts of saplings with grass roofs and sides. The task of clearing and planting went on with feverish haste, for the season was already late, and during the month before harvest the colonists lived mainly on beans bought on credit from a local storekeeper; but from then on there was a continual improvement in material conditions, though for a considerable time the housing was rough, and the food, though plentiful, was mainly vegetable and not sufficiently varied.

Under the influence of experience and changing circumstances, the Cosme ways of living became modified in detail, but no basic alterations took place throughout 12 years of communal existence. The experiences in New Australia led to the drawing up of a somewhat elaborate constitution, the object of which was to keep the management of the colony in the hands of tried and trusted officials. But as time went on it was found that no one would continue in office without the full confidence of members, so that in a few years the simpler plan of annual elections for all offices was adopted. The colony's affairs were then directed by a chairman, a committee, and an industrial manager; the committee (which met weekly) decided on the general plan of colony business; the industrial manager superintended all industrial matters and reported to the committee. The ordinary general meeting of members was held yearly, but special general meetings could be called at any time. All organized colony labour was co-operative, all males over 15 years of age, and single women over 16, being on the organized staff of workers. There was a 45-hour working week, and disagreeable work was shared round as much as possible. All wealth, except purely personal effects, was owned by the community. Land, houses, crops, machinery, tools, stock, and general goods were all communal property. Members had individual use-hold of house and allotment; such use-hold was permanent, and encouraged the individual to improve his house and to grow fruit or flowers in his garden. All adults had equal shares of colony earnings, irrespective of age, sex, capacity, or occupation. Proportionate shares were given to children according to age. Certain goods easily produced were placed on the free-list, and were served out without limit or charge. Limited supplies of home-grown products were shared equally. Goods bought from outside were supplied to members on an equal-credit system.

Cosme families lived in their own houses. Bachelors had houses of their own, but took their meals in the co-operative dining-room. The work of married women was not organized, and did not come under the direction of the management. Cosme children were reared in their parents' homes under parental control; family life was not interfered with. The income of the family depended solely on its size. Free schooling was provided.

The colony was a 'prohibition' settlement, though only a few of its members were teetotal before joining. There was no official church, members being free to belong to any denomination. Social life was active and varied. A social union managed sports, dances, concerts, plays, and general entertainments. There was a dance every Saturday night in the social hall, and a meeting—not a service—every Sunday night, when readings, recitations, vocal and instrumental music, and occasional lectures were given. The library contained 2000 volumes. A manuscript newspaper, *Cosme Evening Notes*, was published by being read aloud every evening except Sundays for the first four years, after which it became a weekly. The *Cosme Monthly*, a four-page octavo newspaper, was published regularly from the founding of the colony until

1903, when it changed its name to *Cosme* for a few issues and came out as a quarterly. It was printed in the colony and mailed away for propaganda purposes. Cards and draughts were favourite indoor games, and half the men played chess. Cricket, hunting, fishing, and swimming were the chief outdoor sports. The most noticeable effect of communal living was the constantly rising standard of art as evidenced in music, drama, and literature. The early concerts were crude, but singing classes developed musical taste and talent until opera and oratorio were produced and appreciated; the production of plays, too, improved from screaming farce through the comedies of Sheridan and Goldsmith up to Shakespeare. The growth in appreciation of good literature was just as marked, and *Evening Notes* provided a ready outlet and a kindly critical audience for any with a talent for scribbling.

In the early days primitive appliances were used for all kinds of work, but gradually machinery was obtained which made labour more productive; hoes were replaced by ploughs and cultivators, and a steam engine worked saw-bench, cane-mill, and corn-mill. The first Cosme cane-mill was made with wooden rollers and turned by bullocks. The colonists built two bridges to connect the settlement with the railway.

In 1896, the pioneering difficulties having been overcome, William Lane went to Britain for new members, especially for women, so as to give bachelors opportunity to marry. No difficulty was experienced in obtaining recruits, and the population of the colony increased to a total of 131 (November 1897). But the primitive housing and surroundings, hot climate, different and coarser food, insect-pests, rough and unaccustomed work, together with that general strangeness and newness of things so often the cause of homesickness, combined to make most of the new-comers dissatisfied, and soon induced them (especially the women) to forsake the colony. This failure to equalize the sexes very soon caused most of the pioneer bachelors to leave, as they had joined in the expectation of being able to settle down in homes of their own. Withdrawals owing to hardships steadily decreased as the years went by, and the standard of living rose.

William Lane left the colony in 1899, as he felt he could do more effective work by writing for the press; he also wanted to earn money to liquidate a loan which the colony had received and for which he regarded himself as personally liable. His brother John Lane, a pioneer member of the colony, was elected to the chairmanship. In 1901 another effort was made to increase membership. John Lane was sent as organizer to Australia, and no special difficulty was found in getting recruits, but the result was as before, though this time no one left on account of hardships. In May 1904 the population had decreased to 69, of whom only 33 were adults. A white colony in the midst of coloured people must of necessity either grow or lose its racial purity, and the fear of such a fate compelled many sincere co-operators to leave the settlement. In 1905 the colony began to disintegrate, gradually drifting into individualism, and the land and property were finally divided among those who remained. When the war broke out in 1914, practically all the young men of Cosme, and some of the older ones, volunteered for active service, paying their own expenses to England and enlisting there. Those who survived returned to Paraguay.

J.L.

Newcastle, the second city in New South Wales and the third port in Australia, is situated on the shores of Port Hunter—the estuary of the Hunter River—in lat. 32° 57′ S. and long. 151° 49′ E. The port was first entered on 19 September 1797 by John Shortland (q.v.), who had been chasing convict escapees northwards along the coast and was on his way back to Sydney. His discovery of coal (q.v.) near by resulted in a settlement on the banks of the Hunter (then usually called the Coal River); a little coal and a great deal of timber were exported, and in June-July 1801 Louis Barrallier surveyed the district—his map is reproduced in vol. v of the *Historical Records of New South Wales*—but in 1802 King was forced to abandon the settlement because it was too isolated from Sydney to receive proper supervision. In March 1804, however, he was instructed by the colonial office to re-establish it, and on the 15th he appointed Lieutenant Menzies of the marines (then aboard H.M.S. *Calcutta*) commandant of the district of Newcastle. To the village on Port Hunter Menzies gave the name 'King's Town' in honour of the governor; but the name, though it occasionally appeared in official documents till the early 1820s, soon disappeared from popular use, and Macquarie (possibly because he objected to the association of 'King' with anyone except the monarch) invariably used 'Newcastle' for both district and village. When Macquarie visited the settlement in 1812 it was already supplying Sydney with cedar timber, coal, and lime; in 1814 it was sending 154 tons of coal yearly to Calcutta, payment being made in Bengal rum; in 1818 Macquarie congratulated the retiring commandant, Captain James Wallis, on having 'advanced the Settlement at Newcastle, from the Appearance of an humble Hamlet to the Rank and Capabilities of a well laid out, regular and clean Town.' It was Wallis who commenced the breakwater between Nobby's Island and the mainland, which, though not completed until 1857, from the first greatly improved the entrance to the port. Entrance was also facilitated from the earliest days of the settlement by a coal-fire lit every evening on Beacon Head; at midnight on 31 December 1857 this primitive signal was replaced by the lamps of a lighthouse erected on Nobby's. The first church, a temporary structure, was put up in 1812 and services conducted in it by the settlement's assistant surgeon; in 1817 Wallis built Christ Church, 'a very handsome church with an elegant spire,' and in 1821 arrived the first ordained minister, George A. Middleton. Bigge in that year found the settlement orderly and well arranged. The town's seven streets contained 13 houses of government officials and 71 belonging to convicts, besides barracks to accommodate houseless prisoners. Timber-getting, which was the staple industry, was carried on by parties of convicts, sent sometimes as much as 70 miles inland, who returned on rafts formed of the logs they had cut. Coal-mining, which until 1817 had been carried on at a drift on a level with the shore under Beacon Head, was in 1820 done from a shaft 111 feet deep close to the commandant's house; it was unhealthy work, but the 27 men employed could raise 20 tons a day. The worst convicts were employed in lime-burning on the peninsula now called Stockton. Escape from

prison under these conditions would have been far easier than at Sydney, had not the commandants encouraged the neighbouring aborigines to track down fugitives and fetch them back to the settlement disabled and naked. Well-behaved convicts, on the other hand, were allowed to farm land in the vicinity of what is now Maitland; but Bigge succeeded in putting a stop to this humane practice.

In 1821 William Lawson, then commandant at Bathurst, discovered a practicable route from the western settlements down the Goulburn River to the Hunter and Newcastle. Shortly afterwards Governor Brisbane decided to abandon Newcastle as a penal settlement, although convicts were employed there for many years later in the mines.

In 1822 a stone gaol, erected on the site of the present hospital, was converted into a hospital. In 1828 a police-station was built, with George Muir as chief constable; during the same year a post-office was established, the mail-service between Newcastle and Sydney being maintained by the packet *Lord Liverpool*. On 12 June 1831 the *Sophia Jane*, the first steamer to arrive in Australia, visited Newcastle. On 1 August 1839 the Hunter River Steam Navigation Company was formed and imported from England three iron steamers, the *Rose*, the *Thistle*, and the *Shamrock*. In 1831 the Australian Agricultural Company (q.v.) took over the coal-mines; after 1845 competing companies opened up the Newcastle field; and the expansion of trade led to the establishment of a chamber of commerce in 1856. Meanwhile in 1847 Newcastle had become the seat of a bishopric, with Dr. Tyrrell as its first bishop. In 1859 it became a parliamentary constituency, and returned Arthur Hodgson to the assembly. In the same year it was incorporated as a municipality with James Hannell as mayor; it was not proclaimed a city until 1885. A newspaper, *The Telegraph*, had been published in 1855; in 1858 the *Newcastle Chronicle* appeared, in 1867 the *Pilot* (the first daily paper), and in 1880 the *Newcastle Dispatch*. In 1857 a railway was built from Newcastle to Maitland, and was gradually extended northwards to the Queensland border (see RAILWAYS); but not until 1889, when the Hawkesbury bridge (see VIADUCTS AND BRIDGES) was completed, were Newcastle and Sydney linked by rail. The city was first lighted with gas in 1856 by the Newcastle Gas Company; in 1891 electric light was installed. The water-supply, which was in earlier years under the control of the city and suburban municipalities, was in 1893 taken over by the Hunter district water-supply and sewerage board. Newcastle has now two sources of water-supply, one from the Hunter River (hard water), and one from the Chichester River (soft water). In 1914 the State government's dockyard at Walsh Island was officially opened, and in the following year the steel-works of the Broken Hill Proprietary Company (see IRON) were established. The city possesses a technical college and a museum; the new hospital now (1926) in course of erection on the old site will have accommodation for nearly 400 patients. The climate is mild and the average rainfall for the ten years 1914-25 was 36.74 inches. Newcastle has 10 suburbs—Hamilton (which is larger than the city itself, having 16,450 inhabitants against Newcastle's 15,150), Waratah and Wickham (both over 14,000), Merewether, Wallsend, Stockton, New Lambton, Adamstown, Lambton, and Carrington (these range from 7000 down to 3120). The population of city and suburbs combined is 95,070 (all the figures are for 31 December 1924, the latest procurable officially). The following trade statistics are taken from the report of the Newcastle Chamber of Commerce for 1924:

Vessels cleared outward for British, foreign, and interstate ports:—number, 1836; tonnage, 4,101,221.

Total value of imports from British, foreign, and interstate ports:—£1,584,918.

Quantity and value of coal exported to British, foreign, and interstate ports:—4,688,356 tons valued at £5,051,687.

Total value of exports, inclusive of coal, to British, foreign, and interstate ports:—£6,181,177.

Total amount of revenue collected in 1924:—£401,313 19s. 6d.

Value of exports, other than coal, in 1924:—£1,129,490.

N.J.D.

New Guinea. See PAPUA and MANDATED TERRITORY OF NEW GUINEA.

New Norcia. The New Norcia settlement ('Nursia' was the original spelling, after the Italian town where St. Benedict was born) lies on the Moore River about 80 miles NNE. of Perth. It was established early in 1846 by Fathers Salvado (q.v.), Serra (q.v.), and Tootell, with two brothers, as a centre for missions to the aborigines. A monastery was dedicated on 26 April, and, with the help of contributions from Europe, an aboriginal colony grew up round it where the natives were trained to farming, handicrafts, and even telegraphy. On 12 March 1867 Pope Pius IX made the monastery an abbey *nullius dioecesis*, with Dom Salvado as abbot and bishop. On 30 November 1899 he left Australia for Europe, and during a visit to Rome secured his successor, Dom Fulgentius Torres, and arranged the affiliation of the abbey to the Spanish Benedictine province (see BENEDICTINE ORDER). After Salvado's death at Rome on 29 December 1900 Dom Torres was appointed administrator apostolic, and on 2 October 1902 was elected abbot; he died in 1914. The present abbot is D. Anselm Catalan. The mission began with 20 acres; it now has 25,000 acres, 6000 being under cultivation. The abbey, with 50 monks, has within its spiritual jurisdiction 16 square miles of territory, and controls 10 churches, 19 religious and 2 secular priests, 12 monastic students, and 23 nuns. The Marist Brothers and the Sisters of St. Joseph have teaching institutions within its territory, which has a Catholic population of 2600.

See Birt's *Benedictine Pioneers in Australia* (London, 1911); Cardinal Moran's *History of the Catholic Church in Australasia* (Sydney, 1895).

E.M.O'B.

New Protection, THE. The customs and excise duties imposed in 1906 were used for an experiment in economic legislation. One of the arguments repeatedly used against a protectionist policy was that high duties enabled local manufacturers to charge high prices for their goods while paying low wages to their workmen. Accordingly Alfred Deakin, who was convinced that under suitable conditions protection must benefit the employee and consumer as fully as the manufacturer, devised a tariff that should deal equitably with all three. He chose for the experiment the manufacture of stripper-harvesters—harvesting machines originally invented in Australia (see RIDLEY, JOHN and MCKAY, HUGH VICTOR) which manufacturers in the United States were endeavouring to 'dump' on the Australian market.

The customs duties on these machines, and on other agricultural machinery of a similar nature, were increased substantially; but power was given to the government to lower the duties by executive action if it were found that local manufacturers were charging prices above those fixed in a schedule to the tariff act. This protected the primary producer, whose welfare was important to the Commonwealth. To protect employees, an excise of half the amount of the duty was imposed on machinery manufactured in Australia, but might be remitted if the manufacturer proved that he was paying 'fair and reasonable' wages—as defined either by parliament or by some federal or State industrial authority.

The experiment with excise duties was carried farther by a provision with regard to the duties on spirits. If a distiller was proved either to have paid less than 'fair and reasonable' wages or to have employed 'more than a due proportion' of boys in his works, he might be penalized with an extra duty of 1s. per gallon. But this punishment could not be inflicted without special parliamentary sanction.

In New South Wales and South Australia manufacturers obtained exemption under an industrial agreement (see INDUSTRIAL LEGISLATION). Victorian manufacturers, however, on applying for exemption, were faced with a scale of wages which they refused to accept, and on appeal to the high court of Australia it was decided that the whole of this excise legislation was unconstitutional, since the Commonwealth's taxing power could be used only for purposes of taxation, not as a remedial agency in other directions. See TARIFFS.

New South Wales, so named by Captain Cook (at first in the form 'New Wales') from a fancied resemblance of its coast-line to that of Wales, originally comprised all the Australian mainland east of 135° E. long. as well as Tasmania and (doubtfully) New Zealand. The separation of various areas to form other colonies (see COLONIES, CREATION OR SEPARATION OF) has reduced its area to 309,432 square miles; this includes Lord Howe Island, but not the Federal Capital Territory, which is 940 square miles.

Natural Features.—These are described in detail under GEOGRAPHY, ECONOMIC. The colony lies wholly in the temperate zone; its western boundary is the 141st meridian, its eastern the Pacific Ocean, its southern the south bank of the Murray River to its source and then a straight line south-eastward to Cape Howe; its northern boundary is more complicated—the parallel of 29° S. lat. to the Macintyre River, thence that river and the Dumaresq to the dividing range, thence along the northern watershed of the Clarence and Richmond rivers to the sea. The coast-line—700 miles from Point Danger to Cape Howe—has few striking topographical features. The river-mouths are usually obstructed by sandbars (see HARBOURS); but there are three good natural harbours, Port Stephens, Port Jackson, and Jervis Bay, into which no important rivers flow. The surface of the colony comprises three well-marked natural divisions, the coastal region, the two tablelands, and the western plains.

The coastal area is a non-continuous strip of low-lying, well-watered country below the steep edge of the tableland; its average width is 30 miles, but in the Hunter-Goulburn valley it widens to 150. Its rivers are numerous, short, and rapid (fall about 70 feet per mile), rain-fed and therefore liable to floods. Along the more important (the Richmond, Clarence, Macleay, Hunter, and Shoalhaven) lie fertile alluvial lands all suitable for dairying, and, on the Richmond and Clarence, for sugar-growing. The tablelands, which run roughly parallel to the coast from end to end of the State, are separated by the encroachments of the Hunter valley on the east and the Namoi-Peel on the west. They comprise an extensive series of uplands varying from 30 to 100 miles in width and reaching a maximum height in the Kosciusko plateau in the south (highest point 7328 ft.). They present a steep escarpment towards the coast and a gradual slope towards the western plains. Within the southern tableland are situated the Jenolan, Wombeyan, and Yarrangobilly caves (see LIMESTONE CAVES). The plains, which extend from the base of the tablelands to the western boundary of the State, slope gently towards the Darling, and are interrupted by (*a*) the Grey and Barrier ranges near the western boundary and (*b*) a line of elevated country, extending from Orange to Cobar, which serves as a watershed for some of the Lachlan and Darling tributaries. The Darling-Murray basin, a network of inland rivers, covers in New South Wales an area of 230,000 square miles.

Climate.—The mean annual temperature is 59.5°, the mean summer and winter temperatures 68° and 44° respectively. North of Port Jackson the coastal climate is hot and 'muggy' during the summer months; on the western plains it is hot and dry; the tablelands are cold in winter, and snow lies on the hill-slopes of the Kosciusko plateau from March to December. The average annual rainfall along the coast varies from 70 inches in the north to 30 in the south; on the tablelands the average varies from 30 inches in the north to about 25 in the south; on the plains the 15-in. isohyet runs approximately from Barringun on the north through Bourke, Cobar, and Mount Hope to a point west of Moama on the Murray. In the far west the rainfall is 10 inches at Wilcannia and between 8 and 9 at Broken Hill.

History.—The first European settlement in New South Wales was made by an expedition sent from England under the command of Captain Arthur Phillip (see TRANSPORTATION for the object, and FIRST FLEET for the voyage out). Phillip's instructions were to found the settlement on the shores of Botany Bay if the country was suitable; on his arrival there in January 1788, he decided that its many swamps and other defects made it extremely unsuitable. Thereupon with three boats he proceeded to explore an inlet somewhat to the north which Cook had named Port Jackson, and without hesitation chose it. On 7 February, all the members of the expedition being assembled, the royal commission was read by Judge-advocate Collins, and Phillip became

Captain-General and Governor-in-Chief in and over our territory called New South Wales extending from the Northern Cape or extremity of the coast called Cape York in the latitude of ten degrees thirty-seven minutes south to the southern extremity of the said territory of New South Wales or South Cape in the latitude of forty-three degrees thirty-nine minutes south and of all the country inland westward as far as the one hundred and thirty-fifth degree of east longitude reckoning from the meridian of Greenwich including all the islands adjacent in the Pacific Ocean within the latitudes aforesaid of ten degrees thirty-seven minutes south and forty-three degrees and thirty-nine minutes south and of all towns garrisons castles forts and all other fortifications or other military works which may be hereafter erected upon the said territory or any of the said islands.

Following this came the reading of the act of parliament establishing the courts of judicature and the patents under the great seal empowering courts to be convened. The office of lieutenant-governor was conferred on Major Robert Ross of the Marines. Governor Phillip concluded the ceremony by addressing the gathering. He thanked the soldiers, and promised rewards to such convicts as merited it and punishment to evil-doers. Flanagan in his *History of New South Wales* (London, 1862) reports a perfervid address alleged to have been delivered by Phillip on this occasion, but there is no historical evidence to support him.

The erection of buildings in the settlement was slow, and the first settlers were forced to remain under canvas for a considerable period. In the meantime the number of sick was increasing, and scurvy was rife. By July, however, huts and a substantial storehouse had been built, a cottage was being erected for the governor on the east side of the Cove, and an observatory on the west side (now Dawes Point); bricks, too, were being made (see SYDNEY). At first a weekly ration, consisting of 7 lb. biscuit, 1 lb. flour, 7 lb. beef (or 4 lb. pork), 3 pints peas, and 6 oz. butter, was served to the soldiers and men convicts, the women convicts receiving one-third less; but by October a reduction became necessary, so that the men's rations were lessened by 1 lb. flour and the women's by a proportionate amount; not until the *Justinian* arrived with a large stock of supplies on 20 June 1790 was the full ration reinstated and the fear of famine dispelled.

Preparations for defence were commenced in July 1788, when a redoubt on the eastern side of the Cove was begun, and on 4 June of that year the King's birthday was celebrated with a salute (see MILITARY DEFENCE). The governor laid the foundations of the first government house on 26 May 1788, and on 4 June, while celebrating the King's birthday, formally named the district round Sydney 'the county of Cumberland,' noting with pride that it was the largest county in the world. The early attempts to cultivate the land and raise stock were not very successful. They are dealt with under AGRICULTURE, CATTLE and SHEEP.

At first there was considerable trouble with the natives, and murders were of frequent occurrence; these in many, if not most, cases were instigated by outrages on the part of the convicts, whose repeated attempts to escape also added greatly to the governor's responsibilities. Some took to the bush, others stole boats and put to sea in the hope of reaching one of the Dutch islands in the Malay Archipelago. One of these parties—two men and a woman in an open boat—did succeed in reaching Timor, but were imprisoned and sent back to Sydney. The attempts to escape by land usually ended in death in the bush or return to the settlement. Nor was it the prisoners only who troubled the governor exceedingly. Shortly after the first landing he had requested the officers of the prison-guard to encourage diligent prisoners at least with a few kind words, but to threaten with punishment those whom they saw idling or met straggling in the bush. But Major Ross and his officers objected; they were not concerned, they said, in promoting order and good conduct among the convicts. They were sent out on garrison duty; their official instructions were comprised in a letter sent from the admiralty to commanding officers of marines at Portsmouth and Plymouth, and they would govern themselves by that letter, and not by any requests they might receive from Phillip. They had been called upon to sit as unpaid members of the criminal court; as Phillip did not see his way to pay them, they declined to sit, or to interfere in any way with the convicts except those who were immediately employed for their own convenience, or when they were called out at the head of their men. Only Phillip's tact, good temper, and self-control prevented a violent outburst. Ross, who took every opportunity of being aggressive, was, for that matter, on no better terms with the judge-advocate or his own officers, and the constant disturbances and disputes were not ended until he was sent to Norfolk Island as lieutenant-governor.

Phillip's commission gave him power to establish courts of judicature, both civil and criminal. The first criminal court was held on 11 February 1788, and its punishments were prompt and terrible; though the court was supposed to administer justice 'according to the laws of England,' its procedure was carried out in a strictly military fashion. Under the anxieties and worries of his office Phillip's health gave way, and he sailed for England on leave on 11 December 1792. During his term he had displayed great qualities, never failing to meet sensibly and energetically the numerous difficulties which arose. In a vast country he had been set, with the most unpromising materials, to lay the foundations of a colony, establish the machinery of civil government, provide for the administration of justice, develop the resources of unexplored territory, and maintain friendly relations with the tribes by which he was surrounded. The population ruled by him, and composed largely of the worst elements of society, had increased to upwards of 4000, about a quarter being settled in Norfolk Island. To meet their wants a town had been built at Sydney, and smaller settlements established at Norfolk Island, Parramatta, and Toongabbie, around which 1500 acres of land had been brought under cultivation. Explorations (see EXPLORATION BY LAND) had been pushed, largely by the governor in person, to the line of the Hawkesbury and Nepean. Australia has seen no greater achievement than Phillip's. On his return to England he was granted a special pension of £500 a year for his services. For further details of his career see PHILLIP, ARTHUR.

Discontent among officers and men of the marines, and their desire to go home at the expiration of their term of service, made the British government decide to relieve them by raising a corps, to be called the New South Wales Corps, specially for the work of guarding the convicts. The first detachment reached Sydney on 26 and 28 June 1790, but the commander, Major Francis Grose, did not arrive until 14 January 1792. The last detachment of marines embarked for England on board H.M.S. *Gorgon* on 16 December 1791. After Phillip's departure the affairs of the colony were administered by Major Grose as lieutenant-governor from 11 December 1792 to 17 December 1794; Grose then returned to England and Captain William Paterson took his place until 11 September 1795. Grose's administration of civil affairs was characterized by military forms and procedure. He handed over the exercise of magisterial functions to officers of the Corps—one of his first acts being to transfer the magistracy at Parramatta from the justices of the peace to Captain Foveaux. In acting thus he was disobeying instructions; he must have either misunderstood his commission and the letters patent, or have

regarded the employment of justices as within the governor's discretion. When reduced rations were issued owing to a failure of crops in 1793, he abandoned Phillip's practice of equal distribution and made the convicts' ration of flour and rice only half that issued to the rest of the population. He gave large land-grants to both civil and military officers; one of the first officers to receive a grant was John Macarthur, who in 1794 had 250 acres under cultivation at Parramatta. Grose allowed ordinary settlers one or two convicts, supported at the public expense, to assist in the cultivation of land, whereas each officer was given ten and in many cases more. This was not approved of in England, as subsequent instructions showed. During his term of office Paterson did not in any way alter the system Grose had established; he merely 'carried on' till he was relieved.

When it became known that Phillip's health would not permit him to return, Captain John Hunter, R.N., who was then serving on board Lord Howe's flagship *Queen Charlotte*, applied for and obtained the governorship. He assumed office on 11 September 1795, and at once found himself involved in difficulties. The settlement, he complained, was in anything but a flourishing condition; there was scarcely a pound of salt provisions in the store, and no tools of tillage; the military force was insufficient; there was not a barn, granary, or private storehouse in the settlement; finally, he was short of convict labourers and could not carry out necessary public works. He asked for fully 1000 more male convicts, as he could scarcely collect 20 for any public purpose at Sydney, so entirely had they been assigned to the military and civil officers and the principal citizens. In December 1795 he complained further that he had not an article of clothing in the store. Supplies received a year later were soon exhausted, and in September 1798 the people were, 'literally speaking, nearly naked and great numbers without a bed or blanket to lie upon.' No further supplies arrived; the convicts worked in the fields almost as naked as the aborigines, and convicts in the transports *Ganges*, *Britannia*, *Barwell*, and *Hillsborough* arrived with no clothes but those they stood in. The soldiers of the Corps, too, gave the governor trouble. Their officers owned themselves powerless to prevent them from fraternizing with infamous characters, and Hunter suggested to the British authorities (uselessly, at the time) that the Corps should be relieved every three, four, or five years as other garrisons were. A system, introduced by Grose, of purchasing for public use the produce of officers' farms, while it helped to tide over many a period of scarcity, was ultimately the cause of incalculable mischief, for many of the officers soon paid more attention to commerce than to their professional duties. Hunter frequently and bitterly complained of this, and on 1 June 1797 told the British government that

> this spirit of trade, which I must ever consider in the manner it is carried on here to be highly disgracefull to men who hold in their hand a Commission signed by his Majesty, has been carried on so far that it has now reached all the inferior appointments, so that it has absorb'd all their time and attention, and the public duty of their respective offices are entirely neglected, to the no small injury of his Majesty's service.

Although Hunter had so much to complain of, it is clear that he firmly believed in the ultimate prosperity of the settlement. He brought out a number of free settlers, mostly agriculturists, and the settlement expanded during his term of office (see AGRICULTURE and CATTLE). The summer of 1798-9 was remarkable for the first protracted drought on record; for ten months scarcely a shower fell. Then followed a disastrous flood in the Hawkesbury River, which overflowed its banks and swept away the government store and all the provisions it contained. It rose to more than 50 feet above its usual level, and carried all before it—settlers' houses and furniture, live stock and provisions; 'the whole country looked like an immense ocean.'

Explorations by land and sea under Hunter's governorship are narrated under their proper headings, but it may be noted here that in his time the Hunter River and its coal-mines were discovered and worked, a settlement being founded where Newcastle (q.v.) now is. The population of the colony was increased by the frequent arrival of transports with convicts; up to June 1800 37 vessels in all arrived, with about 5000 on board, of whom a little over one-fifth were females.

Hunter's recall was brought about by a quarrel with John Macarthur (q.v.). He was succeeded by Captain Philip Gidley King on 28 September 1800, and on his return to England was granted a pension of £300 per annum. The new governor was not more comfortable than his predecessor in his relations with the Corps. The officers were importing rum, and had even set up stills in defiance of a government order. King was specially ordered to put a stop to this traffic, but was not very successful; he created a storm of indignation among the importers, and greatly embittered the officers, by refusing to allow some thousands of gallons to be landed. The most important events of his term were the initiation of the wool industry (see SHEEP and WOOL), the settlement in Tasmania (q.v.), and the issue of the first Australian newspaper. A revolt of convicts took place among the chain-gangs working on the road to Windsor, near Castle Hill, which although unimportant in itself, revealed to King how dependent he was on the Corps which so constantly gave him trouble, and he begged to be allowed to resign. On 13 August 1806 he was succeeded by Captain William Bligh, a martinet specially chosen with a view to putting down with a strong hand the trade in spirits, in which officers of the Corps still persisted. Accordingly, in February 1807 Bligh issued a general order drawing attention to the evils that had been produced by the trade and prohibiting the exchange of spirits or other liquors in payment for grain, meat, wearing apparel, or any other commodity; but the struggle continued throughout the whole period of his governorship.

When Bligh took office the settlers on the banks of the Hawkesbury and Nepean were suffering from the results of disastrous floods, and his dispositions to relieve them were regarded as infringements of the interests of the private traders. Of these Macarthur was one, and this and other differences eventually led to the illegal deposition of Bligh by the officers of the New South Wales Corps (see BLIGH, WILLIAM). Major Johnston administered the government until Lieutenant-colonel Foveaux returned from England, and Foveaux in his turn was relieved by Colonel Paterson. The government recalled the Corps and sent the 73rd regiment to succeed it, with its lieutenant-colonel, Lachlan Macquarie, as governor. Macquarie's

instructions were to send Johnston to England for trial by court martial and to put Macarthur on his trial before the criminal court of the colony.

Macquarie entered on his long and arduous governorship on 1 January 1810. He could not reinstate Bligh, who was still in Tasmania: it was equally impossible to arrest Macarthur or Johnston, who had gone to England in March; but Macquarie published his instructions to show that the British government supported Bligh, arranged that the Corps should leave for England on 10 April, reinstated the officials whom Macarthur and Johnston had suspended, and cancelled all grants of land or stock that had been issued. Having done this, he proceeded to soothe public feeling by such acts of leniency as were possible. Grants issued in the ordinary course, not as rewards for rebellion, were renewed, and the dismissed officials were protected against malicious and vexatious legal actions. When Bligh came back to Sydney he was helped to obtain evidence against Johnston in all legitimate ways, but his attempts to arouse public feeling were discountenanced. He sailed for England in May, and the colony settled down again (see MACQUARIE, LACHLAN).

New South Wales now entered on a stage of progress. The establishment of schools in which children were not only taught to read and write, but also instructed in useful handicrafts, was followed by a marked improvement in morals. Churches and public buildings were erected, asylums founded, and the better tone given to society generally by the governor was materially aided by his high-minded wife, who laboured to improve the condition of her sex and the children in the colony.

One feature of Macquarie's policy, however, met with much opposition from settlers and military. This was the favour with which he treated 'emancipists' (q.v.). Scarcity was not unknown during this period, and in 1814 the price of bread was fixed by the magistrates at 13½d. for the 2-lb. loaf. In the same year the public stores were relieved of one drain upon their resources by an order from England that the issue of rations and fuel to the families of civil servants (as well as the practice of allotting to each a government servant clothed and victualled at the public expense) should be discontinued. Other privileges of the same sort were cancelled in 1815.

Macquarie's greatest work was his encouragement of exploration and the spread of settlement. In 1811 he visited Hobart and rearranged the system of government, bringing under one head the northern and southern settlements. In 1812 he turned his attention to the extension of settlement in New South Wales, which was still hemmed in by the ranges that had stopped Phillip; it was due to his active support that Blaxland (q.v.) and Evans (q.v.) in 1813 broke through the mountain barrier and opened up the western plains (see EXPLORATION BY LAND and BLUE MOUNTAINS). Macquarie himself crossed the range to fix the site of Bathurst. Journeys of discovery by John Oxley, the surveyor-general (q.v.), and Hamilton Hume (q.v.), an Australian-born settler, also extended the partially-known area of New South Wales from the 2000 square miles or so of 1810 to over 100,000 square miles—from Port Macquarie in the north to Jervis Bay in the south, and inland about 400 miles. The area of actual settlement was also much extended by Macquarie's road-making and bridge-building, and the safety of the settlers was increased by his flood-prevention works in the Hawkesbury valley.

The system of judicature was altered in 1814, a supreme court being established in Sydney with a judge appointed by the Crown. Two magistrates appointed by the governor were to aid the judge. Over all was the court of appeal, presided over by the governor himself, with the judge-advocate as an assessor. No change was made in the criminal court, where the judge-advocate presided (see CONSTITUTIONS). The first judge of the new civil court was Jeffery Hart Bent (q.v.), an overbearing lawyer with whom Macquarie quarrelled almost at once. His refusal to admit to practice an attorney who had been a convict embittered the quarrel and resulted in his never sitting as judge in a case. He was therefore recalled in 1816, to be succeeded by Barron Field (q.v.).

The foundation-stone of a new hospital was laid by the governor on 30 October 1811. To get it built he bargained with three settlers—D'Arcy Wentworth, Garnham Blaxcell, and Alexander Riley—that for building it they should have a monopoly of the sale of spirits for three years (afterwards extended to four). The contractors made great profits, and the colonial office disapproved of the bargain and forbade Macquarie to repeat such experiments (see HOSPITALS). The first bank (the Bank of New South Wales) was established in 1817. The governor's secretary became president of the board of management, and D'Arcy Wentworth and Thomas Wylde held seats on the board (see BANKING). A savings-bank was established in June 1819, Barron Field, James Erskine, Judge-advocate John Wylde, and Sir John Jamison being the first trustees (see SAVINGS BANKS).

By his support of emancipists Macquarie made many enemies, and they were not long idle. Between his dismissal from office and his return to England, Bent made himself a centre of opposition, and complaints went to England. The colonial office began to feel that some investigation was necessary, and in January 1819 J. T. Bigge (q.v.) was appointed a commissioner to enquire into the state of New South Wales. He spent 17 months in the colony, doing his work with great care, and presented three reports to parliament in 1822 and 1823. He did not like Macquarie's pro-emancipist policy and thought him extravagant over public works, but bore witness to the excellence of much of his administration. Macquarie, already tired of the quarrels in which he had become involved, had in 1817 proffered his resignation, which was accepted in 1820; his successor, Sir Thomas Brisbane, arrived in November 1821, and Macquarie left in the following February.

Brisbane, like Macquarie, was a soldier; but his choice did not mean the continuation of the military autocracy which had in Macquarie's time been legitimate. Bigge's reports were known to foreshadow the initiation of a civilian form of government, leading up step by step to representative institutions; and Brisbane (who was attracted to the position by the possibilities it offered of astronomical study under new conditions) left the administration almost entirely in the hands of the permanent officials until Bigge's recommendations were published and carried into effect. In 1823 the machinery of government was remodelled by the New South Wales Judicature act (4 Geo. IV cap. 96), which put an end to autocracy

by giving the governor a legislative council of from five to seven nominees; he could disregard its advice in times of emergency, but must at once submit the dispute to the authorities at home. A supreme court of the British type was established, trial by jury was tentatively introduced, and provision was made for appeals and courts of quarter sessions. The first legislative council, appointed in August 1824, consisted of the lieutenant-governor, the chief justice, the colonial secretary, the principal surgeon, and the surveyor-general; at the same time Brisbane was asked to let the British government have the names of ten merchants or landholders whom he thought worthy of a place on the council, and on his successor's arrival some of these were appointed. Francis Forbes (q.v.) was transferred from a similar position in Newfoundland to be the first chief justice of Australia, and took his seat on 17 May 1824.

The character of the colony was also being revolutionized. Brisbane greatly encouraged the immigration of free settlers, with the result that a number of young moneyed men arrived in the colony, became squatters, and soon made it possible to break up the costly government farms, and to supply the wants of the community with cheaper and better produce. The increased quantity and better quality of wool produced during this period, and the knowledge that free settlers would be welcome, further stimulated immigration; the formation in England of such associations as the Australian Agricultural Company (q.v.) familiarized British capitalists with the notion of investing money in the development of Australia. Settlement of the fertile areas round Bathurst, Goulburn, and Singleton dates from Brisbane's governorship. For the explorations of the period, which were far-reaching and important, see EXPLORATION BY LAND and EXPLORATION BY SEA. Their chief practical results at the moment were the transfer of the penal settlement at Port Macquarie to the newly discovered district of Moreton Bay, and the occupation in 1824 of Melville Island in the far north in order to secure for Britain the possession of all Australian territories within easy reach of the Dutch settlements in Malaysia.

In 1825 the population of the colony was 33,675; there were 237,622 sheep and 134,519 cattle; 45,514 acres of land were under cultivation, and 411,600 lb. of wool were exported. The revenue raised in the colony was £71,682, but a large expenditure devolved upon the crown, which even in 1821 amounted to £425,350.

Brisbane was succeeded by Major-general Ralph Darling (1825-31) a successful but conservative staff officer. His unfortunate controversy with the press has been given so large a place in history that the development of the colony during his administration is frequently overlooked. The legislative council was enlarged to include non-official members, and the first steps were taken to establish a modern judicial system with trial by jury. Expenditure on the convict system, chargeable to the British government, was differentiated from ordinary colonial expenditure, which was met largely by local revenue. Darling was an able administrator and effected the reorganization of departments necessitated by the increasing population and the extension of free institutions. He created a land board to deal with applications for grants, established a department of customs and a regular postal service, and reformed the currency by reducing it to a sterling basis, thus freeing commerce from one of the trammels of the past. Despite the economic set-back in 1827-8 due to drought and over-speculation, the immigration of small capitalists increased from 485 in 1825 to 2016 in 1829; the demand for labour exceeded the convict supply, and private experiments were made in the introduction of labourers under contract. In 1826 settlement was extended in the coastal district, the Illawarra being formally occupied by the despatch of a garrison to Wollongong, and a land-grant at Port Stephens was made to the Australian Agricultural Company; in 1830 the rich hinterland of Port Macquarie was opened to free settlement, the convicts being removed to a new penal establishment at Moreton Bay. More important for the pastoral industry (then the chief source of wealth) was the opening up of the interior by squatters and explorers. Darling was responsible for sending Charles Sturt (q.v.) on the expeditions of 1828-9 which led to the discovery of the Darling River and the exploration of the lower Murray, and during his administration the Darling Downs, in what is now Queensland, were discovered. He checked the ambitions of the emancipists and ruled the convicts harshly; conditions in the road-gangs became worse and many escapees took to bush-ranging, which became a serious nuisance in 1829-30 and was suppressed with difficulty. His continuous controversy with the emancipists and their associates, the native-born, led to his recall.

Bourke, Darling's successor (1831-7), was a liberal and popular man of affairs who for six years succeeded in keeping clear of the exclusive-emancipist quarrel, and was thus enabled to devote his attention to problems of development. Before he took office a fundamental change had been made in the land system, land-grants being abolished and sale by auction substituted, the upset price being fixed at 5s. per acre. So popular was colonial investment that the sale of land increased rapidly during Bourke's administration, the figures being: 1832, 2086 acres; 1833, 29,025; 1834, 91,399; 1835, 271,947; 1836, 389,546; 1837, 370,376. In addition to the land thus alienated large stretches of the western plains were occupied by squatters without permission; Bourke was sensible enough to realize that squatting could not be prevented while the pastoral industry proved so lucrative, and decided to regularize occupation by the issue of pastoral leases. The number of sheep increased from 600,000 in 1829 to 2,750,000 in 1838, and the export of wool from 973,330 lb. in 1830 to 4,606,915 lb. in 1837. There was also an increase in cattle until the end of the thirties, when the home market was supplied and the price fell. This pastoral development was partly at the expense of agriculture, the cultivated area in New South Wales being only 93,000 acres in 1838 as against 108,000 acres in Tasmania, where the yield per acre was twice that of the mainland. The increasing demand for imported foodstuffs is shown by the following figures, 1836 being the peak year:—

Year.	Wheat. bushels.	Flour. lb.	Barley. bushels.	Rice. lb.
1832	44,908	30,072	977	88,052
1836	263,956	4,385,550	27,567	474,358
1837	114,464	1,522,658	7,034	176,030

Pastoral development created a great demand for labour. When the new land system was introduced it was decided to set apart some of the land-fund to assist the migration of

of the said corps for 365 days, as also a state of the subsistence p.d'm.

H.M. is also pleased to direct that the major and capt'ns shall each raise their own comp's, receiving for each approved recruit the sum of three guineas, by which arrangement the charge of raising 300 men (including the serg'ts, corp'ls, and drum'rs) will amount to £945.

Subsequently it was determined that a fourth company should be raised in New South Wales from marine volunteers and officered by a captain and two lieutenants of marines; vacancies could be filled from among the best conducted convicts. This additional company was raised in 1792, and the command given to Captain George Johnston.

Of the personnel of the corps nothing very good can be said. Some of the officers already held commissions—Grose was a half-pay officer of the 96th, Nepean was a marine, Hill came from the 6th regiment, Paterson from the 73rd, Macarthur from the 68th, Foveaux from the 60th, and Fenwicke and Marton from the 22nd. The others came from the militia or from civil life. But it is hardly to be supposed that, at a time when so many opportunities for advancement were offering, officers with soldierly ambitions would have been content to abandon European service for garrison duty in a penal colony, had not private reasons (generally, no doubt, of a financial nature) made such a change desirable. The rank and file consisted principally of men who had made other regiments too hot to hold them, of civilians to whom any change of environment was a welcome one, of prisoners from military penal establishments, and, in some cases, of convicts from English gaols. Writing to Major Grose before the departure of the corps, Sir George Yonge says of one of them:—'It has been represented to me by Major-Gen'l Picton that William Jameson, late a soldier in the 12th Reg't of Ft., who, having been sentenced to death, was pardoned on the condition of serving for life in the corps under y'r C. (command), then actually embarked for N.So.Wales, has been seen at large on shore, and has even appeared at the parade of the 12 Reg't, in which he had committed a crime of so heinous a nature as to have forfeited his life.' It may easily be supposed that Private Jameson was not the only recruit who enlisted for Botany Bay as the lesser of two evils.

Curiously enough, although the past history of many of the privates was well enough known, the officers resented any reference to it. When King in 1803 wished to attach to the corps five conditionally-pardoned convicts whom he had enlisted as a bodyguard, Johnston—then in command of the corps—declared indignantly that it would degrade the corps to have convicts in its ranks. But the use of the corps—and of similar corps in other colonies—for the reception of mutineers or criminals from regiments of the regular army was apparently an understood thing. In 1809 there is record of the despatch of a mutineer from the Indian army to be permanently enlisted in the corps; what is stranger, in 1811-13 deserters from regiments in the Peninsula were still being sentenced to service for life in the corps, although it left New South Wales in May 1810 and had been converted into an ordinary line regiment. It would be interesting to know what happened to these culprits when they reached the colony.

The behaviour of the corps in New South Wales was on the whole better than might have been expected from its origin and composition. Of the men very few complaints were made. King on several occasions emphasized his approval of them: 'the utmost order and regularity,' he wrote on 1 March 1802, 'has uniformly prevailed among the non-commissioned officers and privates.' One incident is enough to prove the corps' efficiency. When the convicts mutinied at Castle Hill on 4 March 1804, the Sydney companies left their barracks near Sydney Cove about 1 a.m., reached Parramatta at 4 a.m., and after a 20 minutes' halt spent the rest of the day in chasing the rebels—probably covering at least 40 miles (Johnston claims 45). Such a performance in hot weather is one that any regiment might be proud of, then or now. Macquarie also, just before he sent the corps back to England, took occasion to praise its discipline and 'orderly good conduct' in the highest terms. Of the officers no good report can be made. They quarrelled with governor after governor; when Phillip went home on leave and they were in power, they used it to destroy all his carefully laid plans for the growth of the town, which they disfigured by taking up allotments where they chose and forcing the roads into crooked courses. Their trading, especially their traffic in 'rum' (i.e. spirits of any kind, more particularly those distilled from wheat), was an unceasing scandal (see CAMPBELL, ROBERT and RUM, TRAFFIC IN); and it was they who led the corps into the mutiny against Governor Bligh with which its name will always be unfavourably associated. The immediate consequence was that Macquarie, on his appointment as governor, received orders to ship the corps (including 'every officer') back to England. It had in 1809 become the 102nd regiment, and left Port Jackson on 12 May 1810, returned to England via Cape Horn (the only British regiment that has circumnavigated the globe), and in January 1812, while stationed at Guernsey, was placed under command of Charles Napier. 'The state of discipline in that corps' ran his letter of appointment, 'requires that you should join it without loss of time.' In June it was ordered to Bermuda, and under its new commander improved in every respect (except in regard to its drinking habits), having the fewest men in hospital of any regiment there. Napier made it an excellent force, but had no opportunity of testing it in battle; it left Bermuda for garrison duty at minor stations, and in 1818 was disbanded.

Not yet, however, was it quite dead. From among the privates with long service Macquarie selected enough to bring up his own regiment to within 19 of its full establishment, and enlisted another 100 as a 'veteran' or 'invalid' company for garrison duty in New South Wales. In 1817 its members were past their prime, and Macquarie reported that 25 real soldiers would be more efficient than the whole company; it was, however, still nominally in existence in 1822 and was not finally disbanded until 1823. Meanwhile the war office did not know what to do with the disbanded units of the 102nd, many of whom seem to have cherished happy recollections of the colony. Accordingly in 1825 volunteers were called for among them to reconstitute the New South Wales Corps, and a body of men under that title reached Sydney on 8 July 1826 and was put under command of Colonel Dumaresq, Darling's brother-in-law; it, too, is sometimes called 'the Veteran Corps,' or 'the Royal New South Wales Veteran Companies.' In 1829 it numbered 3 captains, 3 lieutenants, 10 sergeants, 11 corporals, and 130 privates, and was distributed among seven stations in New South Wales, one at Norfolk Island, and two in

Tasmania. The *Monitor* of 20 February 1830 announced its dissolution; but, according to the *Australian Almanac* of 1832, at the beginning of that year it still contained 54 officers and men. Its final disbandment seems to date from 1 April 1833. J.H.M.A.

New Zealand up to 1841. Closely as New Zealand has always been associated with Australia, its history has run a very different course. This is due partly to geographic and climatic differences, and partly to the very different type of inhabitants whom the white men found there. The Maoris, whom the first settlers found occupying in some strength the greater part of North Island and the northern part of South Island, are far from being mere wandering savages like the Australian aborigines. They are a branch of the great Polynesian race, which had at no very early date (probably about the 13th century) displaced an earlier race akin to the Moriori of Chatham Island. Divided into fairly strong tribes, the Maoris cultivated the soil, fished, and built large sea-going canoes. Both mentally and physically they rank high amongst barbarian tribes. They were continually engaged in war among themselves, and, though they were still in the stone age, had brought the science of fortification to a high pitch, as the remains of their pas (fortified villages) show. Fighting was literally meat and drink to them, for they were inveterate cannibals.

Much of the early history of New Zealand is made up of quarrels and wars between Maoris and invading white men. A special source of trouble was the fact that the English settlers were quite ignorant of the Maori law of *tapu* (things sacred or forbidden). By acts that seemed innocent to them they often quite unwittingly outraged the deepest and most sacred feelings of the Maoris, and aroused a desire for revenge. Some visitors, like Cook and Marsden, tried to understand and to respect Maori feeling; only too many despised what seemed to them irrational prejudices—and did so often to their cost. Further, except in the east of South Island New Zealand had not the large areas of open pasture lands, easily and rapidly occupied by sheep and cattle, that are found in Australia. Where it was not cultivated by the Maoris, the country was for the most part covered with forest, scrub, or fern.

It is possible that New Zealand was sighted by Portuguese or Spanish navigators at an early date; but there is nothing to prove that any part of it had ever been seen by a European navigator before Tasman's voyage of 1642. On 18 December 1642 Tasman anchored in Golden Bay. Next day the Maoris came out in canoes, attacked a Dutch boat, and killed three men. Tasman promptly made sail from the place, which he called Murderers' Bay; he suspected the existence of Cook Strait, but was prevented (he said) by contrary winds from making sure; so he sailed up the west coast of North Island and past the Three Kings, not landing anywhere. He called the new land 'Statenlandt;' the name was altered to New Zealand a little later, when it was proved that it could not be connected with Statenland near Cape Horn.

The next European visitor was James Cook (q.v.), who first sighted the coast on 7 October 1769, spent nearly six months in a circumnavigation, and sailed for the mysterious New Holland on 1 April 1770, after taking formal possession of South Island. A little after Cook's first landfall (on 16 December 1769) the French navigator De Surville anchored in Manganui harbour. The Maoris received him kindly, but he suspected them of stealing a boat, burned their village, and kidnapped a chief, who died on the voyage. In April 1772 another French navigator, Marion du Fresne, who had sailed from Mauritius on a voyage of discovery with the ships *Mascarin* and *Marquis de Castries*, visited New Zealand. For a time all went well, but on 12 June Marion and 16 of his men, who had gone ashore to cut spars, were killed by the Maoris, as were several men who went in search of them. The reason for the massacre is not known, but it has been conjectured that the French cut *tapu* trees. Crozet, Marion's second in command, took stern vengeance, and for a long time afterwards the Maoris remembered with bitter feelings the 'tribe of Marion.'

In March 1773 Cook, on his second voyage, visited Dusky Sound. Six months later nine men from his consort, the *Adventure*, were killed and eaten by Maoris at Grass Cove in Queen Charlotte Sound, and this time the murderers escaped scot-free. In 1777 Cook visited New Zealand for the last time, anchoring in Queen Charlotte Sound on 12 February, and leaving on the 27th. In 1788 Bligh, on his way to Tahiti in the *Bounty*, passed south of New Zealand and discovered the Bounty Islands. Vancouver, who, like Bligh, had been with Cook in 1777, visited Dusky Sound in 1791, on his way to the north-western coast of America. His companion Broughton, who commanded the *Chatham*, discovered Chatham Island away to the east; it was then inhabited by the Morioris, who are supposed to be close kin of the race that inhabited New Zealand before the coming of the Maoris.

On 22 November 1791, the month in which Vancouver visited Dusky Sound, Captain Ebor Bunker left Sydney in the whaler *William and Ann* with the intention of calling at Dusky Sound, but whether he did so is not recorded. In the same month two vessels tried whaling out of Sydney, but met with little success owing to the rough weather. Within the next few years, however, several whaling-ships were working off the coast of North Island.

In November 1792 William Raven—master of the *Britannia*, owned by the Enderbys—came to Dusky Sound to obtain seal-skins for the China market. He built huts for the sealers, and 11 men, with provisions and stores for 12 months, were landed at Luncheon Cove when the *Britannia* left for the Cape of Good Hope on 1 December. On 8 September 1793 Raven returned, accompanied by the *Francis* (the first vessel completed in Sydney), and took off the sealing-gang, which was in excellent health but had procured only 4500 skins. They had in building a vessel of New Zealand pine, which was left at Luncheon Cove; two years later William Bampton found his ship the *Endeavour* (not Cook's ship) leaky, ran her ashore in Dusky Sound, completed the other vessel, named her the *Providence*, and sailed her to Sydney with as many of his crew as she could hold. The *Providence* was the first vessel built in Australasia from Australasian timber, as the *Francis* had been sent out in frame and only completed with Australian timber. On his return Raven gave an excellent report of the timber, especially the pine obtainable at Dusky Sound. In 1794 the snow *Fancy* (Captain Dell) was in the Firth of Thames in the North Island for some time, timber-getting, including 200 trees, from 60 to 140 feet in length, for the

use of the East India Company. This was the beginning of the New Zealand timber-trade. It was not without bloodshed, for the Maoris stole some axes and were fired on, two men and one woman being killed. Raven had a three years' trade licence from the East India Company. In 1795, when whaling became profitable, legislation was passed fixing limits for the southern whale-fishery, and still keeping New Zealand and New Zealand sealing under the dominion of the East India Company. In 1797 the board of trade considered a petition of 'merchant adventurers of the southern whale-fishery' for an extension of limits, and in 1798 the extended limits were granted by legislation. On 30 December 1801 three Enderby brothers and two Champions secured a further extension, which opened the whole southern ocean for fishing, provided the vessels delivered their journals to the directors of the East India Company on returning to England.

In the meantime King at Norfolk Island, anxious to treat the 'New Zealand flax' (*Phormium tenax*) properly, asked Vancouver to induce two Maoris to come over to instruct his people. Vancouver gave instructions to Lieutenant Hanson of the store-ship *Daedalus*, and he went off to the Bay of Islands, beguiled two young chiefs on board, and took them to Sydney, whence Grose sent them on to Norfolk Island. There they declared that flax-dressing was the work of women, not of chiefs; but King treated them with great consideration, learned from them what he could, and then himself took them back to New Zealand in the *Britannia* at the end of 1793. In February 1793 the Spanish explorer Malaspina, with the corvettes *Descuvierta* and *Atrevida*, anchored in Doubtful Sound, but made no important discoveries. In 1800 King, then governor of New South Wales, ordered the commandant at Norfolk Island to send to the Bay of Islands a selection of useful live-stock as a present to Te Pehi, a powerful chief who had been friendly to the English since King had sent back the two young chiefs; and in 1806 Te Pehi and four of his sons visited Sydney and were entertained by King and Samuel Marsden. (See BRUCE, GEORGE.) In 1801 Bass (q.v.) visited Dusky Sound to procure timber for making pork-barrels, and incidentally salved from the wreck of the *Endeavour* a good deal of old iron (his visit to the Sound shows that it was already well thought of for its timber); and when on 5 February 1803 he left Sydney on his last 'pork voyage' his intention was first of all to visit the Sound again and get what was left from the wreck.

Meanwhile the Australian sealing-grounds, in Bass Strait, seemed near exhaustion. In April 1803 Joseph Oliphant, master of yet a third *Endeavour* (a 31-ton schooner this time), after leaving part of his crew on Cape Barren Island went off to Dusky Sound and with great difficulty procured about 2000 skins. In 1804 the whaler *Scorpion* followed his example. Whaling had been carried on off the New Zealand coast since 1794, and occasionally crews settled ashore in the off season (especially along the Bay of Islands), took Maori wives, lived in raupo huts, and grew vegetables and hunted pig; Maoris, too, served aboard these whalers as seamen or harpooners, but were often badly treated. In 1804 an American vessel, the *Union*, while sealing for the China market, discovered the Antipodes group of islands and put a gang ashore there, which after a year's work had collected 60,000 excellent skins. Soon the Snares and Bounty groups were visited for the same purpose, and in 1806 the Auckland group was discovered and added to the sealers' list. The trade thus established (which is separately discussed under WHALING AND SEALING) lasted in full vigour until 1820, but then began to decline, and by 1829 was practically extinct. Whaling for a short time took its place.

One of the early sealing ventures gravely affected New Zealand history. In 1807 the *Santa Anna* (a Spanish prize owned by Lord, Kable, and Underwood) left the Bay of Islands for the Bounty group with a Maori chief, Ruatara, who desired to visit England and see King George. For six months he was left on the Bounties with a sealing-gang, and then taken to England. In London (which he reached in 1809) Ruatara was as far from seeing the king as ever, and fell ill; the master of the *Santa Anna* obtained for him a return passage to Australia by the convict ship *Ann*; and aboard her, ill and miserable, he was discovered by Samuel Marsden, who had come to England to enlist missionaries for New Zealand. Marsden took Ruatara under his charge, nursed him back to health and, when they reached Sydney in February 1810, put him up until a ship could be found to take him back to New Zealand. It was Ruatara who introduced wheat into New Zealand. Marsden, intent on his mission, had brought with him William Hall (a carpenter and shipwright), Thomas Kendall, a schoolmaster (see KENDALL, HENRY), and John King (a flax-spinner), who meant to carry on their religious and secular duties side by side; but almost simultaneously with their arrival in Sydney there came from New Zealand news of a massacre which induced Macquarie to forbid for the time any attempts to settle in the islands. The ship *Boyd*, trading along the north coast for timber, had a certain Tara, a chief of the Whangaroa tribe, among its crew. For some misdoing the master flogged him—a grave breach of Maori *tapu*—and when Tara reached Whangaroa and told of his disgrace the tribe massacred the whole crew except a woman, a boy, and two small children; these Te Pehi, as dominant chief of the district, managed to save (see BOYD, BENJAMIN). The result was unfortunate for Te Pehi; some English whalers burnt his village under the impression that he had joined in the massacre, and Tara's friends killed him for siding with the white transgressors of their law. Not until the end of 1813 did Marsden obtain from Macquarie permission to send his missionaries to New Zealand, and even then he was forbidden to go himself. In March 1814, therefore, he sent off Hall and Kendall in the brig *Active* to get into communication with Ruatara. In August the brig returned with the missionaries, Ruatara, and two other chiefs, and on their favourable report Marsden was given four months' leave and allowed to visit New Zealand. On 28 November he sailed with Hall, Kendall, King, and the Maoris, reached the Bay of Islands on 22 December, preached his first sermon there on Christmas Day, bought 200 acres of land for 12 axes, and left the newly formed settlement for Sydney on 25 February 1815. By 2 August he was back again, bringing with him 22 settlers; this involved the acquisition of more land, but he obtained without difficulty from Hongi (Ruatara's uncle) 13,000 acres at Kerikeri, a good site for a seaport town. The price was 48 axes.

At this time it was estimated that there were from 100,000 to 110,000 Maoris in the North Island. The leading chiefs were Hongi in the

north and Rauparaha at Kawhia on the west coast. Hongi, often described as the ablest man of Maori race, was an ambitious man and a fierce warrior, but he persistently protected the mission settlements. He was determined, however, to master the North Island, and saw that with fire-arms he could do so. Marsden flatly refused to trade in fire-arms. Hongi refused to trade in anything else. When he found Marsden still immovable, he went off to England with Kendall (now a magistrate), was entertained by George IV, and helped in the preparation of a Maori grammar, the vocabulary for which had been obtained in 1818 from two other chiefs, Tui and Titore. The king gave Hongi many presents, including a suit of armour; Professor Lee, the grammar-compiler, gave him money for his aid; the Quakers gave him ploughs and harrows; Marsden's friends gave him watches, tools, clothes, and furniture. When he reached Sydney on his return, he exchanged all these presents (except the armour) for 300 muskets and ammunition; with this precious cargo he hurried back to New Zealand, collected war canoes, surprised a hostile tribe, and slew 1000 men. Small tribes were mown down, and successful expeditions led against others. For five years he continued at intervals these destructive wars; but through all his bloodshed, and despite his disregard of Marsden's admonitions, he always reverenced Marsden himself, protected the missionaries, sent his children to their schools, and when he died told his tribe to 'be kind to the missionaries, for they do much good and no harm.'

Meanwhile the settlement had not been prospering. Marsden had provided a carpenter and a flax-spinner, but, although a good farmer himself, had forgotten to bring farmers or farm-labourers. Ten years after the first cattle had been landed at the Bay of Islands there were only about 30 head there. Most food-supplies were obtained from Sydney or England, and it was 15 years before it occurred to any responsible person that settlers ought to learn to grow their own food. In March 1830 Marsden during one of his periodical visits bought 250 acres of farmland nine miles from the coast; on 3 November 1832 a plough was put in, and soon afterwards a mill was erected and flour ground not only for the settlers but for Maori cultivators. In 1835 Charles Darwin noticed that the farm was flourishing.

Other missionaries visited the North Island, but did not prosper, finding no great chief to protect them. A Methodist colony that had been planted at Whangaroa in 1822 was forced four years later to take refuge at Kerikeri, and returned to Sydney in February 1827. In that year attempts were also made to establish a trading settlement at Hokianga. A New Zealand Company formed in London in 1825, with Lord Durham and Colonel Torrens as promoters, sent out two vessels with a few settlers, who bought land from the Maoris at Hokianga and Manukau but abandoned the enterprise almost immediately; they said the trade was not profitable enough, but the generally believed story is that they happened on a *haka*, heard talk of tribal wars, and thought themselves safer in Sydney. Undeterred by this report, Thomas Raine of Sydney in the same year settled at Hokianga, began to build small craft, and exported spars and flax; two years later he was prospering, and his only complaint was that the Sydney authorities did not feel themselves empowered to put his vessels on the Sydney register.

The exact status of New Zealand at this time was doubtful. Although Phillip had been commissioned to include in his sphere of rule 'all the islands adjacent in the Pacific Ocean,' and King and Macquarie interpreted this phrase to cover even Tahiti, later governors were stricter. Brisbane submitted to Bathurst that a definite decision was required as to the meaning of the phrase, which had been repeated in every governor's commission since Phillip's time; he also asked that 'distinct powers of negotiation, both with New Zealand and the Islanders of the South Seas' should be conferred on him. Bathurst carefully avoided answering the question, but British acts of parliament passed in 1817, 1823, and 1826 definitely include New Zealand among 'islands or countries not within His Majesty's dominions.' It is strange that Brisbane's attention had not been drawn to the act of 1817, which incidentally gave the New South Wales courts jurisdiction over crimes committed by British subjects settled in New Zealand. Though Darling's commission contained the same vague clause about 'adjacent islands,' in Bourke's the wording was altered to 'all the islands adjacent. . . . and also including Norfolk Island'—a phrasing which *a fortiori* excluded New Zealand from the 'adjacent' islands.

About 1829 the disturbed state of New Zealand began to trouble the authorities in Sydney. Rauparaha, who had long since determined to rule central New Zealand as Hongi ruled the northern part, was by 1828 established on Kapiti Island in the mouth of Cook Strait, and from that centre dominated the Wanganui bight and the strait, and ravaged the South Island as he chose. Towards the end of 1830, his uncle having been killed in a raid on Kaiapoi, he persuaded an English shipmaster to aid him in a treacherous attack on the Kaiapoi tribe, after which its chief and his wife were tortured to death; in a later attack the tribe was practically exterminated, and the affair concluded with a cannibal feast. This and similar if less ghastly reports from other districts stirred Darling to urge intervention. He had already, on 12 August 1830, reported that the whaler crews were usually profligate and uncontrolled, that the traders from Sydney connived at the escape of convicts, and that order could only be maintained either by the establishment at the Bay of Islands of an official with a few troops, or by stationing on the coast a small armed vessel commanded by a naval officer. In April 1831 he reported the Kaiapoi outrage: pointed out that, though Rauparaha might have acted 'according to his notions,' the English shipmaster aided in the massacre purely to obtain a cargo of flax; and announced his determination to send an official resident to New Zealand at once and to prohibit the traffic in dried human heads. Collett Barker (q.v.) of the 39th regiment (who had been commandant at Raffles Bay) was Darling's first choice for resident; when he was killed by aborigines at Encounter Bay, Darling suggested Sturt, who happened to be at Norfolk Island. This appointment, however, was postponed on account of Darling's recall, and Goderich, while praising his energy and adopting his suggestions in principle, preferred to appoint a civilian. Almost at the same moment (on 22 December 1831) Bourke and his council decided that any resident would be powerless unless he were backed by troops. In March 1832 Goderich decided to appoint James Busby (q.v.), but to leave him unsupported by troops; he asked the admiralty to detach a small vessel for New Zealand service, but all that could be

obtained was an instruction to the admiral in charge of the East Indies station that occasional visits should be paid by warships.

Busby's position was thus extraordinarily difficult from the beginning. His influence, as he himself wrote, was to be 'altogether of a moral character.' Goderich provided him with a letter from William IV to the chiefs of New Zealand—a candid letter, in which the hope was expressed that 'no circumstances may occur in future to interrupt the Internal tranquillity of New Zealand, which is so necessary to the maintenance of a close commercial Intercourse between the Inhabitants and those of Great Britain.' Bourke gave him long and involved instructions, most of which were impossible of performance without an armed force to back him. He was, said a contemporary, 'a warship without guns.' On 21 April 1833 he left Sydney for New Zealand, reached the Bay of Islands on 16 May, and at once began to confer with the chiefs. The first result was a proposal to establish a national flag for New Zealand; Bourke sent off three patterns, the chiefs (or as many of them as could be got together) chose one, and it was hoisted on 20 March 1834 and saluted with solemnity by the guns of H.M.S. *Alligator*. But this did not in any way aid the cause of peace, and in September Bourke told the colonial office flatly that, unless a warship was permanently stationed in New Zealand waters, he would recommend the recall of the resident and the placing of settlers in the islands outside the pale of British protection.

In December Bourke returned to the charge. Busby, he said, had no naval backing, no legal authority to arrest British offenders; such authority as he had was almost totally disregarded by Europeans, and did not impress the Maoris. It was, however, mainly the white population that gave Busby trouble. When in May 1834 his house was attacked, although he did not discover the culprit until October, yet as soon as the discovery was made fourteen chiefs assembled, made a fifteenth confess his guilt, and declared his land forfeit to the British king. In the face of this action the repeated assertions of the colonial office that Busby had failed to obtain the chiefs' confidence are shown up as an attempt to evade its own neglect to provide him with any support.

In 1835 trouble of a new kind arose. An adventurer of French parentage, but with British military service to his credit, who styled himself 'Charles, Baron de Thierry,' had in 1822-3 bought from chiefs through Thomas Kendall a few hundred acres at Hokianga, and had asked Bathurst for British protection in case he founded a colony there. Bathurst having replied that New Zealand was not a possession of the British crown, the Baron applied for French protection, was again refused, and dropped the scheme. In 1835, however, he turned up again. He had conceived a plan of extraordinary magnificence, considering its date; he proposed to dig a canal across the Panama isthmus, annex New Zealand, make himself king of it, and establish a fortnightly mail service across the Pacific from Panama via Tahiti to the Bay of Islands, Sydney, and Hobart. New Zealand, it may be noted, was to pay for the canal. The mail service was to be started in August 1835, without waiting for the construction of the canal. In May he petitioned the British crown for aid and protection in this enterprise; in September he had reached Tahiti on his way to his new kingdom, and thence notified Busby of his intentions. Busby acted promptly; he called a meeting of chiefs (mostly from the districts immediately surrounding the Bay of Islands), and persuaded them to constitute themselves a federation, 'The United Tribes of New Zealand,' self-governing but under British protection. Unfortunately he imported into this declaration of independence a clause interfering with the right of individual districts to prohibit the importation of ardent liquors, and this greatly disturbed both Bourke and the authorities in London, so that the scheme for British protection fell through. In 1837 the Baron reached Hokianga with 93 followers. Most of the chiefs openly denounced him as a pretender, but one recognized his claim to the Hokianga land, and finally gave him 1000 acres, on which he settled down. In the same year a Roman Catholic missionary, Father Pompallier, was despatched from France to labour among the Maoris, and in 1838 he settled at Kororareka with two priests. A little later the Nanto-Bordelaise Company was formed to found a colony at Akaroa in the South Island, on land provisionally purchased by one Langlois, master of a French whaler, on 2 August 1838.

All this movement on the part of France drew the attention of the British government to the necessity for securing in some way a definite hold on New Zealand. Yet there might have been more delay had not Edward Gibbon Wakefield (q.v.), fresh from his activities on behalf of South Australia, in 1837 turned his attention to the islands, obtained the co-operation of Lord Durham, and formed the New Zealand Association. After long argument and an attempt in 1838 to pass a bill through parliament, the scheme fell through. But in 1839 Wakefield and his friends took matters into their own hands, formed a New Zealand Company (with a capital of £100,000) for colonizing the territory on Wakefield lines, sold in London 100,000 acres of land that was not yet bought in New Zealand, and chartered a ship, the *Tory*, which left England in May 1839 with a first batch of settlers under the leadership of Wakefield's brother William. This direct action at last roused the colonial office to establish British authority in New Zealand. On 15 June the boundaries of New South Wales were officially extended to include such portions of New Zealand as the crown might acquire, and Captain William Hobson (q.v.) was despatched to New Zealand as lieutenant-governor.

William Wakefield reached Queen Charlotte Sound in August, and went to work at once. His orders were to be frank with the natives, to make no bargains without being sure that all the owners were approving parties and that each received his due share of the purchase-money, and to see that all transactions were thoroughly understood by the chiefs and the tribes at large. He disregarded these instructions altogether. Fearing missionary interference, he hurriedly bought land from chiefs (or even from inferior men) without reference to the tribes; the land mentioned in his documents stretched beyond the possessions of the tribes with whose members he dealt; he did not even assure himself that any man signing his documents knew what the documents meant. A whaler named 'Dicky' Barratt, who knew a little Maori, explained a few points clumsily to the chiefs: that was all. Moreover, he made payments in fire-arms and ammunition. In the price of 20 million acres which he claimed

to have bought in the Wellington and Taranaki districts were included 239 fire-arms, 81 kegs of gunpowder, and 2 casks of ball cartridges, besides nightcaps, pipes, Jews' harps, and sealing-wax.

Hobson, meanwhile, had reached Sydney, consulted Gipps, and drawn up a proclamation announcing that no purchase of land in New Zealand would be recognized without enquiry and ratification by British land commissioners. Then he went on to the Bay of Islands, proclaimed the foundation of the colony, and called the chiefs together at Waitangi, where Busby lived. There, after a full explanation and two days' discussion, was concluded on 6 February 1840 the famous treaty of Waitangi, the first clause of which yielded to the Queen of England 'all the rights and powers of sovereignty' which the chiefs had in their districts; the second guaranteed to the tribes 'full and undisturbed possession of their lands,' and provided that, if they were sold, the first offer must be made to the British government; the third gave the Maoris all the rights and privileges of British subjects. Armed with this well-discussed and thoroughly understood treaty, Hobson next demanded particulars of all land-claims urged by Europeans. He found that they amounted to more than half the area of the islands. Out of a total of 72,000 square miles claimed by self-styled purchasers, 68,000 had been purchased in the last two years. The land commissioners soon discovered how preposterous many of the claims were. The New Zealand Company was only one of many powerful claimants; W. C. Wentworth (q.v.) and a Sydney syndicate had obtained large grants in the South Island from five petty chiefs who visited New South Wales. But Gipps stood by Hobson, and the Sydney speculators lost their claim.

Hearing that a French expedition had been despatched by the Nanto-Bordelaise Company to occupy Akaroa, Hobson on 21 May 1840 proclaimed British sovereignty over all the islands of New Zealand, had the proclamation repeated during June at ports in Middle (South) and Stewart islands, and on 22 July sent off H.M.S. *Britomart* with two magistrates aboard her to hold formal courts at Akaroa and other ports, so that the annexation could not be objected to on the ground that British authority was not being actually exercised. This was done at Akaroa on 11 August. Meanwhile the French expedition, accompanied by the French warship *L'Aube*, had reached the Bay of Islands on 11 July, and had been informed of the proclamations of May and June. It reached Akaroa on 15-16 August, and the French settlers were allowed to land and occupy (after paying the full price agreed on) the land that Langlois had purchased; in the end the Nanto-Bordelaise Company was allotted 30,000 acres, but could not keep its settlement alive, and sold out to the New Zealand Company for £4500. For a full discussion of this episode see Andersen's 'Mission of the *Britomart*' in the *Transactions* of the New Zealand Institute, vol. lii.

It was not the French but the British would-be settlers who gave Hobson most trouble. They resented his interference with their land-claims, despised or disliked his friends the missionaries, and objected strongly to the superior authority of Gipps, who invariably and rightly backed Hobson. The company's settlers clamoured for the land that had been sold to them in England. The company said that Hobson was withholding it, and appealed to Gipps, who agreed to allow it about one part in a hundred of its claimed area. Then action was taken in London, where the ministry in office was weak and the company's friends (Lord Durham especially) were strong. On 3 May 1841 New Zealand was severed from New South Wales, thus getting rid of Gipps. Hobson was made first governor of the new colony, but with definite instructions from London to allow the company an area in proportion to its expenditure, calculated at the rate of five shillings per acre. This increased the area at its disposal from 110,000 acres (Gipps's award) to 1,000,000. The company, emboldened by so easy a victory, went on to demand that it should have the power to select this amount anywhere it liked, and to call on Hobson to arrange the purchase of its selected blocks; but just then a new ministry came into power in England, Durham and his friends found themselves without influence, and Hobson, abiding strictly by the treaty of Waitangi, was able to administer the colony's affairs without succumbing to overmuch pressure from avaricious and unscrupulous white claimants. The rest of his term of office, however, belongs to the history of New Zealand as a colony, and so lies outside the sphere of this volume.

Nichols, George Robert (1809-1857), son of Isaac Nichols (q.v.), was born at Sydney on 27 September 1809 and educated in England. On his return to Australia he was articled to the crown solicitor, and on 1 July 1833 admitted to practice in New South Wales—being so far as is known, the first native-born Australian admitted. He practised in both branches of the profession, since they were not separated until 1834. During the 1830s he was closely associated with Wentworth and Bland in the Patriotic Association (see Wentworth, W. C.), in 1840 was part-proprietor and editor of the *Australian*, and in 1848 was elected to the legislative council for the Northumberland boroughs, which constituency he represented until its dissolution in 1856, and then in the legislative assembly until his death. In 1856 he became auditor-general and secretary for lands in the first ministry. He died on 12 September 1857.

Nichols, Isaac (1770?-1819), was transported to New South Wales in 1791, but was soon freed, and became a successful farmer. In 1796 Hunter appointed him overseer of convict gangs in Sydney. In 1799 he was convicted of receiving stolen goods, and sentenced to 14 years on Norfolk Island; Hunter, however, considered that there had been a miscarriage of justice—due, it was alleged, to personal spite—and suspended the sentence until the evidence had been reviewed in England. There the matter was neglected until December 1801 when, after repeated reminders from Hunter, the home office granted Nichols a free pardon. He was released on 13 June 1802, became a shipowner, landowner, and assistant to the superintendent of customs, took sides against Bligh, and in April 1809 was authorized by Paterson to act as postmaster for the colony (see Posts and Telegraphs). In 1810 Macquarie continued him as postmaster and appointed him superintendent of convicts, a position which he resigned in 1814. He died on 8 November 1819.

Nicholson, Sir Charles (1808-1903), born at Bedale in Yorkshire on 23 November 1808, studied medicine at the university of Edinburgh (M.D., 1833; hon. D.C.L., Oxon., 1857; hon. LL.D., Cantab., 1868; hon. LL.D., Edin., 1886) and in 1834 came to New South Wales

to practise his profession. In 1843 he was returned to the legislative council for the Port Phillip district, and in 1848 and 1851 for the county of Argyle. From August 1844 to May 1846 he was chairman of committees, and speaker in May 1846-June 1848, May 1849-June 1851, and October 1851-February 1856. He was a nominee member of the first legislative council of Queensland, and became its first president, but resigned on 28 August 1860. Meanwhile he had become closely associated with the cause of higher education in the colonies. He took a prominent part in the founding of the university of Sydney, of which he was elected vice-provost in 1851, and delivered the inaugural address at the official opening on 11 October 1852. He was provost from 1854 to 1861 and chancellor in 1861-2; the office was the same, but its name was altered in 1861. During two visits to England he secured for the university a grant of arms from the college of heralds in 1857 and a royal charter in 1859. In 1857 he presented to the university its museum of Egyptian, Etruscan, Greek, and Roman antiquities, and the stained-glass western window in the Great Hall, and in 1867 established a medal and annual prize for Latin verse, from the accumulations of which a Nicholson scholarship for Latin was founded in 1924. In 1862 he settled in England, where he died on 8 November 1903, leaving to the university of Sydney a munificent bequest of books and manuscripts. (Kt. Bach., 1852; Baronet, 1859.)

Nicholson, WILLIAM (1816-1865), born at Lamplugh in Cumberland on 27 February 1816 and educated at Whitehaven, became clerk in a Liverpool fruit depot in 1836 and in 1841 migrated to Melbourne, where he set up as a grocer. His business prospered and he became a prominent citizen, helping in 1850 to found the Anti-transportation League of Australia, and in November of that year being chosen mayor of Melbourne. As Mayor he signed in July 1851 the announcement of the discovery of payable gold in Victoria. In October 1852 he was elected by North Bourke to the legislative council, and in 1853 was a member of the committee that drew up the Victorian constitution. In December 1855, when the first electoral bill under this constitution was being discussed in the council, Nicholson carried a resolution insisting on the use of the ballot; Haines, then premier, resigned; Nicholson was unable to form a new ministry (he does not seem to have tried very hard); Haines, returning to office, announced that he would disregard the resolution —and Nicholson, returning to the attack, forced him to accept it by successive amendments in committee (see BALLOT, VOTING BY). Nicholson then visited England, where he was welcomed in 1857-8 as 'the father of the ballot' by Cobden, Bright, and John Stuart Mill. Reaching Melbourne again in July 1858, he was in January 1859 sent to the legislative assembly by the Murray electorate and in August of the same year by Sandridge; in October he defeated the O'Shanassy ministry and took office himself, with James McCulloch as treasurer and James Service as minister for lands, but was ousted in November 1860 by Richard Heales (q.v.). In 1862 he joined O'Shanassy's second ministry, but without portfolio. In 1864 he became paralysed, and died at St. Kilda near Melbourne on 10 March 1865.

Nickel. See MINERALOGY.

Nickle, SIR ROBERT (1786-1855), was born at sea on 12 August 1786, received his education at Edinburgh, and entered the army in the Royal Durham Fencibles (ensign, 1801; lieutenant, 1802; captain, 1809; brevet-major, 1819; lieutenant-colonel, 1825; brevet-colonel, 1848; major-general, 1851). In 1806, while a lieutenant in the Connaught Rangers, he took part in the disastrous expedition against Buenos Aires, and on 2 July 1807 was severely wounded while leading a forlorn hope. Returning to England, he was sent to the Peninsula in March 1809, and took part in nine general actions—Talavera, Bussaco, Torres Vedras, Vitoria, Pyrenees, Nivelle, Nive, Orthez, and Toulouse (where he was again badly wounded). After the war he commanded the light company of the 88th. In June 1814 he sailed with his regiment to America, where he took part in the battle of Plattsburg and was wounded at the crossing of the Savannah River. In June 1830 he sailed to the West Indies with the 36th regiment and acted as governor from July 1832 to March 1833. In 1838 he served at the outbreak of the rebellion in Canada. In 1853 he was appointed commander of the forces in Australia, reached Sydney in 1854, and was stationed first at Sydney and later at Melbourne, where he had to deal with the goldfields disturbances at Ballarat. Arriving at the diggings just after Captain Thomas had captured the Eureka Stockade (q.v.), by his calm judgment and humane demeanour he restored peace and dispersed the rioters. His health having suffered through exposure, in 1855 he applied for leave to return to England, but died, while still awaiting permission, at his house at Jolimont (Melbourne) on 26 May. (K.H., 1838.) J.V.C.-B.

Nicotiana, a genus of the family Solanaceae, entirely American, with the exception of one somewhat variable species endemic in Australia. This is *N. suaveolens* (Native Tobacco), which ranges across the continent, but is chiefly

Native Tobacco.

found in the interior. It is an erect biennial herb, with white (or greenish) sweetly-scented tubular flowers; fruit a dry capsule. It grows luxuriantly on sandhills in the Riverina district of New South Wales, and in the early days the leaves were made into a sort of tobacco. Stock eat it readily when mixed with other herbage, although chemical investigation shows that, if eaten alone in quantity, it contains sufficient nicotine to poison them.

Nightjar. See FROGMOUTHS AND NIGHTJARS.

Nixon, FRANCIS RUSSELL (1803-1879), son of Robert Nixon of Foot's Cray in Kent, an early patron of the painter J. M. W. Turner, was born on 1 August 1803, and educated at Merchant Taylors' school and St. John's College, Oxford (B.A., 1827; M.A., 1841; D.D., 1842). After a period of parochial work in Kent, he was on 24 August 1842 consecrated in Westminster Abbey first bishop of Tasmania, and was enthroned in St. David's church at Hobart on 27 July 1843. His diocesan administration was not marked by any outstanding development of church work, but he was a good musician, a pleasing artist, and an eloquent preacher. To enable him to visit the outlying parts of his diocese he secured a 10-ton yacht; in 1849 four convicts ran away with it and, after a remarkable voyage across the Pacific, reached California. Their leader apologized by letter to the bishop for the theft, explaining that only necessity had driven him and his companions to it. In 1863 Nixon resigned the bishopric, returned to England and, in recognition of his work in Tasmania, was appointed in 1864 to a rectory in Yorkshire; this, however, he held for a year only. He died on 7 April 1879 at his home on Lago Maggiore in Italy. Among his many published works are: *Lectures on the Church Catechism* (London, 1860); *Transportation: a Communication to Earl Grey* (Launceston, 1848); *The Cruise of the Beacon* (London, 1857); *Twelve Views in Adelaide* (Adelaide, 1845).

Noble, MONTAGU ALFRED, born in Sydney on 28 January 1873, first played for his colony in 1894, and in 1898 made his appearance in test cricket in the first Melbourne match against Stoddart's eleven. He took part in 39 test matches consecutively, making his last appearance at the Oval in August 1909 as captain of that year's Australian team. He won fame first as a bowler, heading the Australian test averages in 1898 with an average of 20.29, and his bowling remained throughout his career a great asset to the Australian teams; he bowled 1169 overs in all, taking 115 wickets (an average of 24.78), a record only excelled by Trumble's 141 wickets for an average of 20.88 (Giffen bowled more overs for fewer wickets, and Spofforth and Turner had better averages for considerably fewer overs). His batting was less evenly excellent; in 1899 and in 1903-4 he ranked second (to Hill in the one case and Trumper in the other), but in other seasons was much lower down the list. In 68 test-match innings he scored 1905 runs, an average of 30.72. Outside test cricket he has been a great run-getter in Sheffield Shield matches, having an average of 65.81—4976 runs in all; he also took 169 wickets, at an average of 22.01. His bowling was right-hand with medium pace, deceptive flight and swerve, and a break from the off. See CRICKET.

Nonda Tree. See PARINARIUM.

Norfolk Island lies in the western Pacific in lat. 29° 4′ S. and 167° 58′ E.; it is about five miles long and three miles wide, and has an area of a little over 13 square miles. The coast-line, except on the south-west, consists of inaccessible cliffs washed by a heavy surf; the surface is mainly tableland, from which Mount Cook rises to a height of 1000 feet. The island was discovered by Captain Cook on 10 October 1774 and named by him 'in honour of the noble family of Howard.' The island was uninhabited, and Cook and his men were probably the first who ever landed on it. Cook noticed that the flora was similar to that of New Zealand. The most important tree is the spruce-pine, an *Araucaria* intermediate between the pines of New Zealand and those he had seen in the New Hebrides. The history of the island since its discovery falls into three periods, with an interval between the first and the second. From 1788 to 1808 it was a branch of the penal settlement at Sydney. It was then left unoccupied till 1825, when it was set aside mainly for the reception of 'colonially convicted' criminals (i.e. those who incurred fresh punishment for misdemeanours committed in New South Wales). In 1855 the penal settlement was abolished, and in the following year the inhabitants of Pitcairn Island (see BOUNTY, MUTINY OF THE) were transferred to the island.

First Period (*1785-1808*).—Early in 1785, about the time when the Matra-Young proposals for the colonization of Botany Bay were being discussed by the British government, speculators applied to the East India Company for leave to establish on Norfolk Island a factory from which the Indian marine could be supplied with cordage; they suggested that the island might also become a centre of the Alaskan fur-trade, a half-way house to China, and an outpost against the Pacific possessions of Spain. Alexander Dalrymple, the company's hydrographer, in July of that year condemned the project vigorously, alleging that its real object was to establish a smuggling trade-centre in the company's domain—which theoretically extended from the eastern coast of Africa to the western coast of America. It is probable that Dalrymple's chief desire was to attack indirectly the proposals for settling in New Holland. Nothing came of the speculators' application; but the British government instructed Phillip on 25 April 1787 to settle Norfolk Island as soon as possible after reaching Botany Bay.

On 15 February 1788 Phillip despatched the *Supply* from Sydney under Lieutenant Henry Lidgbird Ball, with Lieutenant P. G. King (superintendent and commandant), James Cunningham (master's mate), Thomas Jamison (surgeon's first mate), six other free men, and nine male and six female convicts—23 persons in all. Six months' provisions and stores were sent with the party, and a four-oared boat was supplied for the use of the officials, who had instructions that no boat over 20 feet in length was to be built on the island. No ships were to call, unless in distress, without a permit, and any vessel driven ashore was to be destroyed. Their live stock consisted of six ewes, three sows, a goat, two boars, four hens and a cock, three ducks and a drake. King had instructions to set about the immediate cultivation of flax, corn, cotton, and other plants, the seed of which was supplied; great expectations had

been formed with regard to cotton and flax, but nothing came of them. On her way the *Supply* discovered Lord Howe Island (q.v.) and on 29 February 1788 the north-western point of Norfolk Island, named by King Point Howe, was sighted. Two small islands off the south-eastern shore were named Phillip and Nepean isles; King also named Ball Bay and Anson Bay, Point Hunter, and Duncombe Bay. Late in the afternoon of 2 March a landing was made on a cluster of rocks near the Cascades, which King named Cook's Rocks. On 4 March King climbed and named Mount Pitt; on the 6th, as the weather had moderated, the ship was brought round to Sydney Bay, and by the 8th every one had disembarked and the *Supply* sailed for Port Jackson. By 2 April a storehouse had been built, and King began to clear the north-eastern side of the hill at the head of Sydney Bay, which he named Mount George. On 10 March the dangerous element among the convicts asserted itself. King ordered salt provisions to be husbanded whenever fish or turtle could be obtained, in case the ship did not return with fresh supplies. One of the convicts endeavoured to stir up a mutiny because of this, but King gave him 40 lashes—a wise action, for, though the *Supply* came in sight on 16 July she could not land stores until 6 August. On 13 October the *Golden Grove* transport brought more stores, 21 male and 11 female convicts, a guard of marines, two gardeners (seamen of the *Sirius*), and Stephen Donovan, a midshipman in charge of a boat's crew from the same ship. On 23 November another plot to seize the island was discovered; King put the ringleaders in irons, and gave them from 30 to 50 lashes each. Thenceforward till 1790 the island was quiet, and crops were grown successfully, but not in sufficient quantity to make the settlers independent of supplies from Sydney; bad seasons in New South Wales prevented the regular arrival of storeships, and at the beginning of 1790 famine stared the settlers in the face. Early in March, however, the *Sirius* and *Supply* arrived with supplies, bringing Major Ross to relieve King, who was to return to Sydney and then to England to make a report. The *Sirius* (q.v.) was subsequently wrecked. As soon as the disaster occurred Ross declared martial law, and all private property was placed under lock and key in the public store.

On 24 March King boarded the *Supply* and sailed with news of the disaster to Sydney. At the moment there were on the island free persons, 90; belonging to the *Sirius*, 80; male convicts, 191; female convicts, 100; children, 37; total 498. (The first child born on the island was born on 8 January 1789 and baptized Norfolk.) The quantity of grain and live stock was:—wheat, 250 to 300 bushels; potatoes, 1 acre ready to dig in May; barley, 6 bushels; maize, 130 to 160 bushels; hogs, 44; 3 goats; 1 ewe; a quantity of poultry; and some other stock belonging to individuals. Seldom has a small community gone through such an anxious time as now came to the islanders. Weeks grew into months, and no ship was sighted. The *Sirius* went to pieces on New Year's Day 1791, every useful article having been saved from her. The food ration was gradually reduced. The prisoners often ate a week's allowance at a meal; in consequence some died of starvation, others were executed for thieving from the general store. Fortunately in April Mount Pitt was crowded with birds—the 'mutton-birds' of Tasmania—which went to sea during the day but returned to the mountain to burrow nests during the night; between 2000 and 3000 were killed every night, and the supply did not diminish until July. On 7 August 1790 the *Justinian* and *Surprize* storeships arrived from Port Jackson. The delay had been caused by the loss of the *Guardian*, which had left Sydney almost as badly off as Norfolk Island (see RIOU).

In the meantime King arrived in England on 5 January 1791 and learned that a commission appointing him lieutenant-governor of the island had been sent to Sydney; he therefore returned in the *Gorgon* and reached Norfolk Island on 4 November to find it full of discontent. On 8 January 1791 Ross had issued an order—known as the 'one-acre plan'—by which the convicts were given Friday and Saturday to cultivate a certain proportion of land for themselves, their rations from the public stores to be reduced in proportion as the produce of the land became available to them. The idea was a good one, but Ross did not allow time enough to get it into working order, and King had to modify the system considerably. In 1792 two Maoris, who had been kidnapped to teach Australian settlers how to grow flax, were sent on to Norfolk Island from Sydney. King kept them six months and then sent them home in the *Britannia* storeship, accompanying them himself because of 'the sacred duty that devolves upon Englishmen of keeping faith with the native races, and the desire to see for myself what can be done towards colonising New Zealand.' During his absence the soldiers fraternized with the convicts, and in due course quarrelled; a time-expired prisoner (an aggrieved husband) struck a soldier; King on his return treated the offender mildly, and the troops in their resentment became as dangerous as the prisoners. After a theatrical performance on 18 January 1794 the soldiers assaulted the civilians; some soldiers ran to the barracks, donned their side-arms, and returned threatening reprisals; King had one arrested, and promptly marched the detachment to a distant part of the island under pretence of collecting wild fowl, at the same time forming a local militia of 44 ex-marines and seamen. The government schooner *Francis* arriving just then, King sent ten soldiers and some civilians to Sydney to attend a court of enquiry, which found that the conduct of the soldiers had been 'reprehensible' but recommended them to their commanding officer's clemency. Grose, then in charge of the settlement, ordered King to disband his militia, and complained officially of King's actions, but the colonial office refused to rebuke him except for going to New Zealand without Grose's permission.

Up till now the island had no criminal court. On 24 March 1796 the *Supply* brought King a patent for establishing such a court to try offenders on the spot—a wise step, because the knowledge that summary justice could be handed out tended to keep the more vicious convicts fairly quiet. At the first sittings of the court, in June, a convict was sentenced to death, and his two accomplices to hard labour on Phillip Island, for burglary accompanied by brutal violence. In 1796 King obtained leave of absence on the ground of ill-health, and was relieved by Captain Townson, who was succeeded in November 1799 by Captain Rowley (both of the New South Wales Corps). On 26 July 1800 Major Foveaux was appointed lieutenant-governor. During this period the island was

comparatively tranquil and becoming prosperous. When King left, wheat was being raised extensively, and the population was on the increase; in 1798 a small ship was built, and by 1800 the raising of pigs and curing of pork had become a small industry, but flax-growing proved a failure.

Religion was encouraged spasmodically. Richard Johnson accompanied Philip Gidley King in 1791, and was 'very usefull in marrying, christening, &c.,' but returned to Sydney at the end of the year. In 1793 James Bain, chaplain to the New South Wales Corps, visited the island, but was recalled in March 1794; his place was taken by the provost-marshal, Fane Edge, who carried out 'such parts of the offices of chaplain of this island as he conceived himself authorized to undertake,' at least up to 1798. Marriage and baptism were not among these parts, for in June 1795 Samuel Marsden was sent over to perform those ceremonies where needed; his visits were probably repeated at intervals, for no resident clergyman reached the island until 1801. Charles Haddock, who was appointed to the post by the Society for the Propagation of the Gospel in October 1798, drew part of his salary in advance but did not leave England; in November 1800 his appointment was cancelled. In 1801 King (by this time governor of New South Wales), weary of waiting, emancipated Henry Fulton (q.v.), and sent him to Norfolk Island as resident chaplain, first at 5s. per day, then at 7s. 6d., and (when his action was confirmed by the colonial office) at £96 per annum. Education had been undertaken earlier. In 1792 Thomas Maequeen, previously so employed in England, obtained by good conduct the appointment of schoolmaster; Susannah Hunt at the same time acted as schoolmistress to the girls, and from 1797 onwards each received £10 per annum from the Society for the Propagation of the Gospel.

Foveaux's rule was stern, but conditions required that it should be so. Soon after his arrival he was faced with mutiny (14 December 1800) and only by severe measures was able to subdue it. His successor, Captain Piper, (8 August 1804) seems to have been more lenient towards the better-disposed convicts.

On 24 June 1803 Lord Hobart instructed King that Norfolk Island was to be abandoned and the settlement removed to Port Dalrymple. King ordered Foveaux to prepare a list of free settlers who would volunteer to move in return for a free passage for themselves and their belongings, four acres in Tasmania for every acre they had cultivated at Norfolk Island, and rations and the labour of two convicts for a year after arrival. Out of 180 occupiers of land 40 volunteered, stipulating that they should not be removed till their crops were reaped; but on the arrival of the *Integrity* on 4 August 1804 all but ten backed out of the bargain. King then ordered the establishment to be reduced, and most of the convicts, with half the military detachment, were withdrawn. By the end of 1805 about 250 people had gone, leaving 700 still on the island. Piper induced some free men to try the new colony, and five took up land near York Town in Tasmania, but shortly afterwards shifted to Longford on the South Esk. In December 1805 the *Sydney* brought over George Guest, the first Norfolk Island settler on the Derwent. This dilatory removal did not suit the colonial office, which in December peremptorily ordered Bligh to abandon the island at once; settlers might be allowed monetary compensation not exceeding £1000, and grants in the proportion of two acres for each acre of cultivated land given up; houses were to be erected for them of equal value to those left behind, and convict labour was to be granted in proportion to the value of their estates. Bligh gave them the choice between Port Dalrymple and the Derwent; most chose the latter, some settling at Sandy Bay near Hobart, others at an inland village which they called New Norfolk. Bligh, and Johnston after the mutiny, now set to work in earnest to deport the islanders, and by 2 October 1808 the *Lady Nelson*, the *Porpoise*, the *Estramina*, and the *City of Edinburgh* had landed in Tasmania 202 free settlers, 109 women, 220 children, and 23 male prisoners. For some time after landing they were in great distress owing to bad seasons, their own improvident habits, and other causes. Even then the island was not altogether abandoned, a small detachment of soldiers and a few free settlers and convicts remaining; but within two or three years these were withdrawn, and from 1813 onwards the place was unvisited and unoccupied save by an occasional trader or whaler.

Second Period (*1825-1856*).—In 1824 the colonial office, in pursuance of a policy of segregation recommended by Bigge, determined to revive the station on Norfolk Island as a place of banishment for the worst type of convict—'Capital respites,' wrote Brisbane, 'and other higher class of offences. I could wish it to be understood that the felon, who is sent there, is for ever excluded from all hope of return.' On 6 June 1825 Captain Turton with 34 troops, 6 women and children, and 57 convicts reoccupied the station, which then consisted of totally ruined buildings with innumerable pigs and goats living in them. Major J. T. Morisset, who had been commandant at Newcastle and Bathurst, was made commandant with both civil and military powers, and Darling in 1827 decided the character of the penal settlement by withdrawing all women from the island—'My object was to hold out that Settlement as a place of the extremest punishment, short of Death.' In this he succeeded. For more than twenty years Norfolk Island was persistently described by every visitor in terms of which 'hell' was the mildest. Attempts have been made to cast the responsibility for this on the officials in charge. They were, no doubt, severe disciplinarians, and some of them over-severe; but their conduct was an almost negligible factor in the situation created by the deliberate orders of the British authorities. Two disinterested witnesses, James Backhouse and George Washington Walker, who visited Norfolk Island in 1837-8, testified that the officials were at any rate moderately humane, but had to deal with very bad characters, to whom at times they were compelled to administer severe punishment. Under Morisset the notorious Knatchbull, afterwards hanged for a brutal murder in Sydney, was a ringleader in a serious mutiny. The whole history, indeed, of the island's second period is a series of mutinies. In 1833-4 several prisoners succeeded in escaping from custody. On 21 June 1842, when the brig *Governor Phillip* was leaving the island with convicts whose sentences had expired, the convict crew of the settlement boat boarded the brig, overpowered the sergeant of the guard, and battened the hatch over the captain's cabin and soldiers' quarters; but for the prompt action of the captain, who broke through the partition and liberated

the soldiers after shooting the convict at the helm, they would have taken the brig and escaped in her. The ringleaders were sentenced to death. Incidents of this kind naturally made the officials severe, but the island was always in a pitiable condition, and attempts at reform were frustrated by the constant arrival of new prisoners from England.

Morisset was followed by Major Anderson, and he by Alexander Maconochie (q.v.), who, being a lenient man, reaped no small harvest of trouble; there were more mutinies and more outrages in his time than in any other period. In 1844 the island was annexed to Tasmania, and Maconochie was succeeded by Major Childs, whose failure was even worse; it was not until John Price took charge in 1848 that anything like discipline was restored. But the place was not improved by discipline. An officer in 1847 described it as by nature 'a paradise endowed with choicest gifts of climate, scenery and vegetable production; by art, society or policy, a hell, disfigured by crime, loathsome vice and misery . . . the clanking of irons, the dull echo of the lash, with execrations both loud and deep, make men's flesh creep and fill their minds with horror and despondency.' Officials and judges continually asserted that the system, so far from reducing the number of criminals, really increased it. Yet the island was no worse than similar places in England and in the French penal settlements, and the officials on whom so much odium has been cast by Marcus Clarke and other writers were normal human beings, very often carrying out their duties (considering the times) in a remarkably humane manner.

The number of prisoners during this period varied from 1600 to 2000; most were 'doubly convicted' felons from New South Wales or Tasmania, but prisoners of all grades were sent from England.

Third Period (from 1856 onward).—On 15 December 1852 the colonial office asked Governor Denison to report on a plan for the removal of the convict settlement from Norfolk Island and for its occupation by the Pitcairn Islanders (see BOUNTY, MUTINY OF); this plan was favoured both by the British consul at Raiatea in the Society group, and by Admiral Fairfax Moresby (see MORESBY, JOHN), who was in command on the Pacific station and took a great interest in Pitcairn. Early in 1854 instructions were given for the removal of the prisoners and by 7 May 1856 all had been shipped away; the island was left in charge of three caretakers (convicts), and in June of that year was resurveyed by Captain H. M. Denham in H.M.S. *Herald*. On 3 May the *Morayshire*, a hired merchantman, left Pitcairn with 194 passengers —40 adult males, 47 adult females, 54 boys, and 53 girls—and reached Norfolk Island on 8 June. The Pitcairners brought their belongings with them, and Sir William Denison, by authority of the British government, left for their use 2000 sheep, 450 head of cattle, about 500 pigs, 20 horses, and large quantities of preserved foods and grain. By an order-in-council of 1856 the island was separated from Tasmania, created a distinct settlement, and placed till further orders under the governor for the time being of New South Wales. The governor was given power to make all appointments, laws (subject to imperial orders and regulations), and grants of land; all laws, ordinances, and regulations, civil and ecclesiastical, then applicable to the island, remained in force, subject to alterations rendered necessary by the change of government. The incomers were allowed to use the government buildings, and each family was given an allotment of about 50 acres, but the right of ownership was based on a grant from the crown, and land was held at its discretion. These restrictions were made to protect the Pitcairners from parting too readily with their property. Much trouble has ensued, the community holding that the lands were held in absolute freehold, the government maintaining the literal interpretation of the original terms.

In 1859 ten new colonists were sent out by the emigration commissioners in the *Palmyra*— Thomas Rossiter, who had been master of an industrial school in Hertfordshire, with a family of four, James Darve, a miller, smith, and wheelwright, with a family of three, and H. J. Blinman, a mason and plasterer; Rossiter was appointed schoolmaster and storekeeper. In spite of all the kindly treatment some of the Pitcairners longed for their old home, and in December 1858 two families of Youngs (16 persons in all) grew homesick and returned by the schooner *Mary Anne* to Pitcairn. Five years later (in December 1863) three other families —Youngs, Christians, and a Buffet, altogether 30 persons—followed their example. By 1870 one of the Quintals, a son and daughter of Adams, and a daughter of Mills were the only still living children of the mutineers; there were 32 of the second generation, with their offspring. In recent years the population has been increased by arrivals from Australia and New Zealand.

The government of the island, apart from the order-in-council mentioned above, retained until 1895 the simple form which the Pitcairners had invented for their former home. Governor Loftus in 1884 commissioned Henry Wilkinson to collect data for the framing of suitable laws and to supply information regarding island affairs generally. His report was furnished in October 1885, when the British government offered to hand over the island to New South Wales. On 14 November 1896 Lord Hampden, then governor of New South Wales, visited the island by order of the British government, and by orders-in-council dated 15 January 1897 and 18 October 1900 its government was vested solely in the governor of New South Wales with the advice of his ministry. On 14 August 1902 it was officially notified that Sir Harry Rawson had taken over the administration of affairs, and that the premier of the State for the time being would exercise all ministerial functions in that connection. The governor was expected to visit the island at least once during his term of office.

Authority was from 1855 onwards vested in the chief magistrate, who must reside on the island; but the power of alienating, leasing, and authorizing occupation of lands was exercised by the governor of New South Wales alone. The chief magistrate could suspend an officer and appoint another temporarily in his place, and his court had jurisdiction to punish all crimes and offences (except crimes punishable by death), to adjudge all civil pleas whatsoever, irrespective of the amount claimed or in issue, and to grant probate, etc., in connection with the estates of persons dying possessed of real or personal property in the island. Till 1895 the chief magistrate was elected annually by the residents from among their own number, but in 1896 Colonel Spalding was appointed by the governor; he was succeeded by Charles McArthur King, a grandson

of Governor King, in 1898-1903, and he by Captain Walton Drake, R.N. Drake retired in February 1907, and his successor (Captain S. E. Elliott, R.N.) remained in office till 1 July 1914, when the Commonwealth government took over the island. It is now administered by the department of home and territories through an administrator and chief magistrate.

In December 1925 the population of the island numbered 747. The live stock consisted of 1954 cattle, 663 horses, 144 sheep, 208 pigs, and 5846 poultry. Subtropical fruits thrive well; in 1925 5942 bushels of oranges, 271,600 dozen bananas, and 18,320 lb. of coffee were grown, besides passion-fruit, pineapples, and the produce of thousands of wild lemon and guava shrubs. The export trade, however, is insignificant—in the five years 1921-5 the value of imports averaged £91,659 and that of exports only £28,281. Education is free and compulsory up to the age of 15; it is modelled on the New South Wales system, and administered by the New South Wales department of education at the island's expense. The liquor traffic is prohibited.

Administrators of Norfolk Island, 1788-1853 with date they took charge.

Lieutenant Philip Gidley King	6 March 1788
Major Robert Ross	24 March 1790
Lieutenant Philip Gidley King	4 November 1791
Captain John Townson	22 October 1796
Captain Thomas Rowley	12 November 1799
Major Joseph Foveaux	29 June 1800
Captain John Piper	9 September 1804
Lieutenant T. A. Crane	10 April 1810
. . . . .	. . . . .
Major R. Turton	4 June 1825
Captain Vance Y. Donaldson	17 March 1826
Captain Thomas Edward Wright	19 August 1827
Captain Robert Hunt	26 November 1828
Captain Joseph Wakefield	17 February 1829
Lieutenant-colonel James T. Morisset	26 May 1829
Captain Foster Fyans (acting)	1 January 1834
Major James Anderson	17 April 1834
Major Thomas Bunbury	3 April 1839
Major Ryan	27 September 1839
Captain Alexander Maconochie	1 March 1840
Major Joseph Childs	7 February 1844
John Price	6 August 1846

J.V.C.-B.

Norman, Sir Henry Wylie (1826-1904), born in London on 2 December 1826, in 1842 joined his father in Calcutta, and two years later joined the 1st Bengal native infantry (ensign, 1844; lieutenant, 1847; captain, 1860; brevet-major, 1860; brevet-colonel, 1860; major-general, 1869; lieutenant-general, 1877; general, 1882; field-marshal, 1902). He took part in the Sikh war of 1848-9 and in actions on the Peshawur front, in 1853 became deputy assistant adjutant-general, served throughout the Indian mutiny with marked distinction, and in 1858 published the *Narrative of the Campaign of the Delhi Army.* In 1859 he returned to England on leave and was appointed assistant military secretary to the Duke of Cambridge, but in 1861 was ordered back to India as first military secretary to the government to assist in the reorganization of the army. Thereafter his energies were absorbed in administrative work. In 1870-7 he was a member of the governor-general's council, and in 1878 was transferred to London to be a member of the council of India. In 1883-6 he was governor of Jamaica, and in 1889-95 of Queensland, where no more popular governor had ever held office. In 1893 he was offered the governor-generalship of India, but ill-health made acceptance impossible. In December 1896 he was appointed chairman of a royal commission on sugar-growing in the West Indies, and in 1901 became governor of the Chelsea military hospital at London. He was also a member of the royal commission of 1903 on the South African war. He died at Chelsea on 26 October 1904. (C.B., 1859; K.C.B., 1873; C.I.E., 1878; G.C.M.G., 1887; G.C.B., 1887.)

Normanby, Marquess of. George Augustus Constantine Phipps (1819-1890), second marquess of Normanby, born at Whitby in Yorkshire on 23 July 1819, in 1838 joined the army as ensign in the guards, but resigned in 1847. In 1844 he was appointed deputy lieutenant of Yorkshire. In 1847-51 and 1852-8 he was liberal member for Scarborough in the house of commons; meanwhile in 1851 he had been appointed comptroller, and in 1853 treasurer, of the Queen's household. In 1858 he became lieutenant-governor of Nova Scotia, but resigned in 1863 on succeeding to the marquisate. From 1871 to 1874 he was governor of Queensland, and was then transferred to New Zealand (1874-9) where in 1877-9 he found himself at odds with the premier, Sir George Grey, on the question of appointments to the legislative council. From 1879 to 1884 he was governor of Victoria and during this term of administration was 'politically inconspicuous;' his restricted hospitality was somewhat resented in Melbourne society, but he knew his business as governor too well to rouse animosities. On 18 April 1884 he left Victoria for England, and retired from public service. He died in London on 3 April 1890. (P.C., 1851; K.C.M.G., 1874; G.C.M.G., 1877; G.C.B., 1885.)

North Australia. See Gladstone Colony.

Northern Territory, The. The central section of the northern half of Australia, separated from Western Australia by the 129th meridian, from Queensland by the 138th, and from South Australia by the 26th parallel of latitude. The greater part of the Territory is within the torrid zone, but a strip 2½ degrees wide lies outside the tropics. The low, flat coast-line seldom reaches a height of 100 feet; sandy beaches and mud-flats, thickly fringed with mangroves, are broken by occasional headlands of sandstone, marl, and ironstone. Inland the country is generally destitute of landmarks. From the coast southwards there is a general rise to the vicinity of 17° or 18° S. lat., where higher land forms a watershed between sea-flowing rivers and those of the interior systems. Towards the centre of the continent there is a wide area of considerable elevation, and several mountain ranges, generally with an east-west trend. There are two main climatic divisions—the wet season (November to April) and the dry (from May to October), with regular and uniform changes of weather. Nearly the whole of the rainfall occurs in the summer months. On the coast the rainfall is copious—up to 60 inches annually—but lessens to five or six in the south. The mean temperature during the wet season is about 85° Fahr., during the dry period about 75°. Thermometer readings vary from 56° in winter to 100° in summer. Frosts have been known in the valley of the upper Roper.

The ordinary Australian fauna—marsupials, birds, crocodiles, freshwater tortoises, snakes (mostly non-venomous), and frogs—abound; there are many varieties of freshwater fish and littoral mollusca, and butterflies and beetles are strongly represented. The termite (q.v.)

is the principal pest, but mosquitoes and sandflies are also troublesome, especially in the wet season. Some native fauna are protected by law, and domesticated animals have been introduced. Buffaloes (q.v.) formerly roamed in large herds, but indiscriminate shooting has recently thinned their ranks. The vegetation is North Australian in type, but a number of forms belong to the Malayan and Oceanic regions (see ZOOGEOGRAPHY). The timber-trees are of no great commercial value, but in the coastal regions tropical vegetation grows luxuriantly down to the water's edge. On the wide expanses of plain country in the interior there is little vegetation.

The discovery of Arnhem Land in 1623 by the Dutch, and of other coastal areas of the Territory afterwards, is narrated under AUSTRALIA, DISCOVERY OF, and the coastal explorations of Flinders (1802-3) and Phillip Parker King (1819-20) under EXPLORATION BY SEA. King on his return to England strongly advised the British government to occupy a port—preferably Port Essington—in northern Australia, and later on in the same year (1823) William Barnes, master of a vessel trading in the Dutch islands, suggested to the colonial office a settlement in the Gulf of Carpentaria. In December a committee of merchants trading with the East Indies, who had access to King's report, asked for the establishment of a military and commercial settlement at Port Essington, mainly in order to give British traders a base in the Archipelago independent of the Dutch, whose import and export duties were strongly preferential against all non-Dutch merchants. Earl Bathurst, then secretary for the colonies, was not much impressed by Barnes, but acceded to the request of the merchants, and on 17 February 1824 ordered the despatch of a warship to the north-western coast of Australia to take possession of 'that part of the said Coast contained between the Western shore of Bathurst Island and the Eastern side of Cobourg Peninsula, including the whole of Bathurst and Melville Islands, and the said Peninsula.' Captain J. J. G. Bremer (q.v.) in H.M.S. *Tamar* was sent first to Sydney to pick up troops and stores. On 24 August 1824 the *Tamar* with a detachment of marines, the transport *Countess of Harcourt*, and the government schooner *Lady Nelson* (60 tons), left Port Jackson for the north; the occupying party consisted of two officers and 24 men of the 3rd regiment, a medical officer, a commissariat officer, two storekeepers, and 44 convicts. As the proposed settlement was outside the bounds of New South Wales, convicts could not be forced to go there, but the 44 volunteered. The *Lady Nelson* was ordered to inaugurate trade with the Malay coast. On 20 September the party landed at Port Essington, and Bremer took formal possession of the northern coast of Australia between 129° and 135° E. long. However, no fresh water could be found, so three days later the place was abandoned and the party proceeded to Melville Island. On 24 September Bremer anchored off Melville Island in Cockburn Sound, discovered a supply of fresh water, and decided to form the settlement there. Formal possession was taken on 26 September, the troops and convicts landed, and the erection of buildings commenced. On 1 October the construction of Fort Dundas was begun, and on 21 October (the anniversary of the battle of Trafalgar) the colours were hoisted on the fort and a royal salute from two 9-pounder guns and a 12-pounder was fired. Bremer next visited Bathurst Island, and on 13 November, leaving 30 marines under 2nd-lieutenant Charles Cartwright Williamson, sailed for India. The *Lady Nelson* was left to convey stock and supplies from the islands to the settlement. No sooner had the *Tamar* sailed than trouble began with the natives. The *Lady Nelson* was captured by them off Babar Island (200 miles east of Timor) and her crew was murdered; and when at the beginning of 1825 the brig *Stedcombe* under William Barnes landed supplies and sailed under charter to procure buffaloes from Timor, she was captured by pirates off the coast of Timor Laut and burnt. Barnes had stayed at Melville Island, and thus escaped the fate of the crew—who were butchered, with the exception of two boys (Edwards and Forbes). Forbes was rescued in April 1839 by Captain Watson in the *Essington*, Edwards having died about four years previously (see WILD WHITE MEN). Disease soon broke out in the settlement, and before long it became clear that Melville Island was an undesirable town-site. On 19 September 1826 a detachment of the 57th regiment relieved the garrison, arriving in the cutter *Mermaid* and the schooner *Isabella*. At this period the population was 115 males (54 of them convicts), 6 females, and 14 members of ships' crews; the stock consisted of 16 cattle, 23 sheep and lambs, 54 swine, and 16 buffaloes from Timor. Fifty-two acres of land were under cultivation.

So unsatisfactory were the reports of Melville Island that the colonial office decided in 1826 to form a settlement at Raffles Bay, east of Port Essington. The founding of the new settlement was entrusted to Captain James Stirling (q.v.) of H.M.S. *Success*, who left Sydney on 19 May 1827 accompanied by three transports conveying a detachment of the 39th regiment under command of Captain Smyth, and a working-party of convicts. Stirling reached Raffles Bay on 17 June, and placed his settlement on the eastern side of the bay in the vicinity of some freshwater pools. As Melville Island was useless, the troops and convicts were removed to the new site in 1828. On 16 March 1828 the brig *Governor Phillip* left Sydney with Captain H. R. Hartley and a detachment of the 57th regiment to relieve Major Campbell, and on 24 April Captain Smyth was succeeded at Raffles Bay by Lieutenant Sleeman of the 39th. The troops relieved, with four marines and four convicts, returned in the *Governor Phillip* to Sydney. On 15 July Captain Collett Barker (q.v.), with a detachment of the 39th regiment, sailed in the *Phoenix* for Raffles Bay. That settlement, however, was short-lived, for in April 1827 Stirling had reported so favourably on a site at Swan River in Western Australia, that it was decided to form the main settlement there, maintaining merely a trading-station at Raffles Bay. On 28 August 1830 the troops and convicts embarked; on the following day the settlement at Raffles Bay was finally abandoned, in spite of Barker's insistence that it should be retained.

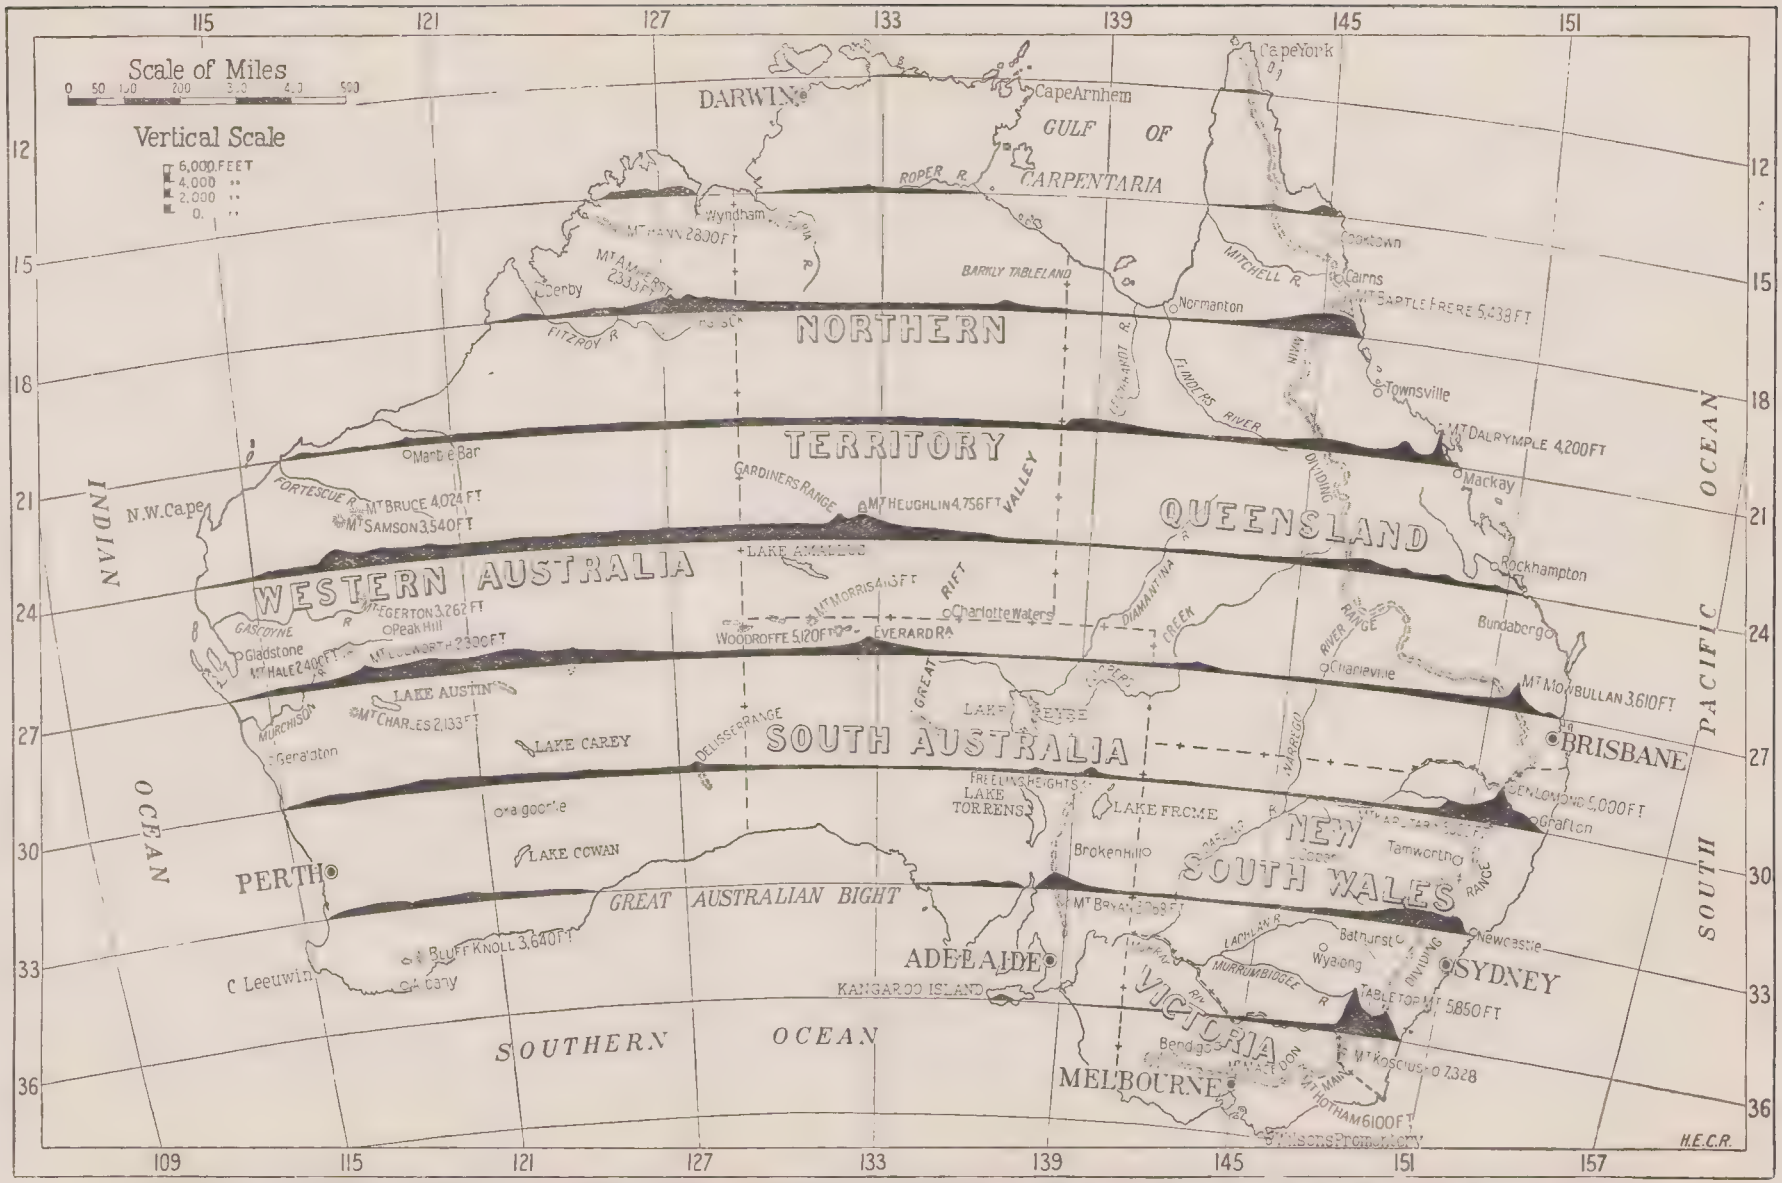
In 1837, rumours that a French expedition was fitting out at Toulon to take possession of some port on the northern coast of Australia reached the British government, and Lord Glenelg ordered another expedition to revisit and re-annex Port Essington. Bremer in H.M.S. *Alligator*, with a detachment of marines under Captain J. McArthur, accompanied by H.M. brig *Britomart* under Lieutenant Owen Stanley, sailed from Plymouth at the end of February 1838; the *Alligator* was disabled in

a heavy gale and was compelled to return. Sailing again on 10 March, she overtook the *Britomart* at Teneriffe, and both vessels reached Sydney on 21 July and refitted for the voyage to Port Essington. Accompanied by a hired transport, the *Orontes*, they sailed again on 17 September, on 20 October reached Cape York (where Bremer landed and took possession of the territory), and on 26 October arrived at Port Essington and anchored in Barrow Bay. A site (now occupied by the town of Victoria) was soon chosen, the troops landed, and the erection of barracks, fortifications, and stores at once commenced. Early in 1839 aborigines informed Bremer that two ships were lying at Raffles Bay, and Lieutenant Stewart was despatched in an open boat to investigate. He found two French ships anchored near Fort Wellington, and the French flag flying over 'two or three' of the abandoned tents on the shore. The vessels were the corvettes *Astrolabe* and *Zelée* under Commodore Dumont d'Urville; they had left Toulon six months ahead of the *Alligator* and her consort, and, when discovered, were surveying the coasts in the vicinity of Bowen Strait. Bremer invited Dumont d'Urville to the settlement, and on 6 April 1839 the ships anchored off Record Point, where they remained three days, afterwards sailing towards the Aru Islands (see EXPLORATION, FRENCH). On 9 July 1839 H.M.S. *Beagle* under Captain J. Lort Stokes discovered the Adelaide River; in October she entered the Victoria River, and a survey was conducted by Stokes and Wickham, who reported favourably upon it.

In 1843 the colonial and land emigration commissioners reported unfavourably on Port Essington, complaining that there was no trade with the Malays who visited the port; that it had been used only by the crew of one shipwrecked vessel; that it was out of the track of passing ships; and that the cost of its upkeep (which up to January 1842 amounted to £16,021) was out of all proportion to its value. It was suggested that the port might be useful as a coaling-station in the event of the establishment of steam communication between Singapore and Australia via Torres Straits; as no steps were taken to establish this service, the admiralty on 6 June 1849 ordered the abandonment of the settlement, and stated that the government would not incur the expense of establishing and maintaining a suggested settlement at Cape York. As a result of this order a select committee of the New South Wales legislative council under the chairmanship of George R. Nichols reported in 1850 against forming a settlement at Cape York or in its immediate neighbourhood. In December 1849 Port Essington was abandoned for the second time, the buildings were destroyed, and the settlers removed to Sydney in H.M.S. *Meander*.

In 1860 A. C. Gregory (q.v.), whose explorations in 1855-6 had disclosed valuable tracts of land in northern Australia, proposed that Queensland should annex a large area south of the Gulf of Carpentaria, and that the rest of northern Australia as far west as the De Grey River should be formed into a new (probably penal) settlement of Albert. The colonial office, just then anxious to relieve itself of as much responsibility as possible, willingly agreed on condition that Queensland should take temporary charge of Albert also. But in 1860-2 South Australia was greatly interested in the northern regions, to which McDouall Stuart was energetically pushing his way across the continent. Since, therefore, Queensland did not want the responsibility of a huge western extension, while South Australia did not want another colony interfering with her hinterland, and nobody wanted to administer the north-western deserts (as they were then considered), in 1863 a compromise satisfactory to every one was reached; Queensland obtained her extension to 138° E. long., the north-west was left in the chaos nominally administered from Perth, and on 16 July the crown annexed to South Australia 'until We think fit to make other disposition thereof, the Territory now known as the Northern Territory.' This added to South Australia—whose name at once became a paradox—523,620 square miles of territory, which the authorities at Adelaide forthwith proceeded to colonize. It was proposed to lay out a town in allotments of half an acre, and to survey country sections of a minimum area of 160 acres; land-orders were to be issued for a total of 250,000 acres of country land at 7s. 6d. per acre, half to be sold in Adelaide, and half in London. A second survey of 250,000 acres was to be made later, and the price per acre was to be raised to 12s. In fact, the ultra-tropical north was to be managed on the most correct South Australian principles. In March 1846 the first land-orders were simultaneously disposed of in Adelaide and London, and all applications not taken up by the general public were bought by companies formed in England and the colony. On 29 April 1864 the government chartered the ship *Henry Ellis*, and appointed Boyle Travers Finniss (q.v.) head of the proposed settlement. The *Henry Ellis* anchored in Adams Bay in June, and Finniss sited his settlement at Escape Cliffs, in spite of the fact that it was 'one of the most inhospitable, unwholesome wastes possible to find. Dysentery, scurvy, fever, and sore eyes became general.' The medical man and the surveying staff in vain pointed out its utter unsuitability; finally the camp broke into open revolt, a party of six seized the only boat and what stores they could and set out for Adelaide, and as a result of their reports Finniss was recalled and retired. The next move of the government was to sell township allotments before survey, each allotment to include a country section of 320 acres, land-orders being given to purchasers upon the understanding that the survey would be completed within a specified date. In December 1868 Surveyor-general G. W. Goyder was sent with a large staff to survey these allotments. Port Darwin was selected as the site of the chief town Darwin—at first named Palmerston—and country selections were surveyed with that as a centre; but, the survey not being completed within the specified time, many holders of land-orders demanded their money back, litigation followed, and the government had to pay in all £73,000. When the survey was at last completed, interest in the Territory had died.

In 1871 the overland telegraph-line (q.v.) was constructed between Port Darwin and Adelaide, and soon afterwards the story reached Adelaide that, while men were sinking holes for the telegraph-posts, gold had been found. Prospecting parties and companies were formed, ships were chartered, and there began 'one of the wildest gold rushes ever made.' The first party (Westcott's) found gold at Yam Creek; then followed finds at Pine Creek, Howley, Bridge Creek, and other places. Innumerable companies were formed, and men, managers, and machinery were sent up to develop the properties.



AUSTRALIA, SHOWING SECTION ON EVERY THIRD DEGREE OF LATITUDE. **(The vertical scale bears no relation to the scale of miles.)**

In most cases the men were engaged for a year, and usually left when their time was up, as tinned food was not to their liking. With this departure of labour the mining industry collapsed, and the one attempt at cultivation—De Lissa's sugar plantation—was on the brink of failure. In 1874 Captain Douglas, the resident at Port Darwin, was commissioned by the South Australian government to engage at Singapore 200 Chinese coolies to save the situation. No intelligence was used in the selection, and most of the imported men were gaolbirds or pirates; but others followed, and by 1880 a comparatively large Chinese population was engaged in mining and the growing of fruit, rice, peanuts and vegetables. A few established a fishing industry. In May 1880 Chinese found gold at the Margaret, on ground that had already been prospected by Europeans, and out of less than an acre many thousand ounces of gold were won.

In 1883 South Australia began to negotiate with the colonial office for a permanent annexation of the Territory; the colony had expended on it £526,137 in excess of revenue received, and was proposing to incur a considerable further expenditure—it was fair, therefore, said the colonial government, that South Australia should have permanent possession of the land. Lord Derby (then colonial secretary) replied that the existing arrangement must stand, but that the Territory would not be made independent of South Australia until in a position to accept responsibility for all moneys spent on it. As it had been alleged that the lack of sound development was due to the costly and inefficient communication between the goldfields and Darwin, South Australia in 1886 made a beginning of a transcontinental railway. At the northern end a line was laid from Darwin to Pine Creek, and a line from Adelaide was gradually extended to Oodnadatta, 700 miles north; this left a gap of 1100 miles, but the colony's finances were drained by developmental works in the south, and at this stage the work had to be abandoned, an attempt to complete the railway by private enterprise on the land-grant system being defeated by strong adverse public feeling.

The coming of federation made it possible to transfer the Northern Territory to the Commonwealth. At first South Australians interested in the potential wealth of central and northern Australia urged the State government to retain the Territory in its own hands and continue the railway northwards at least as far as the Macdonnell Ranges. In 1906, however, negotiations for the transfer were opened, and on 7 December 1907 the transfer was agreed to. A Northern Territory surrender act was passed by the South Australian legislature, and in August 1909 a Commonwealth act—the Northern Territory acceptance act—became law. The Territory was taken over by the Commonwealth as 'The Northern Territory of Australia.' The Commonwealth assumed responsibility for South Australian loans spent on the Territory (a sum of £2,748,062 on 30 June 1909), reimbursing the State the interest paid on those loans, providing a sinking-fund, and paying off the actual deficit; the Commonwealth also agreed to construct a transcontinental railway, purchasing the existing South Australian railway from Port Augusta to Oodnadatta, and completing the line from Oodnadatta to Pine Creek. The total capital thus invested by the Commonwealth in connection with the Territory was:—Public debt on 30 June 1909, £2,748,063; deficit, £779,734; cost of Port Augusta to Oodnadatta railway, £2,242,343; estimated cost of Pine Creek to Oodnadatta line, £4,500,000; total, £10,270,139.

The Territory was formally transferred on 1 January 1911. Immediately radical alterations were made in the administration. Instead of a government resident, an administrator (styled 'His Excellency') and a staff of nine highly-paid officials were appointed. In 1912 a new land policy was framed. At the time of transference there were in existence 265 pastoral leases with a total area of 108,048 square miles —the revenue from them amounted to £6803; there were also 161 pastoral permits, comprising an area of 43,632 square miles and returning annually £2181. The acceptance act had provided that all leases held under South Australian acts should continue on the same terms —an average rental of 14d. per square mile. The new ordinance provided for pastoral leases of 21 and 42 years, rentals being fixed by a board and re-appraised at fixed intervals without taking account of improvements. Leases of agricultural and town lands were to be perpetual; freehold was unobtainable. The first 5000 blocks taken up were to be rent-free for the applicant's lives or for 21 years, whichever period was the longer. Accumulations of leases in single hands were not permitted, and power was taken to resume land for public purposes. Two experimental farms were established, one at Batchelor Farm, near the railway 27 miles from Darwin, the other at Daly River. The completion of the transcontinental railway was not taken in hand for many years, but in 1917 the northern railway was extended from Pine Creek to the Katherine River, and further extensions are now (1926) in progress. Transport from the termini at Oodnadatta and Katherine into the interior of the continent is still performed by camel-train and packhorse, and the cost of carriage is one of the hindrances to settlement. Expenditure has increased out of all proportion to the revenue, and the repeated failure of attempts to carry on tropical agriculture with relatively dear labour has accelerated the financial drift. In 1918 an accumulation of grievances, real and fancied, led to a turbulent gathering outside government house at Darwin which forced the administrator and the judge to quit the country hurriedly. Judge Ewing of Tasmania was appointed a royal commissioner to investigate this riot, and his report of 16 April 1920 was a sweeping indictment of the Commonwealth administration and a condonation of the action of the residents. It also pointed out that whereas under the old regime residents had representatives in the South Australian parliament, they had none in the federal house, and urged that they should be given representation in the Commonwealth parliament. An act of 1923, therefore, allowed the Territory a representative in the house of representatives, who may take part in all debates but has no vote. In the same year a new land ordinance constituted a land board for the Territory, and provided that pastoral leases may be granted for not more than 42 years, the rental being reappraised from time to time; holders of leases under previous ordinances may exchange them for leases under the new ordinance, the rent varying from 2s. to 8s. per square mile. Agricultural lands are classified, and the maximum area for any one lease is: cultivation farms, class i, 1280 acres, class ii, 2560 acres; mixed farming and grazing, class i, 12,800 acres;

class ii, 38,400 acres. Leases are held in perpetuity; the rent for the first period is fixed by the board, and is re-appraised every 21 years. Lessees must stock, fence, cultivate, and build houses as prescribed. Town leases are also in perpetuity; they may be sold by auction or allotted by the board. Lessees must erect within a notified time buildings to the value specified in the conditions of sale. Miscellaneous leases of crown lands may be had for a term not exceeding 21 years. Grazing licences for one year, occupation licences for five years, and miscellaneous licences of one year may be granted by the board. The governor-general may lease to an aboriginal not more than 160 acres of land for any term of years.

Private enterprise has been no more successful than the government in developing the country. In April 1917 extensive meat-works were opened, with plant and buildings costing £900,000. During 14 weeks in that year 19,000 cattle were treated; in 1918 and 1919 operations continued for 16 weeks in each year, the 'kill' in the former year being 29,000, and in the latter 22,000. But labour troubles soon began; demands for higher wages and the introduction of the 'go slow' policy alarmingly diminished the output per unit and so delayed the shipping of the products that it became impossible to induce ships with refrigerators to call. In the end the company was compelled to close down; the works are still idle, and the pastoral industry is at a standstill. As the net result of over 15 years of Commonwealth control, the expenditure of much money, and many attempts to start industries, the Northern Territory is to-day carrying fewer white people, and is less prosperous, than it was half a century ago. In its uninhabited and undeveloped condition it represents an open doorway to Australia.

The total area of the Territory is 523,620 square miles, its length from north to south about 900 miles, and its breadth from east to west 560 miles. All its land boundaries are artificial lines. The eastern boundary reaches the coast near the mouth of the Wentworth River in the Gulf of Carpentaria, the western at Cape Domett, near Cambridge Gulf. The coast-line is about 1040 miles long, giving 503 square miles of area to one mile of coast-line. It is intersected by a number of rivers, many of which —including the Roper, the Adelaide, the Daly,

and the Victoria—are navigable for from 20 to 100 miles. Of the many valuable harbours Port Darwin is equal to any other in Australia. The town of Darwin is laid out with wide and level streets; the buildings, for the most part government offices, are of stone. At Darwin are a cable station and the terminus of the overland telegraph. Agriculture was attempted in 1824, 1827, and 1838, but no extensive operations were begun until the settlement was made at Port Darwin in 1869. In 1871 a few plantations were attempted, but failed owing to the inexperience and extravagance of the planters. In 1879 about 550 Chinese arrived, and fruit and vegetables were soon produced in abundance. In 1884, however, the Resident reported that the condition of agriculture was very disappointing. Subsequently a botanic garden was established in which sisal hemp was grown successfully; it 'nearly overran the garden.' An act of 1890 provided for agricultural leases with the right of purchase, and a number of areas were taken up, but the lessees failed to cultivate their holdings properly. In 1907 provision was made for the taking up of land for mixed farming, and in 1911 experimental farms were established. It has been proved that, given sufficient labour and efficient transport, rice, tobacco, cocoanuts, mangoes, cotton, various fodder-plants, and peanuts can be grown easily (see PEANUTS and RICE).

In 1886 stock was brought to the Macdonnell Ranges from South Australia; six years later cattle were brought from Queensland to the northern areas, and in 1879 2000 head of cattle and 12,000 sheep from South Australia were depastured at the Katherine River. Sheep-raising, however, failed for lack of water. The cattle industry progressed slowly; on 30 June 1925 there were about 855,000 cattle in the Territory, but the closing down of the meat-works in April 1920 had by that time seriously affected the industry, which has also been impeded by ticks and by the difficulty of 'travelling' stock. However, dipping is diminishing the tick-pest, and the sinking of more artesian wells on the stock-routes, and the creation of stock-reserves, is easing the difficulty. Horses thrive well—in 1925 they numbered about 46,000—and 1538 buffalo-hides were exported in 1924-5.

The Territory is rich in minerals, including gold, tin, wolfram, silver-lead, copper, and mica. The presence of coal and of mineral oil is suspected, and on 31 December 1925 licences to search for these minerals, covering an area of 5,256,246 square miles, were current; actual

prospecting, however, has been so far confined to bores put down on Elcho Island. In 1884 pearl-shell was discovered in Port Darwin; the progress of the industry was hampered, at first by local difficulties, afterwards by the outbreak of war in 1914, but during 1924 14 tons of shell was exported to the United Kingdom. The Territory's waters teem with marketable fish, and, despite inadequate transport facilities, a beginning has been made with the export of fish, dried or otherwise preserved; in 1924-5 exports to the value of £1831 went to British Malaya and China.

There is a monthly postal service between the Territory and the eastern States, and State-owned Western Australian vessels give a 60-day service between Fremantle and Darwin. The northern interior receives its mail via Darwin, the southern districts are served from Adelaide via Oodnadatta. The overland telegraph-line is separately described. High-powered wireless stations have been constructed by the Commonwealth at Wave Hill in the Territory and at Camooweal just over the Queensland border. Railway communication is being completed along the Adelaide-Darwin route; but this line serves only a strip of the Territory, and it is proposed to construct another line south-east from Katherine River towards Camooweal in Queensland, with a branch running down the McArthur River to a new port in the Sir Edward Pellew group which will have far better climatic conditions than Port Darwin. This line will open up excellent grazing areas of the Barkly tableland, and give much of the Territory quicker communication with the well-populated areas of the eastern coast.

The total cost of the Northern Territory to the Commonwealth up to 30 June 1926, including the estimate for 1925-6, was £8,766,337. This sum is made up of the indebtedness taken over at the transfer from South Australia, £3,931,086; accumulated deficit, £3,401,182; new works (buildings, roads, bridges, bores, etc.), £472,912; and construction of and capital expenditure on railways, £961,157. J.V.C.-B.

Notelaea, a genus of the family Oleaceae, consisting of seven species of trees or shrubs known as 'mock olives,' endemic in Australia and mostly confined to the eastern States. The flowers are small, the petals connected in pairs by the stamens; leaves opposite and entire; fruit succulent. *N. ligustrina,* a small tree with varicoloured fruits, is the Ironwood of Tasmania. It has a hard, close-grained wood, considered to be a fair substitute for *lignum-vitae. N. longifolia* is the 'coobagum' of the aborigines. It has a very hard timber, and hence is known to bushmen as 'axe-breaker.'

Nothofagus, a genus of trees (rarely shrubs) of the family Cupuliferae. Three species are indigenous. *N. Cunninghami* (Myrtle Beech), a tree usually of 40-50 feet, but occasionally in rich damp valley soil reaching 200 feet, occurs in Victoria and Tasmania; its timber is much used by carpenters, and is very suitable for saddle-trees. *N. Moorei* (Red Beech, Negro-head) is a very beautiful evergreen shade-tree with durable timber. Its habitat is the coastal range of New South Wales in its upper valleys from the Hunter northwards; it attains to 150 ft., with a stretch of 70 feet before the first branch is thrown out. In foliage it resembles *N. Dombeyi,* a Chilean beech, rather than its fellow-

Negro-head.

Australian species. *N. Gunni,* a Tasmanian species, is a deciduous shrub rarely more than 8 feet high.

Nototherium. See PALAEONTOLOGY.

Notothixos, a small genus of the family Loranthaceae; all the species are endemic in eastern Australia. The flowers are minute, unisexual, in small heads on a common stalk; calyx produced into a narrow border. *N. subaureus* is divaricately branched, and the young shoots and under-side of the leaves are clothed with golden hairs. It is a common parasite on the swamp she-oak, and frequently occurs on other parasitic loranths.

Noxious Animals. This article is concerned only with mammals. In Australia the term 'noxious animals' is much misused and misunderstood. The mammals in Australia which may be classed as distinctly noxious are extremely few, but according to various State laws almost any species may be declared noxious within the meaning of some particular act. A typical case is that afforded by section 67 of the Pastures Protection Act of New South Wales, wherein power is given to the authorities to declare any animal in any district noxious, if it is 'found to be detrimental to the stock or pastures thereof.' Or, again, a species may be placed upon a list of 'unprotected' animals, in accordance with powers given under a birds' and animals' protection act, or a game act; it then automatically (though often wrongly) comes to be looked upon as noxious.

The outstanding noxious animals of Australia are the European rabbit, the European hare, the native wild dog, or dingo (*Canis dingo*), domestic dogs which have gone wild, hybrid dogs of many types (produced by the crossing of domestic dogs and dingoes), the European fox (*Canis vulpes*), the domestic cat in a wild state, and the flying foxes or fruit-eating bats (see BATS). Certain marsupials also are regarded as pests at various times and in various places. To the native animals already mentioned may be added the dasyures (such as the tiger cat and the native cat), the wombat, the bandicoots, and certain kangaroos and wallabies (including the paddymelon and the kangaroo-rat). The number of these native animals has, however, so far diminished that they have almost ceased to be pests, except, perhaps, in districts where they have been rigidly protected for a long time.

The *Rabbit,* the worst pest of all, is dealt with in a separate article.

The *Hare*, though frequently amounting to a pest in various places, has never at any time or in any part exercised the same mischief as the rabbit. This is chiefly due to three causes: (1) that it is less prolific than the rabbit, (2) its relative lack of adaptability to greatly varying conditions of rainfall, climate, and food-plants, and (3) its non-burrowing habit. Probably the non-burrowing habit has more to do with its comparative harmlessness than anything else, since it has always been a tolerably easy matter for gunners and packs of dogs to kill it off. Nevertheless the aggregate destruction of pasturage and food-crops wrought by this rodent has been very great, more especially in the eastern coastal districts. The opening up of the North Coast farming areas of New South Wales gave a great fillip to the increase of the hare, but with the rapid spread of population in this quarter there is no danger of the pest getting beyond control.

The *Dingo*.—Though the dingo (q.v.) is found throughout a very large part of Australia, in many parts of the open country it is rare or almost absent. Its great stronghold is in districts containing more or less rugged, hilly, or mountainous country, or contiguous to heavy timber; but numbers are to be found in desert and semi-desert country also. Until recent times they were so bad in the far north-west of New South Wales that they prohibited sheep-breeding over a large section of the country, taking all the lambs as well as many of the grown sheep. At the present time, however, they are to a considerable extent under control in this area, and many sheep are being bred. Taking Australia as a whole, it is probable that there are fewer dingoes now than formerly; but the loss of sheep and lambs through their depredations is still very great. Whereas great stretches of country which once harboured them are now free, there are others in which they were once scarce, but now flourish. This has been brought about by the rabbit, upon which the dingo will feed if opportunity offers. Their onslaught on sheep and lambs has been caused, to a considerable extent, by the great diminution of native wild life which has taken place in the last 30 years. The dingo certainly acts as one of the principal obstructions to rabbits in their attempts to pass through stretches of range or forest country.

In most districts in which dingoes abound, a bonus is paid for their scalps by local authorities or by government. These bonuses may range from about 7s. 6d. per head for pups to £1 for the full-grown dog, but in some cases the same bonus is paid for both. Occasionally as much as £10 is paid by station-owners for the destruction of a dingo whose depredations are extensive, and a local 'bad killer' has brought as high a sum as £50.

Domestic Dog 'gone wild' and Dingo-Dog Hybrids. In addition to the original pure-bred dingo, there are many other wild dogs throughout the Commonwealth. Some of these are town, farm, and station (frequently rabbiters') dogs which have run wild, but in most instances they are hybrids of the dingo and various types of domestic dog. Most of the worst sheep-killers are crosses between dingoes and sheep- or cattle-dogs. There are no recent reliable figures showing the destruction of stock by dingoes and other dogs, but it is recorded in New South Wales official reports that during the 10 years from 1884 to 1893 (inclusive) 566,238 sheep were destroyed by 'tame' dogs, and 802,369 by wild dogs (dingoes and crosses). In Queensland the latest annual figures available (1925) show a loss of 221,000 sheep attributable to the dingo. These dogs, therefore, form a grave menace to the pastoral industry.

The *Fox* has spread over a large part of Australia—having, broadly speaking, followed the rabbit, but, not being quite so adaptable, it has so far failed to penetrate into the highly arid places, in which the rabbit is able to maintain itself in security if not in comfort. The fox undoubtedly exercises a certain restraint upon the rabbit, but for all that it may be looked upon as one of the worst of the noxious animals. Not only does it destroy great numbers of birds—especially ground-birds—but in every State it accounts annually for many lambs and even full-grown sheep. During the three years ending with 1915, some 207,000 sheep (including lambs) were recorded as having been destroyed by foxes in New South Wales alone. In cattle-raising parts but little attention is paid to their existence.

The extent to which the destruction wrought by the fox has retarded poultry-farming is very great. At the time when he first made his appearance on the upland plains of Monaro in New South Wales, turkey-raising was being conducted on a large scale and very economically—the birds simply roaming the open country. The fox quickly altered that. Everywhere in the poultry-raising industry the precautions continually taken against him have added greatly to the cost of production.

The earliest Australian record of foxes comes from Victoria. Between 1870 and 1880 (according to the *Ballarat Star*) Dr. King imported a pair for breeding. There were many other introductions at various times. In Western Australia, where they are not numerous, the first fox was recorded in 1915. Tasmania alone of the States has prohibited its introduction. No complete record of the destruction of foxes is available for the Commonwealth, and though 48,077 are recorded as having been destroyed in New South Wales during the five years 1920-4, this is undoubtedly but a small percentage of those killed in that State. A price is set upon the fox's scalp, ranging in various places from as low as 2s. 6d. up to £1. The fox shows a variation in fur and physique similar to that which is displayed by the rabbit. In the uplands it is larger and has a much heavier coat than in the drier and warmer lowlands.

The *Domestic Cat*.—For many years the common cat has been living in a wild or semi-wild state in many parts of Australia. While to some extent subsisting upon rabbits, it is primarily a destroyer of bird life, and much destruction of native birds (especially of tree-living insectivorous species) is due to it. In its wild state the domestic cat becomes a fine animal with a strong, glossy, heavy fur; some are exceedingly large. The skins are in good demand in the fur-market, and this to some extent reduces the pest; many thousands of the skins pass annually through Australian dealers' hands. Not infrequently cats are to be found living in the rabbit-warrens.

Flying Foxes.—At least two species of fruit-eating bat—familiarly known as flying foxes (see BATS)—are a very serious menace to fruitgrowers. Both the larger species (*Pteropus poliocephalus*) and the smaller (*Syconycteris australis*) do great damage to the soft crops—such as peaches, apricots, plums, nectarines, pears, figs, etc. Not only do they actually con-

sume the fruit, but a vast amount of ripe fruit is damaged and knocked off by them. Other fruits, e.g. apples and quinces, also suffer. At times these bats move over the land in immense flocks, wreaking great havoc. In the day-time they repair, if possible, to some dense thicket or scrub, where large umbrageous trees are to be found, and there they hang in thousands. On several occasions settlers have shot many thousands at one rookery.

The *Native Cat* (q.v.) and the *Tiger Cat* were at one time extremely numerous, and destroyed much poultry. But the last 20 years have seen a great diminution in their numbers, and in many districts they have ceased to exist. Even when at their worst as poultry-destroyers these dasyures exercised a very considerable restraint upon the spread of the rabbit in the eastern and central districts of New South Wales.

The *Wombat* (q.v.) makes its home chiefly in wooded and mountainous country. In certain parts the farmer regards this marsupial as a pest because of its habit of tearing through, or uprooting, the wire-netting fences, and so allowing the entry of rabbits.

The *Bandicoot* (q.v.) is frequently looked upon as a noxious animal because of its tendency to burrow in gardens in order to get at the roots of certain plants, including tubers of various sorts. Yet even at their worst these little animals have nowhere done a fraction of the damage wrought by even a few rabbits, and, where rabbit-proof netting is well maintained, the damage caused by bandicoots is infinitesimal. The burrows made by either the long-nosed or short-nosed varieties are only slight excavations. The bilbee, or rabbit bandicoot, is a nocturnal animal, and so not often seen. Though it has completely disappeared from a large part of its original habitat it is still to be found in western Queensland.

Kangaroos and *Wallabies* (q.v.).—Opinion varies greatly among pastoralists as to the amount of damage done by these marsupials. When pasturage and water are scarce, and starving kangaroos are crowding in, they undoubtedly become a pest to the sheep-owner; but under normal circumstances they can hardly be considered noxious. Wallabies, however, are regarded as a pest in Queensland, particularly in the coastal areas, where farmers in many places are compelled to protect the crops with wire-netting fences. Netting for this purpose is supplied by government on long terms of repayment.

The *Wild Pig*.—In parts of Queensland and New South Wales the domesticated pig, gone wild, causes some destruction to crops and to rabbit-proof wire-netting fences. These pigs are mostly to be found in the vicinity of marshes and lakes, and in country intersected by billabongs and other river backwaters. D.G.S.

Noxious Birds. Of all imported birds the Starling (*Sturnus vulgaris*) is the most noxious. Indigenous in Europe and Asia, probably not a native of the British Isles, where it has been noted as a fruit-pest—especially in the cherry orchards of Kent—it has spread throughout a great part of Australia. A voracious feeder and prolific breeder, the starling takes toll of fruit-growers, farmers, and market-gardeners, its food consisting chiefly of cultivated fruits and cereals. It is sometimes advanced in the starling's favour that it rids sheep of ticks and destroys large numbers of insects; but birds taken from among flocks of sheep have been closely examined, and no sign of ticks has been found in their stomachs. On the other hand the stomach-contents of starlings investigated over a period of 12 months show 70 per cent of vegetable and 30 per cent of animal matter, and of the vegetable matter cereals often amounted to 20 per cent. Undoubtedly starlings help other birds to keep down grasshoppers; but this benefit is altogether outbalanced by their continual depredations.

Starlings, moreover, being strong and aggressive, attack the useful insectivorous birds native to Australia, and drive others—including swallows—from their nesting-places, passing on the parasitic vermin with which starlings themselves are notoriously infected; in the native birds these parasites produce skin diseases which cause all their feathers to drop off. The starling is also a great distributor of noxious seeds, notably of the African box-thorn, besides being a nuisance to people whose houses it selects for its nests and proceeds to fill with vermin.

The date of the first introduction of the starling into Australia is uncertain. In 1863 the ship *Princess Royal* landed in Melbourne starlings, sparrows, and three hives of Ligurian bees, and in that year starlings were sold in Australia in the open market. During the first few years after their introduction they kept closely to the seaboard, roosting in the mangroves. In recent years they have been traced as far north as Lake Callabonna in South Australia, to Ooldea on the trans-Australian (east-west) railway, and to Rockhampton in central Queensland. A few years ago a pair started to nest in the Albany district of Western Australia, but were fortunately destroyed before hatching their brood.

Second only to the starling among imported pests is the House Sparrow (*Passer domesticus*), which was introduced into New South Wales in the early days. The *South Australian Advertiser* of 22 July 1863 mentions a sale of birds brought out in the ship *Orient*, at which an English cock-sparrow—the sole survivor of 100 that had been shipped—was sold for 11s., while two blackbirds brought 68s. In 1865 another consignment was brought by the same ship and handed over to the botanic gardens. Sparrows are responsible for damage to cereals, fruit, and other produce to the value of hundreds of thousands of pounds annually throughout the eastern States, but have not yet become established in Western Australia. They are, however, extending along the east-west railway as far as Ooldea on the edge of the Nullarbor plain, and as far as Eucla on the coast. Their method of advance has been closely observed. One or two will appear at a dwelling for a few days only, and then disappear; very shortly, from six to a dozen will put in an appearance, and at once establish themselves, subsequently sending scouts farther out. Oodnadatta (the dead-end of the Northern railway of South Australia) they have reached in vans that conveyed corn, having been seen to fly from the vans when opened. They have also been traced along the line of cattle-stations from the railway to Lake Frome.

Sparrows destroy a great deal of insect-life, especially when feeding their nestlings (that is, several times a year), but this benefit is greatly outweighed by the damage done to cereals and fruit-crops. Their depredations, however, rarely occur far from human habitations. In farming

areas the investigation of their stomach-contents shows that for several months every year 70 per cent of a sparrow's food consists of cereals. In towns they give additional trouble by choking gutters, spouting, etc., with the grass or straw of which they build their nests. The sparrow is a gregarious bird and forms large flocks during the winter, when it can most effectively be dealt with.

The English Blackbird (*Turdus merula*) has of late years become established in certain districts of Victoria, Tasmania, and South Australia, but little is known of it in the other States. Fortunately its habit of keeping to the thicker undergrowth in damp gullies or well-timbered slopes of the ranges has so far restricted its advance over open country. Its partiality for berries and soft fruits, and its habit of scratching over damp soil, make it an enemy of the gardener, whose seed-beds it destroys. In Europe snails form an important part of its diet, but in Australia it despises them; moreover, it will not touch even berries and seeds until it has devoured all the soft fruits within reach.

The Goldfinch (*Carduelis carduelis*) plays havoc among berry fruits—raspberry, strawberry, etc. It undoubtedly destroys the seeds of many noxious weeds—mostly thistles—but it also takes large toll of other plants, so that the market-gardener incurs great expense in protecting his seed. The goldfinch is increasing rapidly, and has been traced far from the more populous districts. It congregates in large flocks in January; in August or September the flocks break up, and distribute themselves over the country to begin nesting. They like fruit-trees for this purpose, and use the flowers of apples and pears for building-material. They also pull to pieces many varieties of flowers in order to get at the soft seed at the base of the petals. They have been seen to attack the native robins and flycatchers, and drive them away from nesting-sites which they had used for years.

The English Greenfinch (*Chloris chloris*) is one of the latest of foolish introductions. A larger and stronger bird than the sparrow, with a stronger bill, it is increasing rapidly, and must, unless checked, become a source of loss to farmers and fruit-growers. It has already begun to attack standing grain-crops and seeding plants; it is also eating soft vegetables (such as lettuce, cauliflower, and cabbage) in the seedling stage. It does good, no doubt, by destroying Scotch and other thistle seeds.

Since so far no preventive legislation has been enacted by State or Commonwealth governments, foreign birds are allowed to enter Australia almost without control. Until such legislation is effected, other bird-pests may at any time be introduced.

S.A.W.

The Red-whiskered Bulbul (*Otocompsa emeria*) appears to have been introduced at Sydney about 1905; possibly a pair escaped from an aviary or were given their freedom by thoughtless owners. Rather larger than a house sparrow, the bulbul is brownish above, gray and white below, and blackish about the head; more distinguishing features are a sharp, black crest and a patch of crimson beneath the tail. It has a cheerful voice, and does some destruction among insects. On the other hand, evidence collected on behalf of the Australian Museum at Sydney shows definitely that the bird has a strong liking for soft fruits, particularly figs, grapes, apricots, peaches, and mulberries; in a single orchard bulbuls have been known to strip 30 bunches of grapes, and eat large holes in about 100 apricots, 100 nectarines, and 200 peaches. Probably it is the only bird that attacks tomatoes; it is fond also of the berries of the camphor laurel and pepper trees, tips of green pea-plants, and petals of various flowers. An examination of the stomach-contents of several birds failed to disclose insects, the food having been fruits, greens, or berries. As the bulbul is at present confined to Sydney and suburbs, a studied offensive would probably stamp it out. It has been officially declared a pest.

The Indian Dove (*Streptopelia chinensis*), common in Melbourne, Sydney, and Brisbane, and now pushing out into the country districts, is an unmitigated nuisance as a seed-eater and as a usurper of the rights of native birds.

A.H.C.

Noxious Insects. See BEETLES, BITING-LICE, BLOOD-SUCKING FLIES, BOT-FLIES, CATTLE-TICK, CICADAS, COCCIDAE, CRICKETS, EARWIGS, FLEAS, FLIES, GRASSHOPPERS, HEMIPTERA, HYMENOPTERA, MOSQUITOES, MOTHS, SHEEP-TICK, STICK-INSECTS, THRIPS, THYSANURA, WHITE ANTS, WOOD-BORERS.

Noxious Plants. The majority of plant-pests are of alien origin, and few of these are pests in their original habitat: they have become noxious in Australia because (*a*) the new conditions altered their habits and encouraged an abnormal growth, (*b*) their introduction was not counterbalanced by that of their natural enemies. Of these causes the second is the more important. The prickly pear (q.v.), the lantana, the sweetbrier, which in their native environment are comparatively innocuous, are in Australia a menace to agriculture partly because its soil and climate suit them, but mainly because they are not infested with the fungi or mites or larvae that elsewhere checked their undue extension, nor eaten down by the animals that frequented their country of origin, nor destroyed at an early stage as they would be in more densely populated areas.

The most dangerous pest, the prickly pear, is dealt with in a separate article. In the coastal districts scarcely less noxious is the Water Hyacinth (*Eichhornia crassipes* or *speciosa*), an aquatic plant introduced from South America and sometimes cultivated in parks and gardens for the sake of its beautiful racemes of mauve flowers. About the year 1900 a fragment was innocently liberated in Swan Creek, a tributary of the Clarence River in New South Wales, and in two years the hyacinth was in possession of the full 50 yards' width of the creek. Flower-lovers carried it thence to their own homes, and soon the rivers of northern New South Wales (and later on those of Queensland) were infested by the pest. In January 1911 the hyacinth caused a suspension of the traffic at Grafton, and several punt-wires were broken on other parts of the river. Every flood brought down acres of the plant. Many thousands of pounds have been spent to clear navigable channels, but it is difficult to eradicate the weed in sluggish water. Cattle readily eat it, and are often—especially in times of drought—drowned through slipping into deep water and becoming entangled in the root-growth. The foliage is killed by frosts in winter, and the plant will not grow in salt water.

Lantana camara, a member of the verbena

family, introduced as an ornamental shrub from tropical America, has overrun large areas of eastern Australia, chiefly through the agency of birds. It smothers the native plants and renders their habitat difficult of access, but is easily destroyed, and is said actually to improve the soil in which it has grown—e.g. along the Queensland rivers. Sweetbrier (*Rosa rubiginosa*), said to have been first introduced from Scotland, has ruined large areas of grazing-land throughout the cooler districts of all the States. It is spread both by seed and by sucker. Blackberry (*Rubus fruticosus*) has become a pest among the highlands and gullies of the southern half of the continent. In the Illawarra district of New South Wales, throughout Gippsland and other parts of Victoria, on Mount Lofty in South Australia, and in the mountain regions of Tasmania, the blackberry dominates and kills off the indigenous flora; but in some of these districts there is a slight compensation in the tons of fruit picked for jam.

Most of the following thistles were introduced with fodder from Europe:—the Star Thistle (*Centaurea calcitrapa*); Cockspur (*C. melitensis*); Black or Spear Thistle (*Carduus lanceolatus*); Canadian Thistle (*C. arvensis*), very prevalent in Tasmania—its creeping roots are difficult to eradicate; Saffron Thistle (*Carthamus lanatus*); Scotch Thistle (*Onopordon acanthium*); Blue Thistle or Viper's Bugloss (*Echium vulgare*), best known as 'Paterson's Curse,'—Maiden calls this *E. plantagineum*; Russian Thistle (*Salsola kali-tragus*); Prickly or Mexican Poppy (*Argemone mexicana*).

Burrs are particularly obnoxious to pastoralists, as they depreciate the value of wool. On the other hand, wool and sheep are responsible for the wide distribution of weeds. Thus in 1913 there were exhibited before the Linnean Society of London 46 Australian plants found growing in England near wool-washing establishments, together with a large collection of Australian seeds obtained from Australian wool. Far the worst of the imported burrs is the Bathurst Burr (*Xanthium spinosum*), said to have been brought in the tails of horses from Valparaiso about 1840. It is a native of Chile, but derives its Australian name from the fact that Bathurst was the first district in which it was noticed. It is now widely spread over all the States. Its taller-growing ally, the Noogoora Burr (*X. strumarium*), a native of Europe, known in the United States as the clot or cockle burr, is found chiefly in Queensland and northern New South Wales, where whole paddocks are rendered useless by it. The Buffalo Burr (*Solanum rostratum*) from North America is thoroughly naturalized. The Apple of Sodom (*S. sodomeum*), a native of Africa, is noxious as being not only prickly but highly poisonous; the fruits contain an alkaloid, and have been known to be fatal to children. Hedgehog or burr-grasses are everywhere troublesome to stock; *Cenchrus australis* has a sticky seed which mats the hairs of animals and has been recorded as catching insects. Other well-known imported burrs are the Chinese Burr (*Triumfetta rhomboidea*), the Sheep's Burnets (*Acaena ovina* and *A. sanguisorbae*), and the Medic Burrs (*Medicago denticulata* and *M. truncatula*); the last-named, while injurious to wool, are excellent fodder. The Bindi-eye or Bogan Flea (*Calotis cuneifolia*), a native of Australia, is both injurious to wool and a source of irritation to man and beast.

The following weeds have specially noxious characters. Nut-grass (*Cyperus rotundus*)—a cosmopolitan pest, wild in North America—is perhaps the worst garden-weed in Australia. It was probably introduced with pot-plants, and is well known in city parks and botanic gardens. Careful sifting of the soil of infested beds seems to be the sole remedy, except that of allowing pigs a free run. St. John's Wort (*Hypericum perforatum*) is dealt with under its own name. The Cape Weed (*Cryptostemma calendulaceum*), now almost ubiquitous in Australia, is quoted by Maiden as forming 'hair balls' in the intestines of cows when the seed is licked, as do the spinules of the prickly pear and the awns of the Wild Oat (*Avena fatua*). Cape weed should not be confused with Cape Tulip (*Homeria collina*), a much more poisonous African weed which is causing grave concern in Victoria; in New South Wales it has been located in one shire only.

The Castor-oil Plant (*Ricinus communis*), probably a native of Africa, is found on wastelands in coastal regions; its poisonous seed is a standing menace to children as well as to stock. Another proclaimed weed, *Jatropha gossypifolia*, is often called 'castor-oil plant' in Queensland. The Thorn Apple (*Datura stramonium*) is often confused with the castor-oil plant, and bears a seed which has also been recorded as poisoning stock. The Wild Tobacco (*Nicotiana glauca*), from the Argentine, has been found curiously fatal to ostriches, and more rarely to cattle; this plant must not be confused with *Humea elegans*, an indigenous scented 'feather plant' which is a skin irritant, also (but erroneously) called 'wild tobacco.' The Stinkwort (*Inula graveolens*) of southern Europe first appeared as a pasture-pest in South Australia about 1850. It is now proclaimed a pest in all the States, as is the Purple Top (*Verbena bonariensis*) from South America. Other unwelcome Americans are the Red Ink Plant (*Phytolacca octandra*), especially troublesome in tropical and subtropical areas, and Stinking Roger (*Tagetes glandulifera*), which promptly takes possession of cultivated land in Queensland and New South Wales, grows eight feet high, and 'can be smelt half a mile off.' The cosmopolitan Sorrel and Dock (*Rumex acetosella* and *R. crispus*) are especially contumacious in the cooler districts of southern Australia and Tasmania.

Australia has very few poisonous plants, but the death of stock from no obvious cause is often attributed by stockowners and their employees to poison in the fodder. Investigations into this matter are still (1926) in progress, but the following provisional conclusions may be stated here:—

(1) Certain plants contain a glucoside which, when acted upon by a ferment in the plant, liberates hydrocyanic (prussic) acid; these plants are highly poisonous, some throughout the year, some at certain seasons or stages of growth. Among them are Blue Couch-grass (*Cynodon incompletus*), Variegated Thistle (*Carduus marianus*), Johnson Grass (*Sorghum* or *Andropogon halepense*), and various species of oleander (*Nerium*). For Johnson grass see GRASSES and SORGHUM AND MILLET.

(2) A few plants contain saponin (another form of glucoside) and even more virulent poisons; among these are certain Leguminosae (*Gastrolobium, Oxylobium, Isotropis*), especially their Western Australian species, and at least two Solanaceae—*Duboisia Hopwoodi*, the pituri of the aborigines (see DUBOISIA), and *Anthocercis littorea*, which is said to have poisoned children in Western Australia.

(3) The Milk-weed (*Euphorbia Drummondi*) and the Stagger-weed (*Stachys arvensis*) are reputedly poisonous; but enquiry shows that only tired and hungry animals which eat them im-

moderately are affected, the cause of death being indigestion followed by flatulency.

(4) Certain Leguminosae—e.g. *Swainsona*, of which genus the Darling pea (q.v.) is a species—derange the nervous system of stock, the symptoms being analogous to those usually associated with lathyrism and loco disease. Animals may develop an inordinate appetite for the plant, and become inveterate 'pea-eaters;' this renders them useless for the short remainder of their lives.

Legislation, etc.—The underlying principles of the various Australian acts dealing with noxious weeds are (*a*) that the Commonwealth should prevent their introduction from other countries, (*b*) that the States should control the spread of known weeds within their own borders and educate agriculturists in recognizing and destroying them, (*c*) that local authorities should have power, subject to a State veto, to proclaim particular plants 'noxious' within their own areas and should be the direct authority controlling eradication. The defect in this system is that crown lands—which cannot be controlled by the local authorities—are often the breeding-grounds of noxious plants, and become prolific centres of infection in agricultural districts. The Commonwealth's share of the work is effected by the administration of the quarantine acts, 1908-15, under which over 100 genera may not be imported. Each State has its own rules, which unfortunately are not always concordant in neighbouring States; thus blindweed, nut-grass, and several thistles are proclaimed in Victoria, but grow unchecked in New South Wales. Moreover within a single State many plants may be reckoned 'noxious' in one area and harmless just beyond an imaginary boundary-line. Thus, whereas 200 municipalities and shires have proclaimed the Bathurst burr, and over 100 the blackberry, only 11 have proclaimed the Scotch thistle. This variance is, of course, due partly (but only partly) to the fact that the weeds occur only in certain areas and are not proclaimed where they do not occur.

The native weeds are at present few in number, species, and individuals, but they tend to increase as the edible species in their area are eaten out; thus additions are constantly made both to the list of noxious plants and to the areas in which proclamations run.

Nut-grass. See NOXIOUS PLANTS.

Nuthatch. See TREE-RUNNERS.

Nuts, a name applied promiscuously to many shrubs and trees whose fruit is known vernacularly as a nut. The marsh nut is a *Semecarpus*; the nicker nut a *Caesalpinia*; the union nut one of the Rutaceae.

Nuytsia, a genus of the family Loranthaceae, whose single species, *N. floribunda*, is endemic in Western Australia, occurring in the coastal region from Albany to the Murchison. It attains a height of 35 feet and a diameter of 2 feet; flowers with 6 narrow petals—the supporting bracts enlarge after the flowers fall; leaves narrow, 1½-3 inches long; fruit a dry nut,

Nuytsia (*Loranthus*) *floribunda.*

with 3 short thick wings. It is root-parasitic on certain banksias, and consequently difficult to transplant. The seeds germinate freely, but do not as a rule reach maturity. The wood is soft and spongy, and the tree is but too readily the victim of advancing settlement. It is popularly known as 'mistletoe-tree' or 'Christmas-bush,' and sometimes as 'Swan River blaze-tree;' its masses of brilliant orange-coloured flowers (which, as with the flame-tree—*Brachychiton*—of eastern Australia, occur in great profusion while the tree is still bare of leaves) appear about December and make it one of the most gorgeous flowering trees in the world. See CHRISTMAS BUSH.

Nuyt's Land. See AUSTRALIA, DISCOVERY OF.

O

Oak, a name applied usually to species of the family Casuarinaceae (q.v.), the grain of the timber resembling that of the English oak. But the silky oak (q.v.) is a *Grevillea* and the red silky oak a *Stenocarpus*.

Oakes, Rebecca (1788-1883), born at Sydney on 22 September 1788, was the first white girl (and the second white child) born in Australia. She was the daughter of John Small, who is usually described as a 'private in the New South Wales Corps whom Phillip made sergeant of his bodyguard;' but as Phillip is not known to have had a special bodyguard, and the Corps did not reach Sydney till June 1790, 21 months after Rebecca was born, this description is obviously inaccurate. In 1807 Rebecca married Francis Oakes, who had been a lay member of the London Missionary Society's party that sailed for Tahiti in 1796, were forced to abandon the mission in 1798, and settled in New South Wales, where they were welcomed by Hunter and described by Marsden as 'resolved to settle, and to accelerate the improvement of the Colonial manners by public instruction and domestic example, by manual industry, and by their labours in the service of virtue.' Oakes obtained a grant of 100 acres near Dundas in April 1799; in 1805 King made him head constable 'at Parramatta and for the interior,' and in 1806 described him as 'a most useful officer.' In Bligh's time he came into undesired prominence, first as a witness against D'Arcy Wentworth at a court martial, then as the constable who was ordered to arrest John Macarthur (q.v.); Johnston therefore removed him from office, and Bligh in 1810 took him to England as a witness in Johnston's trial. Macquarie had on 10 January 1810 reinstated him at Parramatta, and after long delays in England he returned to New South Wales and resumed duty. The Oakes family was prolific—twelve children, ten of whom themselves had large families. Rebecca Oakes died at Parramatta on 30 January 1883.—One son, Francis, was in 1860-1 a member of the legislative council. Another, George, represented Parramatta in the earlier council in 1848-56, and in the legislative assembly in 1856-60, and sat for East Sydney in 1872-4; in 1879-81 he was a member of the nominee legislative council. He died on 10 August 1881, the first victim of the Sydney steam trams.

Oats are grown more extensively in Victoria than in all the other states put together, although they succeed equally well in special districts in those states. Notwithstanding the extensive area put under oats annually, Thomas Cherry, a former Victorian director of agriculture, considered that the oat crop 'should be made to fill a much more important sphere in farming operations in all parts of the closer settlement country than it does at present. Owing to the way in which the different varieties are adapted to our climatic conditions, the oat alone may be used to supply the farm with green and dry fodders reaching maturity in each of the months from July to January in succession . . . The main crop in all parts of Victoria is the Algerian Oat . . . The rotation to which the practice of most wheat-farmers is approximating is wheat, oats, grazing, fallow; this is not very far from an ideal rotation, having regard to the present position of agriculture in Victoria.'

In New South Wales oats have been grown from the earliest days. The varieties first grown were the Spanish and a very coarse kind; both succeeded in the metropolitan district, where several thousand acres are still grown annually for hay and green feed; but oats are cultivated most extensively on the tablelands and western slopes—in the western plains little is grown, and in the Riverina divisions they grow chiefly for hay. Since 1910 the cultivation of oats has increased considerably in South Australia and Western Australia. In Tasmania the area under crop has been constant.

The three species of oats grown in Australia are: the common or tree-type (*Avena sativa*), the Algerian type (*A. sterilis*), and the Tartarian type (*A. orientalis*). Typical varieties of the tree-type are Sunrise (a good general-purpose, rust-resisting oat), Abundance, Potato, Lachlan, Guyra, and Ruakura (imported from New Zealand). The Algerian variety is perhaps the most widely grown oat, and belongs to the *A. sterilis* group, other kinds being Mortgage Lifter (almost identical with Algerian), Calcutta, and Red Rust-proof; of the Tartarian (or side-oat) group, White Tartarian is the best.

Oats are valuable not only for grain and hay (or green feed), but as a rotation crop with wheat to assist in the control of 'take-all' and smut. Where the wheat-crop is affected with these diseases, the following is a good rotation: —wheat (affected), fallow, oats (for hay or grain), fallow or fodder-crop (rape or oats), wheat (clean).

The area under oats and the yield for the season 1924-5 were as follows:—

State.	Area under crop. Acres.	Yield. Bushels.	Value. £
New South Wales .	123,517	2,511,400	345,317
Victoria	517,229	9,572,003	1,316,150
Queensland	4,010	63,912	25,565
South Australia ..	155,214	1,939,415	210,097
Western Australia	318,982	4,241,074	596,401
Tasmania	46,175	1,065,933	167,591
Commonwealth .	1,165,127	19,393,737	2,661,121

The production has not yet reached a stage that will admit of regular exports; on the contrary, in each of the four years preceding 1916-17 the imports exceeded the exports, the total excess being some 6½ million bushels, valued at over

one million sterling—chiefly from New Zealand, Chile, Japan, and the United States.

Oats are subject to two diseases only to any appreciable extent, viz. Loose Smut (*Ustilago avenae*) and the rusts (*Puccinia* spp.), though mildew, a foot-rot condition, and even 'take-all' (very rarely) have been recorded on it. The smut is controlled by spraying the seed with 1 per cent formalin solution and covering with bags for four hours; the rust can only be prevented by the use of varieties that show immunity to the disease. W.S.C.

Observatories. See ASTRONOMY.

Ocean Currents. See CURRENTS, OCEANIC.

Ocimum, a widespread genus of the family Labiatae, of which the only species indigenous to Australia, *O. sanctum* (a branching under-shrub with small purple or white flowers), is chiefly Asiatic, and derives its specific name from being frequently planted about Hindu temples. It is strongly scented, and is used medicinally by the Cingalese.

O'Connell, SIR MAURICE CHARLES (1812-1879), son of Sir M. C. P. O'Connell (q.v.), was born at the old military barracks in Sydney in January 1812, sent to England to be educated in 1819, and appointed to his father's old regiment —the 73rd—in 1828 (ensign, 1828; lieutenant, 1834; captain, 1838). In 1835 he obtained leave to volunteer for service under the Spanish crown, raised a regiment (the 10th Munster Light Infantry) to fight in the Peninsula, saw a good deal of fighting in the Carlist war, became general of the British auxiliary legion, was decorated with several Spanish orders of knighthood, and on the disbandment of the legion in December 1837 returned to England still a lieutenant. On 22 June 1838 he was commissioned captain in the 28th regiment, which was going to New South Wales, and accompanied his father there as military secretary; but when the regiment returned O'Connell sold out and remained in the colony, breeding horses and entering politics. From 1845 to 1848 he represented Port Phillip in the legislative council; then he became commissioner for crown lands in the Burnett district, and in 1854 was made government resident at Gladstone (see GLADSTONE COLONY), which the New South Wales authorities were fostering in the vain hope that it would become the chief town of the prospective colony of Queensland. For five years he administered the Port Curtis district with zeal and ability; but his desire to make Gladstone the shipping centre of central Queensland was frustrated by the foundation of Rockhampton on the Fitzroy River, a little farther north—for the Fitzroy gave direct access to large areas of the interior, from which Gladstone was cut off by much rough and difficult country.

When in 1859 Queensland was made a separate colony, O'Connell became a nominee member of the legislative council, attaining its presidency in 1861 and holding that office until his death. He took an active interest in public education, agriculture and racing, four times administered the government of the colony between governorships, and enjoyed great popularity in all his capacities. Dying in Brisbane on 23 March 1879, he was accorded a public funeral; and when it was known that he had maintained his public positions by the expenditure of all his private means, his widow was voted a pension by the legislature. (Kt. Bach., 1868.)

O'Connell, SIR MAURICE CHARLES PHILIP (1768-1848), born at Riverston in county Kerry, Ireland, and brought up mainly in France at the charges of his kinsman Count Daniel O'Connell, joined the Irish brigade of the French army in 1790, but in 1792 had a captaincy in the anti-revolutionary forces under the Duke of Brunswick, and two years later rejoined the Irish brigade as reconstructed in the British army. For the next 12 years he served with various regiments in the West Indies, gaining much credit and two swords of honour; on 15 October 1806 he was made a major in the 73rd foot, promoted to command it (as lieutenant-colonel) on 4 May 1809, and sent with its first battalion to New South Wales. Accompanying Macquarie—under whom he held a commission as lieutenant-governor—he reached Sydney at the end of 1809. At first Macquarie and he worked cordially together; but before he had been six months in the colony O'Connell married the daughter of ex-governor Bligh, and from her seems to have acquired her natural dislike of all those who had shared in the revolt against her father. By 1813, therefore, Macquarie (who had not been prepossessed with Bligh, and was anxious to have harmony restored in his little kingdom) told Bathurst that, if the O'Connells were removed, 'the remains of this Party Spirit and Faction will be Completely annihilated;' and by 1815—when O'Connell had left the colony, but was supposed to be eager for the lieutenant-governorship of Tasmania—Macquarie's memory of him was concerned only with his 'illiberal national partialities and prejudices . . . . irritable temper and overbearing disposition.'

In 1814 the 73rd was relieved, and O'Connell proceeded with it to Ceylon, retiring on half-pay when it returned to England. In 1830 he was promoted major-general, and in 1838 revisited New South Wales as commander of the forces stationed there. He became lieutenant-general in 1841, was made colonel of the 80th foot (then in Sydney) in 1844, administered the government in 1846 between the departure of Gipps and the arrival of FitzRoy, and handed over his command to Major-general Wynyard in December 1847. On the day he was to have left for England—25 May 1848—he died at his house on Potts Point, Sydney. (Kt. Bach. and K.G.H., 1834.)

O'Connor, CHARLES YELVERTON (1843-1902), born at Gravemouth in Ireland in 1843, educated at the Waterford endowed school, and afterwards apprenticed to engineering, migrated to New Zealand in 1865, and from then until 1883 was assistant-engineer and engineer for various districts in the South Island. In 1883 he became under-secretary for public works, and in 1890 was appointed marine engineer for New Zealand. In April 1891 he accepted the combined appointment of engineer-in-chief and manager of railways for Western Australia. In 1896, at his own request, O'Connor was relieved of the railways, but retained the position of engineer-in-chief until his death on 9 March 1902. His period of office in Western Australia was marked by the inception and completion of two great engineering works, the Coolgardie water-scheme and the Fremantle harbour-works. (C.M.G., 1897.) J.S.B.

O'Connor, RICHARD EDWARD (1851-1912), son of a clerk of parliaments in New South Wales, was born at Sydney on 4 August 1851, educated at the Sydney grammar school and university (B.A., 1871; M.A., 1873), and in 1871

entered the public service as a clerk in the legislative council—spending his spare time in writing for the press and reading for the bar, to which he was called in 1876. In 1888 he was nominated by Sir Henry Parkes to the legislative council. While opposing Parkes on tariff questions (for O'Connor was a convinced if moderate protectionist), he supported the old statesman in the cause of federation; and, when Dibbs in October 1891 defeated Parkes and formed a new ministry, it was only to support Edmund Barton—on whom Parkes had thrown his mantle—that he took the position of minister for justice. At the end of 1893 the two champions of federation were attacked for taking part—Barton as arbitrator and O'Connor as counsel—in an action between the colony's railway commissioners and a contractor; both resigned their ministerial positions, and the prospects of federation seemed at their gloomiest. But when in 1897 George Reid's scheme for discussing federation through a body of elected representatives from the several colonies came into effect, O'Connor found himself one of the ten from New South Wales; he was also one of the three members of the committee that drafted the constitution, and took an active part in open convention when the provisions for deadlocks were being modelled; but his most difficult and least conspicuous work was the attempt to carry through the New South Wales legislative council the various bills and resolutions needed to ensure the passage of the convention's recommendations. In the end it was found necessary to appoint 12 new members to the council.

With the advent of federation O'Connor's zeal and industry found a new sphere. Barton, with whom he had always heartily co-operated, made him vice-president of the executive council in the first Commonwealth ministry—an office which carried with it, as soon as O'Connor was elected by New South Wales to the senate, the leadership of that body. Here his bitter experience in the New South Wales council stood him in good stead, for he had to carry a protectionist tariff and the naval agreement of 1902 through a house markedly freetrade in its views and extremely suspicious (for reasons explained in the article on NAVAL DEFENCE) of the agreement. In both tasks he succeeded. But it cost him his health, and his withdrawal from politics in September 1903, to become one of the first three judges of the federal high court, was no less a necessary condition of longer life than a reward for past public service. In 1905 he was appointed first president of the Commonwealth court of conciliation and arbitration—another tribute to his tactfulness—but resigned it thankfully in 1908, and devoted his powers thenceforward mainly to the solution of the numerous constitutional difficulties which have occupied so much of the high court's time. From the excessive strain of his past political career, however, he could not wholly recover; he died of anaemia, while still in active work as a judge, on 18 November 1912.

O'Connor's value to Australia during the stormy years before and after the attainment of federation cannot be too highly estimated. Through them all he retained the admiration and affection of opponents as well as of friends; and an obituary notice in *The Times* pronounced his eulogy in terms with which no one is likely to quarrel:—

> In the cabinet he was sagacious, wise and far-seeing. In the house he was uniformly calm, courteous and courageous. . . . His political career can best be epitomized as embodying in essentials consistency, in non-essentials liberty, in all things charity. . . . On the bench he was above all things a sound constitutional lawyer, and helped to build the Commonwealth by judicial interpretation on a solid and enduring foundation.

Octopus. See MOLLUSCA.

Odonata. See DRAGONFLIES.

Officer, SIR ROBERT (1800-1879), born in Scotland on 3 October 1800 and educated at St. Andrews, migrated to Tasmania in 1821, was appointed medical officer for New Norfolk, and built up a considerable private practice. In 1853 he gave up medical work, and was elected for Buckingham to the legislative council. On the establishment of responsible government he became member for Glenorchy in the new assembly (1856). He was made chairman of committees, and in 1861 speaker, a post which he held till 1877. He took special interest in the acclimatization of salmon and trout, and it was mainly his influence that kept the vote for that purpose regularly in the budget. Retiring from public life in 1877, he died at New Norfolk on 8 July 1879. (Kt.Bach., 1879.)

O'Flaherty, ELIZA (1818-1882), better known by her maiden name of Winstanley, born on 1 September 1818 in Kent-street, Sydney, began her stage career on 31 October 1834, when she appeared as Clari in the *Maid of Milan*. For the next ten years she was the leading actress in Sydney, being successful both in tragic and comic rôles. In 1845 she and her husband, Henry Charles O'Flaherty, a musician whom she married in 1841, left the colony for England, France, Russia, and Germany. In 1848 she appeared at the Astor Place Opera House, New York, where she played Mistress Quickly to James Hackett's Falstaff. On her return to England she joined Charles Kean's company at the Royal Princess's Theatre and continued with him when he toured the provinces. She was especially successful in Shakespearean plays, and was noted also for her singing. Her portrait is included in J. O. Halliwell's edition of Tallis's *Portrait Gallery of Distinguished Actors and Actresses of the Fifties*. About 1865 she gave up the stage for literature and wrote many Australian stories, some of which were published serially in the journal *Bow Bells*, which she edited for some years. Her better-known works include *Desmoro: or The Red Hand*; *Twenty Straws*; *For Her Natural Life* (written before Marcus Clarke's novel); and *Bitter Sweet* (which she published serially in the *Sydney Mail* in 1860). Some of her stories, which number altogether about 33, were published under the pen-name of 'Ariele.' About the end of the seventies she returned to Australia and died at Sydney on 2 December 1882.

Ogilvie, WILLIAM HENRY, born near Kelso, Scotland, on 21 August 1869, was educated at Kelso high school and Fettes College, Edinburgh. Coming to Australia in 1889 he engaged in droving, horse-breaking, and kindred occupations 'out-back' in New South Wales. He returned to Scotland in 1901, went thence to Iowa, U.S.A., edited an agricultural paper there, and in 1908 returned again to Scotland, where he still resides; much of his time is devoted to freelance journalism, and he is now regarded as a genuine 'Scottish bard.' It is however, by his Australian work that Ogilvie will be best remembered; in popularity his *Fair Girls and Gray Horses* proved second only to Pater-

son's *Man from Snowy River*. Ogilvie was, indeed, another Paterson, in that he loved the free life of the wide spaces and sang of its charms in rollicking ballads (e.g. 'From the Gulf') which go with a swing; but he touched the hem of the higher poesy (as in 'Bowmont Water') rather more often than his contemporary and used a wider sweep by reason of his Scottish associations and the fact that Australia was to him a big new adventure; he could also sing of babyhood (as in the widely known verses 'A King Deposed'). During the great war he published in London *Punch* a verse-tribute to the 'Anzac' as 'the bravest thing God ever made.'

He has published in verse: *Fair Girls and Gray Horses* (Sydney, 1899); *Hearts of Gold* (Sydney, 1901); *Rainbows and Witches* (London, 1907); *Whaup o' The Rede* (Dalbeattie, 1908); *The Land we Love* (Dalbeattie, 1910); *The Australian* (Sydney, 1916); *Galloping Shoes* (London, 1922); *Scattered Scarlet* (London, 1923); *Over the Grass* (London, 1925); and in prose: *My Life in the Open* (London, 1908); *The Honour of the Station* (London, 1914).

O'Halloran, THOMAS SHULDHAM (1797-1870), son of Major-general Sir Joseph O'Halloran, was born at Berhampore in India on 25 October 1797, and in 1808 entered as a cadet at the Royal Military College—then at Marlow in Buckinghamshire, but removed to Sandhurst in 1812. He joined the army in 1813 (ensign, 1813; lieutenant, 1817; captain, 1827), and saw service in the Nepal, Deccan, and Burmese wars between 1814 and 1825. Retiring in 1838, he sailed with his family for South Australia and reached Adelaide on 21 November; in February 1840 he was appointed major commanding the local militia, and in June of the same year became commissioner of police, and undertook several expeditions against thieving or murderous aborigines. He resigned the commissionership in 1843, and was nominated to the legislative council as a non-official member. When in 1851 the first instalment of representative government was granted, he contested two elections unsuccessfully; but when the constitution of 1857 came into force he was returned at the head of the poll for the new council, and held the seat until his retirement from politics in June 1863. In 1854 he was gazetted lieutenant-colonel of the local volunteer force. He died at his home near Adelaide on 16 August 1870.—His younger brother WILLIAM LITTLEJOHN O'HALLORAN (1806-1885), also born at Berhampore on 5 May 1806, joined the army in 1824 (ensign, 1824; lieutenant, 1826; captain, 1837), saw active service at the siege of Bhurtpore (1825-6), served in India (1824-29), Ireland (1832-4), and India again (1835-6), visited Sydney with a detachment of his regiment (the 50th) in 1834, and retired from the army in 1840. On 11 August of that year he reached South Australia, where he was private secretary to Governor Grey (1843-5) and auditor-general of the colony (1851-68). He died at Adelaide on 15 July 1885.—William's son, JOSEPH SYLVESTER O'HALLORAN (1842-1921), born at Adelaide on 28 March 1842, after a long career in the public service of the colony which ended in 1871, spent ten years in secretarial work in London and in travel, and in 1881 was appointed assistant-secretary to the Royal Colonial Institute; in 1884 he was made secretary, and held the position until 1909. He died on 29 January 1921. (C.M.G.,1895.)

Oil. This article deals with mineral oils, of which no liquid deposits have yet been found in Australia; modern prospecting methods have, however, been employed only since 1917. In 1920 the Commonwealth government offered £50,000 for the discovery of commercial oil-pools in the Commonwealth; in 1925 this offer was withdrawn, and was replaced by a proposal to subsidize on the £-for-£ basis *bona fide* companies operating in areas approved by the government's advisers. Meanwhile, under an agreement with the Anglo-Persian Oil Company made in 1920, the company supplies, at current rates, the Commonwealth oil refinery at Laverton in Victoria (in which the government holds a bare majority of shares) up to 200,000 tons of crude oil a year from its Persian fields. Outside this agreement Australia imports oil to the value of about £7,600,000 annually from the Dutch East Indies, California, Pennsylvania, and the mid-continental fields of the United States.

The geological history of Australia suggests that the conditions of sedimentation and earth-movement controlling the formation, migration, and accumulation of petroleum into commercially valuable oil-pools of Tertiary age—as found in the world's principal oil-belts, connected with the Tethys, Malaysian, Antillean, Pacific, Alpine, Caucasian, and similar mountain zones—did not extend to Australia. Any Australian oil-fields of commercial value would belong to Mesozoic or Palaeozoic formations, and it is in the Walloons (Jurassic) of Queensland and the Kimberley (Permo-Carboniferous) beds of Western Australia that geologists have seen possibilities of oil-discoveries. Up to the present time, however, prospecting indicates that the great Meso-Palaeozoic region of Australia is comparable to peninsular India, South Africa and Brazil, none of which have yet been proved to contain oil deposits.

Positive indications that oil exists in Australia, commercially or otherwise, are:—(*a*) Asphaltum of great purity is periodically washed up on the southern shores of the continent. This inspissated petroleum must be derived either from the coastal rocks or from their faulted extension (the 'continental shelf'); it has been thought to warrant prospecting in the Tertiary measures of southern Australia, if structurally favourable areas can be discovered. So far only one definite 'dome' structure has been located—at Comawn in Victoria, where a private company is boring. (*b*) Bitumen fragments, highly metamorphosed and approaching coal in their characteristics, have been discovered filling vesicles in basalt and in the associated limestone joints in Cambrian rocks of the Ord-Negri district of north-western Australia, as well as in the Cambrian shales of Elcho Island in the Northern Territory. (*c*) Natural gas of the 'wet' type has been met with in large quantities in artesian bores sunk in the Roma district of Queensland, and at Grafton in New South Wales. 'Dry' natural gas was also struck at Lake Bunga in eastern Victoria, in a bore sunk to test the Tertiary deposits of the district for oil. (*d*) Oil of a light nature was struck at 70 feet in a water-bore at Beaudesert in Queensland, and heavy waxy oil at great depths in artesian bores sunk in the Longreach and Blackall districts of the same State.

On the other hand, many hundreds of prospecting bores for coal, oil-shale, water, and minerals have been sunk throughout Australia, without encountering anything more than traces of oil—or sometimes copious quantities of gas.

So far as the more accessible southern and eastern parts of the continent are concerned, the consensus of opinion is that, if oil does occur there, it does so under conditions differing entirely from those in other parts of the world. The great north-western areas of thick Palaeozoic sediments, often highly fossiliferous, which dip gently off the Archaean shield 'nucleus' and thus suggest a resemblance to the Palaeozoic formations in the oil-belts of the eastern and mid-continental fields of North America, are only in the initial stages of prospecting.

In *New South Wales* bores for oil have been sunk at Penrith, Coonamble, and Grafton—with negative results, except for gas at Grafton; the rocks penetrated were mostly horizontal or gently dipping Mesozoics, although spasmodic bore-sinking for oil has been undertaken in rocks of Permian, Devonian, and Silurian ages.

The folding movements which closed the Permian period in Australia affected a narrow strip in the eastern part of the continent extending from the Hunter River in New South Wales to northern Queensland. Recommendations for boring on the Hunter River areas—notably on the Belford 'dome' structure—have been made by Dr. A. Wade, and companies are being subsidized by the Commonwealth government to undertake the work. The favourable opinion of the Hunter River region as oil-producing is based chiefly on the existence there of a 'dome' structure, but the problem is complicated by faulting and lack of knowledge of the nature of the marine fauna from which the oil might have originated.

In *Queensland* natural gas was accidentally struck at 3683 feet in an artesian bore at Roma in 1900, and unsuccessful efforts to light the town from this supply were made four years later. Thenceforth until 1916 efforts to tap and utilize the gas were made, with more or less disastrous results. In 1916 the state government began to prospect for oil, but met with a series of misfortunes in drilling; it was, however, demonstrated that the gas discharged was of the 'wet' or petroliferous type.

In 1922 a private company commenced operations with a modern plant at Orallo, near Roma, where Dr. H. I. Jensen had reported favourably upon the prospects for commercial oil. The results hitherto have been disappointing, partly because of drilling accidents, largely because of water troubles in the bore. Dr. Wade has reported unfavourably on the Beaudesert, Tewantin, and Wolston areas, but has recommended further prospecting in the rocks of the Queensland artesian basin and its intake-beds.

South Australia.—Prospecting has been done on the coast and inland, not only in moderately deep Tertiary rocks, but also in the closely-folded schists of Archaean age, where the occurrence of oil is impossible. Bores have been put down at Kingston, Robe, Tantanoola, Mount Gambier, the Coorong, and the Glenelg River, in all cases with negative results; the deepest bore (at Robe) penetrated over 3000 feet into the Jurassic strata before being abandoned.

Victoria.—Prospecting in the gently domed or warped strata of Tertiary age at Torquay in Gippsland, and in the brown coal-measures of that region, have yielded negative results; the beds, however, are crowded with marine fossils of all kinds, including the 'oil'-type foraminifer *Orbitoides lepidocyclina.* Natural gas of the 'dry' type was struck at 900 feet in a bore at Lake Bunga, and flowed intermittently.

Tasmania.—No definitely favourable indications have been met with in this State, though large sums have been spent in boring the highly faulted and tilted Permo-Carboniferous rocks of the Mersey valley. Rocks of the Tertiary fringe have not yet been prospected for oil.

Western Australia.—Several moderately deep bores have been sunk in the Kimberley division, chiefly because of the presence of bitumen in the Ord-Negri area and of small oil 'seeps' in a bore at Price's Creek. The sites were selected in gently folded Cambrian and Carboniferous rocks, but oil in commercial quantities has not yet been discovered.

Briefly summarized, the search for oil in Australia has yielded only small traces of petroleum products, and quantities of natural gas, in places which otherwise present the 'requisite and essential conditions for the occurrence of oil.' This clearly indicates that earth-movements and underground-water conditions which have affected the continental rocks from Palaeozoic times (at the close of which general 'folding' movements ceased in Australia) have not caused accumulation of the oil-contents of the rocks into suitable reservoirs, whereas erosional agents have helped to dissipate any oil deposits that might have been formed previously.

Papua and the Mandated Territory.—New Guinea is an integral part of the so-called Malaysian 'arc' zone—which embraces the oil-producing islands of the Netherlands Indies, and which has been subjected to the same folding movements in late Tertiary times; the prospect of locating commercial oil-pools in the Tertiary rocks of Papua and the Mandated Territory is therefore hopeful, though exploratory drilling results so far have produced only about 2000 gallons of crude petroleum. Oil and gas seepages are numerous, especially in the coastal portions of Papua, where most of the boring operations have been conducted.

The oil-measures of Papua occur in a late Tertiary series of fossiliferous mudstones, sandstones, limestones, and marls, associated here and there with lignite and carbonaceous sediments. The upper measures are Pliocene to recent, the lower Plio-Miocene; their total thickness is from 3000 to 7500 feet. In the Mandated Territory similar measures occur, of an estimated total thickness up to 15,000 feet, but distributed over a much smaller area.

Prospecting was initiated in the Vailala River district of Southern Papua by the Commonwealth government in 1912, and continued under great difficulties until 1919. In the interim eight shallow bores and one moderately deep one (1800 feet) had yielded 2000 gallons. Running muds and high gas-pressures gave great trouble in the drilling, but the quality of the oil was very high.

The Anglo-Persian Oil Company, acting as agent for the British and Commonwealth governments, who jointly financed the operations, took over control in 1920. Its experts considered that the wells sunk on the Vailala area were located in ground too highly faulted to justify hopes of commercial oil-yields; after much geological surveying of the Gulf-coast region from Yule Island to the Vailala River, a site for boring on an undisturbed anticline at Popo near the Kapuri River was selected, and drilling commenced in 1922. Difficulties in dealing with soft flowing mudstones led to the abandonment of this bore at 1825 feet, and of a second one at 894 feet; a third bore met with heavy caving strata at 2375 feet, and the boring tools were buried. The estimated depth of the oil

horizons in the Popo district is from 2000 to 3500 feet in Plio-Miocene beds.

In 1923 private oil-prospecting companies were allowed access to Papua—except in an area of 1160 square miles including the Popo district—and a number of licences have been issued. Prospecting work and geological surveying are proceeding on some of the licensed areas, but up to June 1926 no results of importance were obtained.

In the Mandated Territory oil seepages have been reported from time to time, and geological surveys have been made by the staff of the Anglo-Persian Oil Company, the government geologist, and privately. Shallow bores have been sunk at Matapau, near Aitape, and at Marienberg on the Sepik River, and small quantities of oil of good quality reported. Farther inland, notably in the Sepik and Ramu valleys, geological conditions are more favourable. Oil-search licences are issued to private companies; licensees have the exclusive right to prospect an area up to 1000 square miles in extent for a term of five years (renewable); should petroleum be struck, they may take up oil-leases of four square miles each for 21 years (renewable), paying a royalty to the crown of 2½ to 5 per cent on all oil won.

Oil-shale. *New South Wales.*—Large deposits of high-grade kerosene-shales (torbanites) are found in the Permo-Carboniferous measures of New South Wales, notably in the Wolgan valley near Capertee, in Hartley Vale below Mount Victoria, at Murrurundi in the Hunter valley, and at Joadja near Mittagong. Similar shales occur in the coal-measures of the Mersey River district of Tasmania, and in the Tertiary and Carboniferous rocks of Queensland. The origin of the torbanites has been proved to be due to the local accumulation in basins of showers of minute spores (sporangia), algae, and seeds, with an admixture of peaty material from the swampy ground in which the associated coals were formed. Many rhizomes of *Glossopteris* in the growing position, Entomostraca shells, and other fossils have been isolated from the deposits.

The richer varieties of kerosene-shale resist weathering, and closely resemble the true cannel coals. They may be regarded as the middle members of a series including true oil-shales and cannel coals as the extremes; the less coaly torbanites grade downward into oil-shales proper, and the more coaly upward into the cannel coals. Original conditions of deposition, and the subsequent metamorphism of the sediments containing the shaly raw material, determined whether the final product would be true oil-shale, torbanite, or cannel coal. The earth-movements necessary to the actual distillation and storage of oil did not subsequently occur, so that the deposits are still in the solid oil-shale stage, and invariably occur in lenticular form over limited areas (rarely exceeding one to two square miles in extent) and of a thickness of up to 5-6 feet of workable shale. Physically the torbanites resemble closely the typical Cretaceous and Tertiary shales of Colorado in the United States, but they contain more volatile matter, and consequently yield more oil and gas.

As mined, the New South Wales torbanites contain from 40 to 77 per cent of volatile hydrocarbons; the best types range from 57 per cent upwards. Ash, sulphur, nitrogen, and oxygen are usually low, so that the resultant distilled oil is very pure and closely resembles a typical crude paraffin-petroleum. As much as 150 gallons of oil per ton has been obtained, but a fair average yield from commercial plants which have been in operation in the past may be taken as from about 80 to 100 gallons.

The discovery of oil-shale in New South Wales dates back to 1802; its occurrence in Hartley Vale was noted in 1845, and mining began in 1865, the shale being chiefly exported for gas enrichment. By the close of the 19th century crude oil-retorting works were established on the fields, mostly on a small scale and in a primitive manner. In the first decade of the present century large retorting plants and refineries were established at Joadja, Newnes (in the Wolgan valley), and Murrurundi; these were financed in most cases by English capital and were based on the Scottish system of retorting, which was afterwards proved unsuitable to Australian conditions. The Joadja mine was closed down in 1905, but was reopened in 1925. The Newnes works of the Commonwealth Oil Corporation of London, the largest and most ambitious shale-retorting company in Australia, closed down in 1914, and the British-Australian Oil Company's mine at Murrurundi closed a year later. The old plant of the Commonwealth Oil Corporation was taken over by a Sydney company, modified Pumpherston retorts were erected, and the plant operated until 1922. The total production of crude oil during that period was approximately 12,800,000 gallons, on which a bonus amounting to 3d. per gallon was paid by the government. The quantity of shale mined in New South Wales is 1,919,043 tons—of which less than 10 per cent was actually retorted, for a total production of 13,000,000 gallons of oil.

It is now certain that both retorts and methods of use must be adapted to the specific shale treated, with due regard to local conditions. Scottish retorts of the Pumpherston type, even when modified, are unsuited for dealing with New South Wales torbanites—which, unlike the Scotch shales, are rich in 'kerogen' and low in nitrogen. Bronder and Crozier retorts are being used on local shales in both New South Wales and Tasmania.

Queensland.—Work on a commercial scale has not been undertaken in this state, but workable shales of medium quality have been discovered in the Tertiary measures of Curtis Island near Rockhampton. Torbanites are found at Baffle Creek and Duaringa in the Leichhardt district; types similar to those of New South Wales also occur on the Queensland slopes of the Macpherson Range.

Tasmania.—Tasmanite, a torbanitic shale of somewhat inferior quality occurs—in tens of millions of tons and in thicker workable seams than those of New South Wales—over a large area on both sides of the Mersey River in the lower Permo-Carboniferous coal-measures. Attempts to work these deposits in the past have been unsuccessful, but two small companies produced oil at the rate of about 40 gallons per ton of shale retorted; the oil was refined in Melbourne. A large private company is erecting huge works in the Mersey valley to treat up to 1000 tons of tasmanite per day by the Bronder process; the oil-yield is only about half of that from New South Wales torbanites, and injurious sulphur compounds are invariably present in the tasmanite oil, yet it is considered that lower mining costs and easier methods of treatment will more than compensate for this difference.

J.L.S.

Olacinaceae, a family of trees, shrubs, and climbing plants widely dispersed over tropical and subtropical regions. The flowers are usually small. Nine genera are indigenous to Australia. The genus *Olax,* which extends over tropical Asia and Africa, contains five Australian species —four are eastern, but *O. Benthamiana* reaches Western Australia. *O. stricta,* an erect, slender shrub, has the leaves arranged in opposite pairs, and branches ranked in a few rows, giving the plant a flattened outline. The creamy flowers are much frequented by bees, and the green fleshy fruits are greedily devoured by poultry. The genus *Pennantia* has one representative in Norfolk Island and one in New Zealand; *P. Cunninghami* is endemic in Australia; it is a tall shrub, with large ornamental leaves and black-berried fruits. Remarkable structures known as domatia (q.v.) are found on the leaves of this species.

Old Age Pensions. See PENSIONS.

Old Wife, a small fish (*Enoplosus armatus*) very common in inlets on the coasts of the southern half of Australia, and well known by its striking colour-marking, which consists of broad dark-brown bands on a white ground, and fins banded with brown and pink. It was one of the first fishes made known from Australia, being illustrated in Surgeon White's *Voyage to New South Wales,* published in 1790. It is a tasty little table-fish, but is rarely utilized; it seldom exceeds eight or nine inches in length, and, unless taken with the trammel net, does not often appear in the markets. A.R.McC.

Oleaceae, a small family of trees, shrubs, climbers, or herbs found in warm to temperate regions. Five genera with 24 species are indigenous to Australia. The flowers are usually in clusters; fruit a succulent drupe or dry capsule. The genus *Jasminum* has seven indigenous species, with white or yellow flowers; some are highly ornamental sweet-scented shrubs. *Olea paniculata* (Native Olive) the only indigenous species of its genus, extends to New Caledonia. It is a moderate-sized tree, with a succulent drupe resembling that of the common olive. The wood when newly cut has a rose-like fragrance. The heart-wood is nicely mottled, tough, durable, and suitable for turnery. See CHIONANTHUS, NOTELAEA.

Olearia, a genus of the family Compositae, consisting of herbs and shrubs (rarely small trees) with white or blue flowers. They are often called 'native asters,' and are closely allied to the old-world genus *Aster.* The floral bracts are imbricate, in several rows; marginal florets rayed; fruits usually cylindrical, with the pappus bristles in a single row. *O. argophylla* (Musk Tree), grows in Tasmania to a height of 20-30 feet with a trunk-girth of 3 feet; in Victoria and on the south coast of New South Wales it attains almost the same size. The silvery leaves are musk-scented. The timber has a pleasant fragrance; its gnarled root-stock is mottled, and is well adapted for cabinet-making. *O. myrsinoides,* a very variable species, is also musk-scented; *O. ramulosa,* a heath-like shrub, is covered in the season with a profusion of small white flowers; in *O. dentata* the flowers range from white to pink and blue, occasionally on the same plant.

Olive, a name applied (*a*) to the cultivated

1868. After ten years' practice in England he

GROWING, (*b*) to certain Australian trees and shrubs of the same family, for which see OLEACEAE and NOTELAEA.

Olivine. See MINERALOGY.

O'Loghlen, SIR BRYAN (1828-1905), third son of a distinguished Irish judge who was created a baronet at the coronation of Queen Victoria, was born on 27 June 1828, educated at Oscott and at Trinity College, Dublin (B.A., 1856), and after making trial of engineering, farming, and commerce was called to the Irish bar in 1856. Migrating to Melbourne (which he reached in January 1862), he was called to the Victorian bar and practised his profession assiduously for the next 15 years. In May 1877 he plunged into politics as an advanced liberal and a supporter of Graham Berry, and after one defeat was elected for West Melbourne in February 1878 and made attorney-general in the Berry ministry in March; meanwhile, however, he had (on 22 July 1877) succeeded his elder brother in the baronetcy and been elected to the British parliament as member for county Clare. On his acceptance of office under Berry the Irish seat was declared vacant.

O'Loghlen took office in the midst of the turmoil that followed 'Black Wednesday' (q.v.), which is fully described under BERRY, SIR GRAHAM; it would seem that even before his appointment he had advised the governor that the ministry's action was strictly in order. He supported Berry through thick and thin, and was given the post of acting-premier while the Berry-Pearson delegation visited England. The 1880 elections left him without a seat; the Berry ministry resigned immediately after them; when it was re-formed (after a second set of elections, in which O'Loghlen gained the West Bourke seat), he found himself left out. Consequently in July 1881, as soon as the dispute between council and assembly had been temporarily settled, he displaced Berry from the premiership and himself formed a ministry that lasted until March 1883, never possessing a genuine majority, but maintained in office by the conservatives in order to exclude Berry. An extravagant policy of railway construction and the imposition of a poll-tax on immigrant Chinese were the two principal achievements of this ministry, which was heavily defeated at the elections of 1883 and was succeeded by the famous Service-Berry coalition. O'Loghlen himself lost his seat and, though he soon afterwards became member for Belfast and in 1890 helped James Munro to turn out the Gillies-Deakin coalition, returned to office in 1893-4 only as attorney-general under J. B. Patterson. When this ministry was expelled in September 1894, O'Loghlen retired from active political life—though in 1897 he appeared as vice-president of an 'Anti-Commonwealth-Bill League,' having been a steady opponent of federation. He died in Victoria on 31 October 1905.

Onion, Wild. See BULBINE.

Onion-wood. See DYSOXYLON and OWENIA.

Onslow, SIR ALEXANDER CAMPBELL (1842-1908), was born on 17 July 1842 at Ripley in Surrey. His mother was a daughter of Alexander Macleay (q.v.). Educated at Westminster School and Trinity College, Cambridge (B.A., 1864), he was called to the bar on 17 November 1868. After ten years' practice in England he

was in 1878 appointed attorney-general of British Honduras. In 1880 he was transferred to a similar position in Western Australia, where in 1883 he became chief justice. In this capacity he administered the government of the colony during the temporary absence of Sir F. Napier Broome, and was later 'interdicted' by that governor for premature publication of official correspondence. The local executive council confirmed this suspension and placed the judge on half-pay; but Lord Knutsford, then colonial secretary, reinstated him with a rebuke. A later quarrel with the legislative council (which asked for his removal 'in the interests of tranquillity') led to his temporary supersession by Sir Henry Wrenfordsley (q.v.); but he resumed his position in 1891 and held it for another ten years. Retiring in 1901, he died in England on 20 October 1908. (Kt.Bach., 1895.)

Onslow, Arthur Alexander Walton (1833-1882), son of A. P. Onslow of the East India Company's service, was born at Trichinopoly in India on 2 August 1833, brought to Sydney in 1838 to stay with his grandfather Alexander Macleay, taken to England in 1841 by the widow of Colonel Dumaresq, and entered on board H.M.S. *Howe* as a midshipman in May 1847 (lieutenant, 1852; commander, 1863; post-captain, 1871). He served in the Channel and Mediterranean squadrons and off the west coast of Africa (1850-1); during the Crimean war he was employed in the Baltic, being present at the bombardment of Sveaborg, and in March 1857 sailed for Australia, where for the next four years he was engaged in a survey of Shark Bay, Torres Straits, and the external reefs of the Great Barrier. Returning to England in 1861, he served in the Gulf of Mexico and the Mediterranean, but was compelled by bad health to leave the service and reside in Sydney, where in 1867 he married James Macarthur's eldest daughter and founded the family of Macarthur-Onslow. In 1874 he accompanied William Macleay in an exploration along the New Guinea coast. Entering local politics in 1869, he represented Camden in the assembly until 1880, when he was appointed to the legislative council. He died on 31 January 1882.

Opal, a mineral consisting almost entirely of hydrated silica, which occurs in two main forms. *Common opal* is usually colourless or milky, but is sometimes banded, or coloured red, green, or pink by absorption of organic matter. The opal from certain deposits, however, displays by reflected light brilliant flashes of colour which are due to structural peculiarities in the stone; this is known as *precious opal,* and it alone is discussed here.

Of Australian opals there are four recognized varieties—boulder opal, sandstone opal, seam opal, and black opal. Boulder opal was first discovered in Queensland about 1875, and was introduced to the London market about 1879, but with little success. It occurs in veins ramifying through ironstone boulders, and in layers so thin that the cut stone (which is very brilliant in colour) must be left with a flat face and a backing of matrix. Similar opal was discovered in 1877 at Rocky Ridge Creek on the Abercrombie River in New South Wales, where it occurs in vesicular basalt; but specimens suitable for jewellery are rarely obtained there, and the deposits have not been worked commercially. West of Cunnamulla in Queensland boulder opal is found in minute boulders known as 'Yowah nuts,' which sometimes contain the usual thin veins and sometimes loose kernel-like gems. Sandstone opal, which was discovered in Western Queensland about 1886, usually occurs as pipes of varying diameter from an inch downwards; the sandstone through which they run overlies in patches the great Rolling Downs formation of western Queensland (see Geology). Sandstone opal is as a rule thick enough to be cut cabochon shape; the introduction of these stones to the London market (which took place in 1889) was successful, and from that time Australian opal has been reckoned among valuable gems. The sandstone opal area is a belt of western Queensland about 250 miles wide, extending about 550 miles north-west from Hungerford on the New South Wales border to Kynuna at the head of the Diamantina River.

In 1889 a kangaroo-hunter picked up at White Cliffs in western New South Wales a brilliant piece of opal lying on the surface. The neighbourhood was at once prospected, and large deposits of a new kind of opal—seam opal—were uncovered, besides opalized shells, fossil bones, and bunches of crystal that the miners called 'pineapples.' This opal is free of matrix, and occurs either as flat cakes up to 7 oz. in weight or as lumps, some of which have weighed 50 oz. White Cliffs opal soon became popular in Europe and the United States; although the milky Hungarian opal was traditionally the finest procurable, the superior brilliancy of the Australian product appealed to wearers of jewels, and in 12 years the White Cliffs output attained a value of over 1½ millions sterling. In 1903, when the supply was beginning to dwindle, two prospectors along the upper Darling struck opal at Lightning Ridge near Walgett. This type was distinguished by the black body-ground in which the colours gleamed, a normal opal's body-ground being colourless or milky; for some years the new variety was difficult to market, specimens fetching only £1 or £2 per ounce, at a time when the White Cliffs product was selling at prices up to £50 per ounce. By 1910, however, Lightning Ridge was yielding two-thirds of the Australian output, and in 1914 80 per cent of it, White Cliffs having been practically abandoned. In 1915 a new field was discovered in the Stuart Range west of Lake Eyre in South Australia. This produces chiefly a light opal identical with the White Cliffs stone, but occasional specimens (in no way related to the true black opal) show an inky colouring matter. The trade depression of recent years has limited the opal market, and the lack of permanent water at the Stuart Range (Coberpedy) field has simultaneously restricted its output; no production was recorded there in 1922 or 1923, and in New South Wales only £3040 worth was won (all but £40 worth from Lightning Ridge), and in Queensland £500 worth, but these figures cannot be absolutely relied upon as parcels of stone are often disposed of privately and not recorded. Small quantities are found in the Beechworth district of Victoria.

See T. C. Wollaston's *Opal* (1924) and Pittman's *Mineral Resources of New South Wales* (1901).

Opossums. This name, borrowed from the North American Indians and applied to the American marsupial family Didelphyidae, has been almost universally adopted in Australia for certain members of another and widely different family (Phalangeridae). This is a family of diprotodont marsupials almost exclusively arboreal in habits and vegetarian in diet, both

pairs of limbs being adapted for grasping and climbing among the branches of trees. The family includes the koala (native bear), opossums or phalangers (in the narrower sense to be here considered), cuscuses, flying opossums or Australian flying squirrels, dormouse opossum, pigmy flying opossum, and long-snouted honey-mouse.

Of phalangers proper by far the commonest and best-known is the Common Australian Opossum (*Trichosurus vulpecula*), which occurs all over Australia except on the Cape York Peninsula. Of the size of a large cat, it has close, soft, woolly fur of a brownish-gray colour above; whitish or yellowish below; blackish round the eyes, on the sides of the snout, and on the chin; and black at the terminal part of the tail—which sometimes has a white tip. The outer sides of the limbs are like the upper surface, the inner like the lower; the hands and feet are white,

Common Gray Opossum
(*Trichosurus vulpecula*).

gray, or brown. The ears are rather long, erect and pointed, hairy behind; the eyes wide apart; the snout short and sharp; the upper lip deeply cleft. The fore- and hind-limbs are nearly equal in development. The fore-limb has five nearly-equal digits, all with strong claws. The hind-limb has the first toe opposable, thumb-like, to the other toes, the second and third bound together (syndactylous), the fourth and fifth nearly equal. The tail is long and prehensile, naked of hair on the lower surface for the last three to six inches of its length, and naked all round at the extreme tip. The pouch of the female is shallow.

The common opossum is an expert climber, and makes constant use of its prehensile tail in maintaining itself securely among the branches. When followed and pressed by a climbing enemy, it relaxes the hold of hands and feet and drops so as to be suspended by the tail only. Like the majority of marsupials it is nocturnal, and during daylight sleeps in the interior of a hollow tree or similar cavity; in country where trees are too small it may live in burrows. Its food consists mainly of the leaves of certain eucalypts; but leaves of other trees, fruits, and an occasional small bird or reptile may be added. The female brings forth once a year two young, which remain for a long time in the pouch, and are afterwards carried about on the back of the mother. Two sub-species have been described from the mainland, *Trichosurus vulpecula arnhemensis* from the Northern Territory, and *T. v. eburacensis* from northern Queensland. The Tasmanian variety (*T. v. fuliginosus*) is a little larger than the mainland form, and has thicker and darker fur, which is brown. A second species, the Short-eared Opossum (*T. caninus*), occurs in southern Queensland and New South Wales.

Nearly related to the common opossum are the cuscuses (*Phalanger*); but the latter have comparatively harsh fur, short ears, and a tail naked for some distance at the end. The Spotted Cuscus (*P. maculatus*) occurs in the Cape York Peninsula, and is found also in Papua and over the whole Austro-Malayan region. Another species, the Gray Cuscus (*P. orientalis*), is found in Timor, and various other islands east of Papua, including the Bismarck Archipelago, Duke of York Islands, and New Britain. *P. ornatus* inhabits the Gilolo group of islands (Ternate and others), *P. celebensis* occurs in Celebes and Sangir, and *P. ursinus* in Celebes only. A small species *P. breviceps*, is restricted to islands of the Solomon group, and another insular species occurs in the Aru Islands. Three additional species, *carmelitae*, *coccygis*, and *sericeus* have recently been described from New Guinea.

The ring-tailed opossums (*Pseudochirus*) are smaller than the common opossum, and have thinner fur. The two inner toes of the fore-foot are opposable to the other three. The tail is long and tapering, and highly prehensile, being towards the end naked underneath. The Common Ring-tailed Opossum (*P. laniginosus*), found in southern Queensland, New South Wales, Victoria, and South Australia, is of comparatively large size, the head and body being about 16 inches in length, the tail about 14 inches. The general colour of the upper surface is gray or rufous,

Ring-tailed Opossum
(*Pseudochirus laniginosus*).

that of the lower surface white, grayish-white, or rufous. A somewhat similar but darker species (*P. peregrinus*), first collected by Captain Cook's party at the Endeavour River, inhabits north-eastern Queensland. Another species (*P. dahli*) is a peculiar short-tailed, rock-living form, which

is found in the Northern Territory. Other species are the Western Ring-tail (*P. occidentalis*) of Western Australia, the Tasmanian Ring-tail (*P. cooki*), also the recently described *P. cervinus* from the Atherton Tableland in northern Queensland. Archer's Ring-tail (*P. archeri*), the Herbert River Ring-tail (*P. herbertensis*), and the Sombre Ring-tail (*P. lemuroides*) are all from the Herbert River district in Queensland. At least 10 species have been described from New Guinea.

The striped opossums (*Dactylopsila*) are more nearly related to the flying opossums though they have no flying membrane. W.A.H.

The name 'possum,' by which the opossum is commonly known in Australia, has been accepted by naturalists in view of the differences between this Australian marsupial and the true opossums of America. [A parallel acceptance of a corrupted name is to be found in 'goanna' (see LIZARDS), applied to a lizard (*Varanus*) often incorrectly termed 'iguana' because of its passing resemblance to the American reptile of that name.]

For a number of years the fur of the common opossum has been in great demand throughout the world. This has led to vast destruction of the species in the eastern States, especially in Queensland, where the total officially recorded as killed in one year has run into several millions. During the last few years, notwithstanding the incentive of greatly enhanced prices there has been a steady falling off in the killing. Complete figures are not available, but in Queensland the number of skins officially recorded in 1919 was 2,500,000; in 1923 it was 1,200,000. In Victoria during an 'open' season of only two months in 1926 no fewer than 470,000 skins were taken. It is, however, recognized that the official figures in all probability fall far short of the number actually taken, and many skins are known to be sent in with rabbit pelts. Unfortunately the greater part of the destruction takes place in the winter months, when the fur is thicker and of better quality. As this is also the time when the young are being carried in the pouch, it is clear that complete extinction of the opossum will ensue unless large areas are effectively maintained as sanctuaries.

It is often said that the opossum does damage to crops; but such statements are generally found to be baseless; they mostly spring from a desire to get the skins for commercial purposes. Undoubtedly a certain amount of damage is done to fruit-crops in parts where the opossum is plentiful, but such damage is much exaggerated; fruit-growers in the metropolitan district of Sydney successfully grew large crops at a date when the opossum was exceedingly abundant in the vicinity.

Movements for the preservation of the animal have received much support in the eastern States from pastoralists and stock-raisers, not for its own sake, but because of the widespread illicit employment of pellets of cyanide of potassium laid for it, and the consequent destruction of large numbers of horses, cattle, and sheep.

Orchids, the vernacular name of a family of monocotyledonous herbs comprising about 550 genera and approximately 20,000 valid species, practically cosmopolitan in their distribution—although as a rule they avoid extremely dry or extremely cold conditions. In tropical areas they are usually epiphytal—i.e. they grow on trees and obtain nourishment from the air. Epiphytes have been found as far south as Stewart Island in New Zealand (47° S. lat.), and terrestrial forms (those that grow from roots in the earth) occur in the tropics: but the general rule is that tropical orchids are epiphytal and extra-tropical orchids terrestrial.

In Australia the order is represented by 65 genera and about 450 valid species: but the botanical survey of the continent is still very incomplete, the Northern Territory in particular being almost unknown botanically. Of these species rather less than a third are epiphytes, confined to the tropical and eastern portions of the Commonwealth (including Tasmania); no epiphytes have been found in South Australia or in the extra-tropical area of Western Australia. Terrestrial species are capable of adapting themselves to more variable conditions of soil and climate, and have therefore a much more extensive range. For most an annual rainfall of at least 10 inches appears essential, but a few species of *Caladenia, Thelymitra,* and *Pterostylis* have been found in the arid regions of South Australia, and even in the Great Victoria Desert. A table showing the distribution of Australian orchids is given at the end of this article.

Twenty-three genera are essentially Australian; of the 274 species comprised in them 262 are believed to be endemic. The remaining genera have been derived from tropical Asia, undergoing considerable modification during migration; they are now, with apparently few exceptions, represented by endemic species. Ten species are figured on plate xxxi.

The characteristic features of an orchid may be illustrated by reference to the flower of *Dipodium punctatum*, which consists of an outer whorl or circle of 3 sepals, somewhat similar in shape and size. They are separate from each other as well as from the more central members, and are therefore called free. Alternate with the sepals are three petals, also free: but the lowest petal is modified in shape, and consists of a large middle-lobe and two much smaller side-lobes. It is thus the most conspicuous feature in the flower, and is known as the labellum. The sepals and petals together are called the perianth. In its centre is the column, a prolongation of the floral axis which bears in a consolidated mass the anther and stigma. The anther, lid-like in shape, is placed on the top of the column, and the stigma is situated just below it. Within the anther are two rounded yellow masses (pollinia or pollen-masses), each grooved on its lower surface. In *Dipodium* and in most epiphytes these masses are generally hard and waxy, but in most

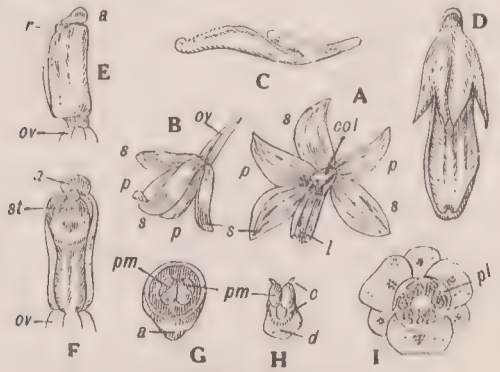
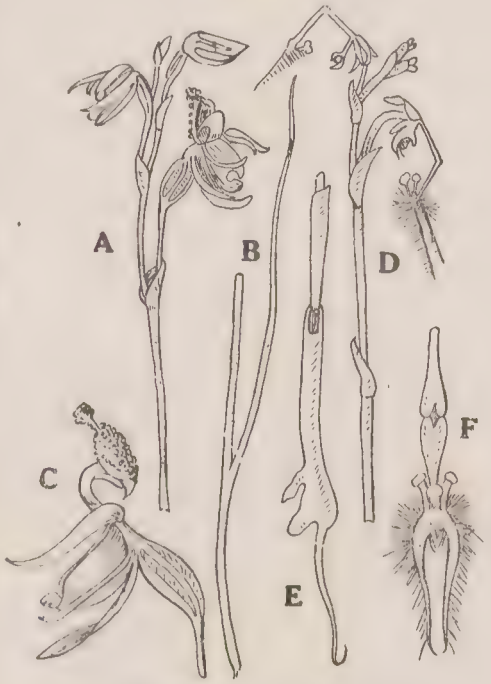
terrestrial forms they are usually soft and mealy. Immediately below the anther, the upper border of the concave stigma is produced into a sterile lobe, the rostellum; this is a small, blunt, glistening projection, which performs important functions in the process of fertilization. The ovary is situated at the base of the flower behind the perianth. It is twisted spirally through an angle of 180°, thus bringing the labellum, which should be normally uppermost, to the lower side of the flower, so as to become a convenient landing stage for insect visitors. In all Australian orchids the ovary contains but a single cell, composed of three large and three small segments; to the former are attached fleshy placentas, which bear clusters of ovules.



Dipodium punctatum.
(A) Flower from front, (s) sepal, (p) petal, (l) labellum, (col) column; (B) side view of flower, (s) sepal, (p) petal, (ov) ovary; (C) labellum from side, showing large middle lobe and one of the shorter lateral lobes; (D) labellum from above, showing its three lobes; (E) column from the side, (a) anther, (r) rostellum; (F) column from front, (a) anther, (st) stigma; (G) anther seen from below, (a) anther-cap, (pm) pollen-masses in situ, each mass is seen to be bilobed; (H) pollinarium, (d) viscid disk, (c) stipes, on to the ends of which the pollen-masses (pm) have fallen from the anther-case; (I) transverse section of the single-celled ovary, (pl) placentae.

The structure of the flower in *Dipodium* is comparatively simple, and represents a plan from which there are many departures; sepals and petals show much variation in shape and colour, and may be free, or adherent to their fellows, or to other segments of the perianth. In *Thelymitra* the third petal is almost exactly similar to the other segments of the perianth. All other genera have a distinct labellum, generally more or less 3-lobed, though the lateral lobes may be small, rudimentary, or obsolete. Its surface may be plain, or furnished with raised lines, excrescences, or calli. Sometimes, as in *Calochilus*, it is densely fringed. Occasionally it assumes fantastic shapes, often resembling living or extinct animals, and frequently insects; such resemblances are noticeable in *Drakaea*, *Spiculoea*, and *Caleana*. Its structure may be further complicated by the presence of spurs, pouches, and appendages of various kinds. These are all probably concerned in the process of pollination, being devices for attracting the attention of insects. The labellum is often strikingly coloured or parti-coloured. In certain Western Australian species of *Caladenia* (*C. lobata* and *C. plicata*) the claw is so flexible and elastic that the slightest breeze gives it a vibratory movement. Movements of a less distinctly vibratory character may also be observed in *Pterostylis barbata* and *P. turfosa*, in both of which the labellum is long, thread-like, and hairy. All such movements tend to attract visitors to the sexual portions of the flower. Occasionally the organ is sensitive and, when stimulated by the touch of a visiting insect, flies up against the column, carrying the insect into the interior of the flower, whence it can only escape by performing some necessary step in the process of pollination. Such imprisonment is effected with surprising rapidity in *Pterostylis*, and some species of *Drakaea*, but more deliberately in *Caleana*.



(A) Inflorescence of *Caleana minor*; (B) stem and leaf; (C) flower. (D) Inflorescence of *Spiculoea Huntiana*; (E) root and stem; (F) labellum.

The column is sometimes extremely short, as in *Diuris*, *Oberonia*, *Zeuxina*; in *Galeola*, *Pterostylis*, and *Caladenia* it is much elongated. The anther is usually inclined forwards in the direction of the stigma. It may be permanently attached to the column, or may (e.g. in epiphytes) fall off as soon as its pollen-contents are liberated. In epiphytes it is lid-like in shape; in terrestrial orchids it exhibits great diversity of form. It is primarily 2-celled, but the cells may be more or less completely subdivided or modified to accommodate the pollinia satisfactorily.

The pollinia vary in number from one to four pairs. In Australian epiphytes, and in some terrestrial genera of exotic origin (such as *Phajus*, *Spathoglottis*, and *Geodorum*), they are waxy in consistence. In the remaining genera, the great majority of which are essentially Australian, the pollen is either mealy or granular. The pollinia sometimes lie free in their cells, quite unconnected with the rostellum, but more usually are connected by their narrow ends with this organ or its representative. Commonly there is a gland on the rostellum to which the pollinia are attached, either directly or by the medium of an elastic strap known as the caudicle. Sometimes there is no gland. The caudicle, when present, is usually single, and is formed by the junction of the elastic strands from the various pollen-

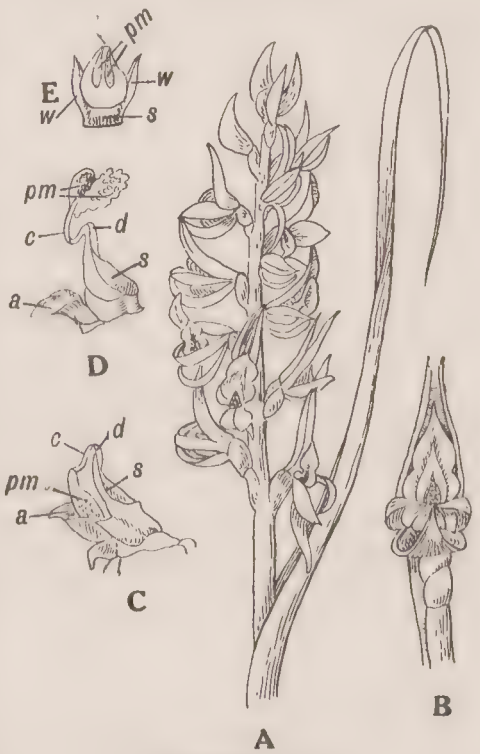
masses. In a few cases, however, it is double; both caudicles may be attached to a common gland, as in *Epipogum*, or each may be inserted into a separate gland, as in *Habenaria*. In *Spathoglottis* there are two caudicles but no gland.

The caudicles mentioned above must be regarded as a product of the pollen-masses, but in the large tribe Vandeae an important modification of the pollinary apparatus takes place. Here there is no true caudicle, this organ being replaced by a single or double linear projection (stipes) derived from the back of the rostellum. This may be seen in *Dipodium*, where a double stipes projects backwards from a glandular disk which has become detached from the rostellum. In the immature flower the pollen-masses occupy their respective cells in the anther, above the stipes, but not in contact with them. If the waxy pollinia are examined at this stage, each will be seen to have a sticky groove on its lower surface. When maturity is reached, each pollen-mass drops accurately on to the stipes below it, and becomes cemented thereto along the line of the groove. The glandular disk, owing to its sticky undersurface, still retains its position lightly on the rostellum, but can easily be removed, together with the stipes and pollinia, by a light touch from an insect visitor. These structures are collectively known as the pollinarium. Within a minute of removal the ends of the stipes, together with the attached pollinia, become depressed, and the latter are then in the exact position necessary for successful pollination of the stigma of the next flower which the insect may visit.

The stigma is situated on the front of the column, almost always just below the anther—though in *Gastrodia* it will be found at the extreme base of the elongated column. In *Pterostylis* it is not sticky, but is usually so in the great majority of Australian orchids. The rostellum, in the mature flower, is apparently always viscid.

In the case of a flower so profoundly modified as the orchid there was much difficulty in tracing the ancestral type from which it has been evolved. We are indebted to the genius of Robert Brown (q.v.) for the elucidation of this intricate problem. As the outcome of a careful investigation into the distribution of certain structures, known as the vascular bundles, together with other considerations, he was led to the conclusion that the flower originally consisted of 3 sepals, 3 petals (one modified to form a labellum), 6 anthers in two whorls, and 3 stigmas, one of which has been specialized to form the rostellum. Of the 6 original anthers, only one (belonging to the outer of the two whorls) is fertile in Australian orchids. In the exotic genus *Cypripedium* this particular stamen is merely a sterile rudiment (staminode); the two fertile stamens belong to the original inner whorl. Many or all of the suppressed stamens may be traced as appendages about the column. In this connection the examination of so-called abnormal flowers—which are often reversions to ancestral type—is particularly instructive; in one such flower, now in the writer's possession, there are five distinct sterile stamens present, in addition to the fertile one, the full complement being thus represented. As a rule, however, stamens which have ceased to be of service in the economy of the plant are completely suppressed, or represented only by mere rudiments, whereas those which may usefully function in another capacity (e.g. the hair-tufts in *Thelymitra*), undergo structural transformation and are retained. With regard to the stigma, evidence of bilobing is present in some Australian orchids, notably in *Pterostylis*, the stigma of which is distinctly bifid. In *Habenaria* there are two separate stigmas, borne on special style-like structures. As pointed out by Brown, the third or sterile stigma is represented by the rostellum.

Three types of mechanism for pollination have been observed in Australian orchids: (1) that suitable for cross-pollination by insects, as in *Dipodium* and *Pterostylis*; (2) that suitable for self-pollination only, as in some species of *Thelymitra*, notably in *T. luteociliata*; and (3) a mechanism suitable for either cross- or self-pollination, so that, in the event of unsuccessful pollination by insects, the plant is able to depend



Prasophyllum gracile.

on its own resources. This occurs in *Prasophyllum gracile*, and probably in many other species of this genus.

In Australian orchids self-pollination is effected much more frequently than was believed probable by Darwin. So far as can be ascertained, no epiphyte is fertilized in this manner, the mode being confined entirely to terrestrial forms. It has been observed in seven or eight species of *Thelymitra*, the best example being *T. luteociliata*. The flowers of this species cannot be said never to open, although they do so very rarely, and then only on excessively hot days; they are, however, fertilized in the bud long before expansion is possible, and long before the full size of the mature flower has been attained. One has, indeed, to search diligently to find a bud young enough to show the condition of the

parts prior to dehiscence of the anther. Other orchids which are known to be self-pollinated are *Spiranthes australis, Orthoceras strictum, Spathoglottis Paulinae,* some species of *Calochilus,* and probably some species of *Diuris.* Other members of the family are still under investigation.

The third method is best studied in *Prasophyllum gracile.* In the immature flower of this species the pollinarium (except the gland) is completely covered by the anther-case. As the flower matures, the anther-point recurves, exposing the caudicle and upper portions of the pollinia to the drying effects of the December air. As a consequence the caudicle begins to curl upwards, dragging the pollinia with it (C). This leaves a triangular space between the caudicle and the back of the rostellum. The pollinarium can now be easily removed by inserting the point of a needle into this space. The back of the gland being sticky, it adheres to the needle, and the pollinia will then be seen to rotate through an arc of 180°. The flowers are much frequented by a small beetle, *Trogoderma adelaidae,* to the head and thorax of which pollinia will sometimes be found adhering. These masses will be observed to present in such a manner that, when the insect visits the base of the labellum in another flower, they are in the correct position to ensure their deposition on the stigma. In a very large number of flowers pollen-masses may be seen adhering to the stigmas, and in many cases the pollinia of the flowers so pollinated are still in situ, showing clearly that the masses on the stigmas have been transported from other flowers. Hence it is certain that cross-pollination does occur in this species in a large percentage of cases. No pollen-carriers were observed other than *Trogoderma.*

Should the pollinarium not be removed, the act of rotation proceeds as follows. It passes through the stage shown in D, and finally the pollinia are deposited, usually with great accuracy, on the middle of the stigmatic surface (E). Occasionally—from accidental circumstances, such as wind, or the irregular curling of the caudicle in the final stage of rotation—there is a tendency for the masses to be deposited elsewhere than on the stigma; but this tendency is usually counteracted by the lateral wings of the column, and pollination is thus successfully accomplished.

However elaborate the mechanism for pollination, a great proportion of Australian orchids depend largely on vegetative reproduction. In certain genera, such as *Caladenia, Microtis, Prasophyllum,* and *Thelymitra,* capsules are produced freely, and the minute seeds are shed in countless millions. Some doubtless survive and germinate, but a vast proportion must perish.

Prasophyllum gracile first came under the writer's observation in 1907, when he received from a correspondent two specimens only. Though carefully looked for, no more specimens were discovered until December 1912, when they were found blooming in vast numbers in a much-frequented part of the mountains that had been swept by an extensive fire in the earlier part of the year. It was assumed that they would reappear in the same locality; but, although a thorough search has been made annually not a trace of them has yet been found. And yet in this orchid infinite precautions have been taken to ensure pollination. It has been observed that during seasons following extensive bush-fires the mountains become carpeted with orchids, many belonging to species that are comparatively rare at other times. It might reasonably be supposed that fierce conflagrations would

* Genera peculiar to Australia.

destroy any dormant seeds, but it seems that, on the contrary, the fires create conditions favourable for germination. Possibly germination has in some way been stimulated by the chemical products of the burnt forests, but the more probable explanation is to be found in the presence of a benign fungus. Modern research has shown that many (possibly all) orchids are dependent for germination on the presence of such a fungus, which has been found associated with their roots or tubers. In fact, long before such an association was known or understood, horticulturists had discovered that it was possible to cultivate the seed of certain exotic species by growing it in close proximity to the roots of the parent plant. It is possible that these great forest conflagrations create conditions favourable to the propagation of the fungus most suitable for the abundant production of our terrestrial orchids.

In some genera seed-capsules are produced with comparative infrequency. Few orchids, for example, possess such a highly specialized mechanism for pollination as *Pterostylis*, yet very few capsules are produced by many members of that genus, the mode of reproduction being chiefly by the vegetative method. It is conceivable that a set of conditions may arise unfavourable to such a mode of propagation but favourable to reproduction by seed, so that the mechanism of pollination would be of real practical utility to the plant. In any circumstances a few capsules seem to be produced every season, and these probably contain sufficient seed to ensure the perpetuation of the species, even if the conditions should be so rigid as to result in the failure of the vegetative method.

The genera most largely represented in Australia are *Dendrobium*, *Bulbophyllum*, and *Sarcochilus* among the epiphytes; *Thelymitra*, *Diuris*, *Prasophyllum*, *Microtis*, *Pterostylis*, and *Caladenia* among terrestrial forms. Many species are sufficiently beautiful or interesting to repay cultivation, e.g. *Sarcochilus Fitzgeraldi* and most species of *Dendrobium*. Among ground orchids such showy genera as *Phajus*, *Calanthe*, *Spathoglottis*, and others are well worthy of the horticulturist's attention. R.S.R.

Ord, Sir Harry St. George (1819-1885), son of Captain H. C. Ord of the royal artillery, was born at North Cray in Kent on 17 June 1819, educated at Woolwich, and appointed to the royal engineers in 1837 (2nd lieutenant 1837; lieutenant, 1839; captain, 1846; brevet-major, 1854; lieutenant-colonel, 1859; brevet-colonel, 1864; major-general, 1869). His early service was mainly in the West Indies (1840-5) and West Africa (1849-50). During the Crimean war he was attached to a joint Anglo-French expedition operating in the Baltic, and won his brevet majority at the siege of Bomarsund. In November 1855 he was seconded for work under the colonial office, partly on the Gold Coast (1855-6) and partly at the Hague and Paris in connection with negotiations concerning the Dutch and French West African colonies. Thenceforward he administered a chain of colonies, beginning with Dominica (1857-61), and proceeding through Bermuda (1861-6) and Singapore (1867-73) to Western Australia (1877-80)—see Governors. While at Bermuda he was for a short time employed on special work on the Gold Coast, and his term at Singapore was prolonged by special desire beyond the ordinary limits. During his term in Western Australia, Perth was connected by telegraph with Adelaide (1877). Retiring on 6 April 1880, he returned to England, and died on 20 August 1885. (C.B., 1865; Kt. Bach., 1867; K.C.M.G., 1877; G.C.M.G., 1881.)

J.S.B.

Orioles, perching birds belonging to the family Oriolidae, members of which are found throughout the warmer parts of the eastern hemisphere; the orioles of America belong to a distinct family (Icteridae). Two species of oriole occur in Australia—the Green Oriole

Green Oriole (*length* 11½ *in.*).

(*Oriolus sagittatus*), found in the eastern and northern parts of the continent, and the Yellow Oriole (*O. flavocinctus*), confined to the north.

Orioles frequent forest country, and live principally on bush fruits, but also devour insects. Their notes are varied and melodious, and they are capable mimics, imitating the songs and calls of other birds. Their nests are neat cup-shaped structures suspended from the forks of horizontal or drooping boughs. The eggs are from two to four in number, white, with dots and blotches of various shades of brown.

W.B.A.

Orites, a genus of the family Proteaceae, endemic in south-eastern Australia. The flowers are small, in pairs within each bract, on short spikes; corolla-segments dilated at the tips, short and concave; anthers perfect, enclosed in the concave segments; fruit a leathery follicle; seeds compressed, with a terminal oblique wing. *O. excelsa* (Prickly Ash of the Dorrigo district in New South Wales; also known as 'silky oak'), is a large tree of up to 100-120 feet, with timber so much resembling that of the true silky oak (q.v.) as to become a frequent substitute for it. Sawyers object to this timber, as it contains a mineral substance that dulls the saws.

Ormond, Francis (1829-1889), son of a merchant captain who settled at Port Phillip in 1842, was born at Aberdeen in Scotland on 23 November 1829, educated in Liverpool, and brought by his parents to Geelong, where he at first tried commercial life and then became a squatter. This occupation brought him great wealth, which he determined to spend on the encouragement of education in Victoria. Among his gifts and legacies for this purpose the principal were a sum of over £100,000 to Ormond College within the university, £20,000 to endow the chair of music at the university, and £11,000 to the Melbourne Working Men's College. His will further provided large sums for hospitals and asylums at Melbourne, Geelong, and Ballarat. He died in France, during a visit to Europe, on 5 May 1889. From 1882 till his death he was a member of the Victorian legislative council.

Ornithorhynchus. See Monotremes and Platypus.

Orthoptera, an order of insects comprising cockroaches, earwigs, mantises, stick-insects, crickets, locusts, and grasshoppers. Some of these families are in many respects highly specialized, others are the most primitive of existing winged insects; the order, indeed, might be defined as including all insects in which the mouth-parts are of a very primitive mandibulate type, the hind-wing is provided with an anal fan, and the larvae are not aquatic. The fore-wing, when present, is fairly hard and tegminal; the anal area of the hind-wing is expanded into a large anal fan, which can be folded up; cerci are present; the metamorphosis is slight, the young and adult forms showing no great differences, and the wings developing gradually through a number of instars.

Handlirsch's extensive splitting-up of this order, which has been followed in recent years by many authors, is based primarily upon a misconception as to the nature of the wing-venation, and cannot be justified. The families here given may be legitimately considered super-families, and many have been extensively subdivided. The old division into two sub-orders, Cursoria and Saltatoria, is adopted here also; the latter division is a natural one, whereas the former conveniently contains all the more archaic types. To these will be added, as a very specialized side-branch, the sub-order Dermaptera (earwigs). In Cursoria are included cockroaches, mantises, stick- and leaf-insects, in which the hind-legs are not formed for jumping and the anal fan of the hind-wing folds up only lengthwise. Saltatoria include the closely related crickets, locusts, and grasshoppers, in all of which the hind-legs are specialized for jumping. All these are discussed elsewhere under their own names. R.J.T.

Orton, ARTHUR (1834-1898), born at Wapping, London, on 20 March 1834, was the youngest son of a shipping butcher, who sent him to sea at the age of 14 in a vessel bound for Chile. The boy deserted at Valparaiso, and lived for some months with a Chilean family named Castro. In 1851 he returned to England, in 1852 migrated to Tasmania, and settled in 1864, after a more or less adventurous career, at Wagga in New South Wales, where he traded as a butcher under the name of Thomas Castro. There in 1865 a neighbour from Hampshire showed him an advertisement asking for news of Roger Charles Doughty Tichborne, heir to the estates of a Roman Catholic Hampshire family. This Roger, who was born in 1829 and educated at Stonyhurst, held for three years a commission in the 6th dragoon guards, but sold out in 1852 and went off to South America; he was last heard of in 1854, when he embarked at Rio de Janeiro in the ship *Bella*. The finding of wreckage from this ship was taken as conclusive evidence that she had foundered, and in 1855 Roger Tichborne's younger brother succeeded to the family estates. His mother, however, maintained the belief that Roger was still alive, and repeatedly advertised in British and colonial newspapers for news of him.

It was one of these advertisements that was shown to Castro-Orton, and he was gambler enough to see in it a chance of wealth. He had for some time entertained friends in Wagga with stories of a mysterious past too high for a butcher; it was notorious that he had lived in South America; and the vague description in the advertisement fitted him moderately well, except that Roger Tichborne had been slim and Orton was excessively stout (a few years later he scaled 24 stone). When, therefore, on being shown the advertisement he solemnly buried his face in his hands and refused to discuss it, the news went round Wagga, and a local solicitor, William Gibbes, jumped to the conclusion that the true Roger had been found; this belief was all the more acceptable because Orton's monetary affairs were in confusion and he had been staving off creditors with the assurance that he was expecting money from England. Urged on by Gibbes, Orton wrote to Lady Tichborne asking for money enough to pay his passage home —at this stage he seems merely to have hoped that the funds so procured would allow him to join an Orton brother who was farming in California. But public excitement over the romantic story took the ordering of affairs out of his hands. Arriving in Sydney on his way overseas, he found local 'society' waiting with open arms to receive Sir Roger Tichborne, and local bankers eager to supply him with funds; any lingering doubts of his identity were dispelled when Bogle, an old West Indian servant of the Tichborne family, professed to recognize him. From him, from his Hampshire neighbour in Wagga, and from other sources, Orton gained a great deal of information about the Tichbornes, which he used familiarly and with great effect. Funds being now available, he did not wait for the remittances from England, but took ship for Panama—ostensibly *en route* to London, actually hoping to get away to California. His fellow-passengers, however, made it impossible for him to go elsewhere than to London without exposing the fraud. So to London he went, arriving there on 25 December 1866, and thence to Paris to meet his 'mother' —who immediately recognized him, despite the fact that he had grown so stout, spoke vulgar English, and could not understand a word of French (which was almost Roger's native tongue). She handed over to him all Roger's papers and family letters, and allowed him £1000 a year. On his return to England he set himself to find out details of the Tichborne home, visited the neighbouring villages, and there told stories that left most of the villagers without a doubt as to his identity; he also took into his personal service a man from the 6th dragoons, who made him familiar with the regimental jokes and stories. Consequently a number of prominent persons, delighted to have their memories refreshed with stories of the long-ago, welcomed 'Sir Roger' home again.

The Tichborne estates, however, remained in the possession of the younger brother until his death, and then were held in trust for his infant son, for none of the Tichbornes except the dowager admitted the newcomer to the family circle. Lady Tichborne died in April 1868, and Orton, soon finding himself penniless, on 11 May 1871 brought a civil action for the recovery of 'his estates;' to finance him, £40,000 was raised by the issue of Tichborne bonds to the public. Meanwhile the trustees of the estate had learned that on the evening of his arrival in London he had visited Wapping and inquired after the Orton family, and that members of the family had received money from him. Moreover, his handwriting and appalling spelling agreed very well with the handwriting and spelling of letters written by Arthur Orton to an old sweetheart in Wapping. The trustees, therefore, not only denied that he was Roger, but maintained that he was Orton. The action dragged on over many months (from 11 May 1871 to 5 March 1872, the actual trial occupying

102 days), owing to the necessity of taking evidence in South America and Australia: Orton was at last nonsuited, and chief justice Bovill immediately had him arrested for perjury. During his trial, which opened on 22 April 1873, the British treasury in response to public pressure —at least half England being convinced that Orton was Roger—defrayed the expenses of his witnesses. On 28 February 1874 he was sentenced to 14 years' penal servitude, and his counsel, Dr. Kenealy, was severely castigated by the chief justice. On 19 October 1884 Orton was liberated, an act of parliament having meanwhile declared Roger Tichborne to be dead, and having conferred on the actual holders of the estates power to deal with them as they wished. On 9 April 1895 Arthur Orton published in *The People*, a London newspaper, a full confession of his guilt. On 1 April 1898 he died.

Orton, Joseph (1795-1842), born at Hull in England on 1 October 1795, is first heard of as a Wesleyan missionary in Jamaica, where he was imprisoned for six months in 1826 for preaching to slaves after sunset. Returning to England, he took up work in the Bury St. Edmunds circuit, and in 1831 migrated to Sydney, where four years of his wise administration reestablished the mission. After a visit to New Zealand, he established Methodism in West Maitland and Bathurst; on 18 May 1834, with the help of George Allen, he established the Sunday School Society. On 24 February 1836 he left Sydney for Hobart to superintend the newly formed district there, and in April visited Port Phillip, where on the 24th he preached to aborigines and settlers, William Buckley (q.v.) acting as his interpreter. It was on his recommendation that Gipps granted 64,000 acres at Buntingdale for an aboriginal reserve. On 2 March 1842 he sailed in the *James* for England and died while rounding Cape Horn in April. His manuscript journals give interesting details of his journeys, his services to the Church and to convicts, and his public movements.

J.C.

O'Shanassy, Sir John (1818-1883), born in county Tipperary in 1818, migrated to Australia in July 1839, reached Melbourne on 15 November, was persuaded by Father Geoghegan (q.v.) to stay there rather than go on to Sydney, and bought a small station near Western Port; but, lacking capital and confronted by scab in his flock, he abandoned the run, opened a draper's shop in Melbourne in 1846 and soon (mainly by his wife's energy) established a thriving business, which during the gold-rush of the early fifties became the source of a substantial fortune. In Melbourne he was from the first involved in local politics. He helped to found the anti-transportation league, ardently advocated the separation of Port Phillip from New South Wales, and when this was achieved became on 11 September 1851 one of the three elected representatives of Melbourne in the new legislative council. Here he practically led the opposition, attacking the nominee element with vigour and urging the early grant of fully responsible government. Sir Charles Hotham, recognizing his ability and sincerity, placed him on commissions to enquire into the state of the goldfields (after the Eureka Stockade business, q.v.), to report on the proposed constitution (1853), and to investigate the state of the crown lands (1855). When the colony obtained self-government in 1856, O'Shanassy was elected to the assembly by both Melbourne and Kilmore, and chose the latter. Again he led the official opposition—this time in co-operation with C. G. Duffy (q.v.)—and in March 1857 defeated the Haines ministry and formed one of his own; this, however, was but a scratch team, and lasted about six weeks. Haines, returning, held office for slightly over ten months; then O'Shanassy with a strengthened team came back for nearly 20 months. The two next ministries used up two years in fruitless attempts at land legislation that should encourage agriculture at the expense of pastoral settlement. On 14 November 1861 O'Shanassy for a third time took office, with an experienced team that might almost be called a coalition, and passed a crown lands act (usually known by the name of its deviser, Duffy) and a local government act that did good work for another ten years. Defeated in June 1863, and succeeded by one of the strongest ministries that have ruled Victoria, he never saw office again; he remained in the assembly until 1866, then visited Europe and was knighted by Pope Pius IX for his services (which were great) to Roman Catholics in Australia; returning in 1868, he was elected to the council, but resigned in 1874; finally he secured election to the assembly in 1877 as member for Belfast, and on his rejection by that constituency in 1883 took to his bed and died on 7 May of that year.

Till the end of his premierships O'Shanassy was regarded as an advanced liberal and an enemy of the squatter interest, but he never loved universal suffrage or vote by ballot. In later years his conservative temperament mastered him, mainly because the new liberalism was identified with protection, state education, and other measures to which his religion or his habit of mind opposed him. From first to last he warmly supported any movement that tended towards increased immigration or Australian federation—in the latter connection he joined Duffy's committee of 1857, which brought South Australia and Tasmania into harmony but was thwarted in its federal desires by the coldness of New South Wales. From first to last his political work was marked by great parliamentary capacity, and entirely untainted by any suspicion of self-seeking. (C.M.G., 1870; K.C.M.G., 1874.)

Osmiridium. This alloy of osmium and iridium, usually found in small particles associated with an ore of platinum, exists in separate deposits at several places on the west coast of Tasmania. These have been worked steadily (except for an interval in the early days of the war) since 1911; in that year 271 oz., valued at £1188, were won, but in 1923 (the last available official figures) the yield was 673 oz., valued at £19,642. The record yield was in 1920, when over 2000 oz. were obtained; in October the price was £42 per oz. The work is unorganized, and is carried on by prospectors. In 1925 a new field was opened up on the Adams River, which in a few months produced £74,000 worth of metal and at the end of November was yielding £1000 worth a day. In 1926 there were over 500 miners at Adamsfield, and the conditions were much the same as in the diggings Bret Harte described; revolvers were worn, and a vigilance committee had been appointed.

Osmiridium is used chiefly for hardening platinum jewellery and the points of gold pens, for making watch-bearings, and—since increased production has reduced the price—for pointing drills for special work. See Mineralogy.

Osprey. See Hawks.

O'Sullivan, EDWARD WILLIAM (1846-1910), born at Launceston in Tasmania on 17 March 1846, and educated principally by his mother, was at an early age apprenticed to the printing trade on the Hobart *Mercury*. After a visit to Sydney in 1869-71 he established in Hobart the *Tasmanian Tribune*; after two years he sold out, and in 1874 established in Melbourne another *Tribune*, an evening newspaper run on co-operative lines, which was unsuccessful. For four years he was editor of the *St. Arnaud Mercury*, then returned to Melbourne to join the *Argus*, and in 1882 left the *Argus* for the Sydney *Daily Telegraph*. A year later he found that press work interfered with his political interests; in Victoria he had supported Graham Berry, and in New South Wales adopted even more advanced views. He was a strong advocate of the 8-hour movement, early closing, protection, arbitration, courts of conciliation, and woman suffrage. In 1882 and 1885 he stood for parliament without success. In 1885 elections were not all held on the same date, and on the night of his defeat (for South Sydney) he took train for Queanbeyan, where he had at the moment no supporters and no organization; in seven days he had won the seat against four others, to hold it for 19 years. In 1904 he won the Belmore electorate in Sydney, and retained the seat till his death.

In 1896 O'Sullivan was chairman of the first parliamentary committee on old-age pensions, and in 1899 took office under Sir William Lyne as secretary for public works; he retained this post under John See (1901-4), and in 1902-3 seized the opportunity that made him memorable. In 1902 a severe drought depressed New South Wales; O'Sullivan, foreseeing a recovery, and knowing that a bold public works policy would relieve the immediate depression and justify itself in more prosperous years, induced the treasurer to borrow heavily for railway extensions and similarly productive works. In 1895-9 New South Wales had appropriated about 13½ millions for public works, in 1905-9 the amount was about 10½ millions; in 1900-4 O'Sullivan used nearly 18 millions. At the time he was violently denounced for unprecedented recklessness, but his policy justified itself by its results, and his expenditure has in recent years been many times exceeded—in 1920-4, for instance, the state's loan expenditure reached 51½ millions. In the short-lived (June-August 1904) Waddell ministry O'Sullivan was minister for lands; after that time he sat in opposition until his death, which took place at Sydney on 25 April 1910.

In the late nineties O'Sullivan had returned to his old pursuit of journalism, editing for three years (1897-9) the *Freeman's Journal*. He was a voluminous writer of articles and pamphlets, and in 1906 published in Sydney *Under the Southern Cross*, a collection of articles, stories, and speeches. But his real value to Australia lay in his gift of imagination and prescience; since Macquarie's time no other man has so nearly equalled that great governor in foreseeing and providing for future expansion.

Ovens, JOHN (1788-1825), born in Ireland and educated for the Church in Dublin, changed his mind and entered the army in 1808 (ensign, 1808; lieutenant, 1810; captain, 1819; major, 1824). The next year his regiment (the 73rd) was despatched with its colonel, Lachlan Macquarie (q.v.), to New South Wales; on arrival Ovens was promoted lieutenant and made engineer and artillery officer for the colony, an appointment which seems to have involved the superintendence of public works in general. At the end of 1811 he obtained leave of absence, returned to England, joined the 2nd battalion of his regiment, and (finding it was not on the roster for war service) exchanged into the 74th; this regiment was serving in the Peninsula under Brisbane, who was one of the brigadiers of Picton's 3rd division, and Ovens seems to have come almost at once under Brisbane's direct notice. He was severely wounded at Vitoria, but recovered in time to be present at Orthes and Toulouse, though the effects of the wound lasted many years. During the last years of the war he was probably on Brisbane's staff, and Brisbane, when in 1821 he was given the governorship of New South Wales, invited Ovens to go with him as aide-de-camp, and soon after they reached Sydney made him chief engineer. We hear no more of him until in May-June 1823 he accompanied Captain Currie on a tour past Lake George to the upper Murrumbidgee and the edge of the Monaro district; this is usually spoken of as the 'discovery' of the Murrumbidgee, but R. H. Cambage has made it clear that Throsby reached that river in 1821. In 1824 Ovens's long service had its reward. Brisbane obtained for him his brevet majority, made him his private secretary—a proceeding which greatly annoyed the official secretary, Frederick Goulburn—and commended him to Bathurst 'under the solemn impression that no public officer here has rendered me the same essential service, the Colony such general benefit, or imposed upon the Mother Country such a heavy debt of gratitude.' But the load grew too heavy, and on 7 December 1825 he died. He was buried on Garden Island, in a plot already occupied by the coffin of Ellis Bent (q.v.), and when that cemetery was evacuated the two bodies were reinterred under a single tombstone at St. Thomas's cemetery in North Sydney.

Ovens's name was given by Hume and Hovell to the first stream they reached after crossing the Hume-Murray; they thoughtfully held the balance even by naming the next stream the Goulburn. Another John Ovens almost immediately appeared in New South Wales: this officer, a lieutenant in the 57th regiment, must not be confused with Major Ovens of the 74th. See EXPLORATION BY LAND.

Overlanding. See PASTORAL INDUSTRY.

Overland Telegraph-line, THE. There are now several telegraph-lines in Australia that might claim this name; but the first so called, and the one best known by the name, stretches from Port Augusta at the head of Spencer Gulf in South Australia to Port Darwin in the Northern Territory—approximately 1800 miles—and links the Commonwealth with Asia and Europe by a connecting cable to Banjuwangi in Java.

Up to 1872 the mail-service between Australia and Europe was carried on once a month by the Peninsular and Oriental Navigation Company, heavily subsidized by the colonial governments. The lack of a more speedy means of communication with Europe was a great restraint on business, and negotiations were therefore initiated by Queensland, and by South Australia (which then controlled the Northern Territory) with the British-Australian Telegraph Company; in the end the South Australian proposals were accepted, and in June 1870 the company made an

agreement with the government of the day to lay a cable from Java—which was already connected with Europe—on condition that a land line was constructed from Port Augusta to Port Darwin. The whole line, by land and sea, was to be open for use on 1 January 1872. At this time the South Australian population was little over 180,000; but they cheerfully accepted the task of constructing what was then estimated at 1500 miles of telegraph-line through a country which had up till then been only once traversed from south to north—by John McDouall Stuart (see EXPLORATION BY LAND). The ultimate cost was over £300,000.

The only hills worthy of mention on the route chosen for the line are the Macdonnell Ranges, and a pass was known through them. It was decided that the construction of the line should be divided into three sections, No. 1 proceeding due north from Port Augusta, and No. 3 from Port Darwin due south; No. 2, through the ranges, was looked on as the most difficult.

The supervision of the line was entrusted to Charles Todd (q.v.), postmaster-general and superintendent of telegraphs, an Englishman who had been appointed in 1855 to establish a telegraph system in the colony. Section No. 1 was constructed by Edward Meade Bagot under contract, and was completed in 15 months; the central section, undertaken by the government, was also finished within little more than the estimated time, although in both these sections immense difficulties were caused by lack of water and suitable timber, the absence of roads, and the great distances over which material and stores had to be hauled. Section 3, which was let to an Adelaide firm, was unexpectedly found to be the most troublesome owing to the swampy nature of the country, the annual rainfall in that part of the Northern Territory being about 70 inches. No time was lost in starting. The contractors planted the first pole at Port Darwin on 15 September 1870, but progress was so slow that the government official in charge of the section found it necessary to terminate the contract. An engineer with a party of 80 men was sent up on 27 July 1871 from Adelaide, but the flooded country baffled him also; and it was not until Todd, with another large party, came to his aid, after the difficulty had been vainly attacked from the Roper River, that a route was found which, owing to the partial drying of the swamps, admitted of slow but steady progress.

On 22 May 1872 Todd sent the first message from Port Darwin to Adelaide, but—as part of the third section was still incomplete—it had to be conveyed by horsemen for considerable distances, and did not reach the capital until 20 June. On 22 August the line was completed and the first through message from Port Darwin was received. The cable company, however, had its own difficulties, and before the land line was completed the cable from Java was interrupted, so that the first through message from London did not reach Adelaide until 22 October. On the 30th Todd returned to Adelaide and reported that he had inspected the line for the entire distance from Port Darwin to Adelaide, and that it was constructed in a substantial manner, but required iron poles in many places where timber was liable to destruction by white ants or bush-fires. The line has since been entirely repoled with iron poles.

The line took 23 months to build. Some 36,000 telegraph-poles, weighing 5000 tons, were used, some being carted to a distance of 350 miles; a large number of iron poles were hauled from 400 to 500 miles, and over 200 tons of other materials were carried into the interior. Several thousand sheep and cattle were driven an average of 500 miles to supply the constructors with food; the scrub timber had to be cut, grubbed, and cleared for an average width of 50 feet over some 500 miles; large quantities of building-stone, sand, etc. for the permanent stations had to be carted inland, and a receiving station of 22 rooms for the cable and land lines was erected at Port Darwin. The other telegraph-stations, which are about 200 miles apart, were completed some time afterwards. Fortunately, the natives along the route gave very little trouble, and not a single white man was killed during construction. See PACIFIC CABLE.

E.W.G.

Owen, SIR WILLIAM (1834-1912), born on 4 November 1834 and educated at Cheltenham and at Trinity College, Dublin, was called to the Irish bar in 1859 and, migrating to Sydney the next year, was at once admitted to that of New South Wales. Devoting himself to his profession (with the exception of a very short period of work in the public service in 1865), he became a Q.C. in 1882, and in October 1887 was made chief judge in equity, transferring to the common law side in 1896. In 1892 he was a member of the commission which investigated charges brought by a member of parliament against the chief commissioner for railways. In 1905 he was given sole charge of the investigation into scandals connected with the administration of crown lands, and afterwards was made head of a tribunal which cancelled many wrongly obtained leases, and whose decisions, when questioned, were expressly validated by act of parliament. In 1908 he retired from the bench into private life, and died on 22 November 1912. (Kt.Bach., 1906.)

Owenia, a genus of the family Meliaceae, consisting of trees with sprays of small flowers and succulent fruits; the stem and branches usually contain a milky juice. The five species indigenous to Australia are endemic. *O. acidula* (Native Peach, or Nectarine, but better known by its aboriginal names 'gruie' and 'colane') is an inland species, confined to New South Wales and Queensland; it is considered one of the handsomest trees on the western plains, and is a valuable stand-by for stock in time of drought. The sub-acid fruits, which will relieve thirst, and are eaten by both aborigines and settlers, are of a crimson colour and the size of a small nectarine. The stones are made into bracelets and other ornaments. *O. cepiodora* (Onion-wood) is a medium-sized tree confined to the coastal brush forests of northern New South Wales and Queensland; its popular name is derived from the smell of the wood, which, however, soon disappears after cutting. *O. cerasifera* is the Queensland Plum; its red juicy fruit is very acid when fresh, but if buried in sand for a day or two is very refreshing. *O. venosa* (Sour Plum), also a Queensland species, produces a large acid fruit. That of *O. acidula* (Emu-apple) is eaten by natives in northern Queensland.

Owlet. See FROGMOUTHS AND NIGHTJARS.

Owls, nocturnal birds with powerful hooked beaks and sharp claws, belonging to the order Strigiformes. Two families are represented in Australia, each by five species. The brown owls (Strigidae) include the largest Australian

species, the Powerful Owl (*Ninox strenua*), a somewhat rare inhabitant of forest country along the eastern coast, whose nocturnal cry is said to resemble the bellowing of an ox; and the well-known smaller Boobook Owl (*Ninox boobook*), whose cry is one of the most familiar sounds in the bush at night-time. Nowadays the call is generally represented by the words 'more-pork' or 'mopoke,' and it is commonly (but erroneously) supposed that the sound is made by the frogmouth (q.v.), on which the name 'mopoke' has been conferred in consequence.

The barn owls (Tytonidae) include the beautiful pale buff or whitish Delicate Owl (*Tyto alba*)—identical with the English barn owl, white owl, or screech owl—and the similar but larger Masked Owl (*Tyto novae-hollandiae*), peculiar to Australia.

Boobook Owl (*length* 16 *in.*).

In Australia, as in other countries, owls are commonly classed with hawks, dingoes, foxes, etc., and regarded as noxious; yet they are beyond question among the most valuable birds, since they keep down the numbers of rodents and of the larger nocturnal insects. Owing to the fact that owls bring up the harder portions of their food, and eject them from the mouth in pellets, it is possible by collecting the pellets from beneath the birds' roosting-places to study their feeding habits without destroying them. A long series of observations, made by Captain S. A. White of Adelaide on a pair of delicate owls inhabiting his grounds, proved that they fed almost entirely on mice, rats, and insects, sometimes also obtaining starlings and sparrows. An examination of numerous pellets of the boobook owl indicates that this species feeds almost entirely on insects, but occasionally captures mice and small birds. W.B.A.

Oxley, JOHN (1781-1828), born in Yorkshire in 1781, entered the navy as a lad and reached Australia in H.M.S. *Buffalo* in 1802 as acting-lieutenant (he had served his full time for the rank, but until 1806 had no opportunity of passing the necessary examination). In 1804 he helped Robbins to survey Western Port, and on 18 March 1805 was given his commission as lieutenant without examination; he then commanded the *Buffalo* (November 1805) and *Estramina* (April 1806). In 1807 he returned to England in the *Buffalo*, coming back in November 1808 in the transport *Speke* to become 1st lieutenant in the *Porpoise*. In that ship he again returned to England in 1810, but on the recommendation of Matthew Flinders was in July 1811 appointed surveyor-general of New South Wales, and reached Sydney on 1 January 1812. He was already a landowner in the colony, having been granted 600 acres at Kirkham near Camden in 1808, and 1000 more by Paterson in 1809; the Paterson grant was at first disallowed by Macquarie, but was confirmed in 1815. Macquarie employed him very actively beyond the Blue Mountains, where in 1815 he planned the town of Bathurst and in 1817-18 made important explorations that are described under EXPLORATION BY LAND. In 1823 he was sent north along the coast to look for a new penal settlement site (see EXPLORATION BY SEA) and in the course of his voyage discovered the Brisbane River. In June 1825 he commenced a survey of the settled districts of the colony into counties and parishes, and was still engaged on this work when he died at Kirkham on 26 May 1828.

Apart from his work as surveyor-general, Oxley did the colony good service in many ways. Macquarie found him a valuable if sometimes obstinate adviser, and it was mainly his doing that, after 1821, grants to new settlers had to be properly surveyed before they were handed over. His politics were 'exclusive,' and he opposed trial by jury. In 1823 he was made a member of the legislative council, but was left out of it when Darling arrived. As an official he disliked private explorations and did his best to block the Hume-Hovell expedition of 1824; he also objected to the settlement of Western Port in 1826 and to other attempts made by Darling to anticipate a supposed French project of annexation. Darling described him as 'a clever man but too little controlled;' he added, however, that Oxley was 'a philanthropist almost in the extreme, often led by injudicious zeal, but indefatigable, conscientious, and honourable in the highest degree.' In 1822 he published in London his *Narrative of Two Expeditions into the Interior of New South Wales* (London, 1820); Barron Field's *Geographical Memoirs on New South Wales* (London, 1825) contains his report on one of his expeditions. J.V.C.-B.

Oxylobium, a genus of the family Leguminosae, endemic in Australia, consisting of shrubs with (chiefly) yellow flowers, many of them highly ornamental. *O. parviflorum* is the Box Poison-plant, and *O. retusum* the Bloom Poison-bush—a name also given to a *Gastrolobium* (q.v.); *O. lineare* and *O. capitatum*, also regarded as poison-bushes, are confined to Western Australia; *O. trilobatum* (Native Holly), is an ornamental shrub with holly-like leaves and showy flowers; *O. scandens* is a pretty climber.

Oyster-catchers. See WADERS.

Oysters and Oyster-culture. The Australian coast is plenteously endowed with oysters, of which two species are of commercial importance, namely, the Rock Oyster (*Ostrea cucullata*) and the Mud Oyster (*O. angasi*). The

mud oyster, although very much larger than the rock oyster, is of comparatively little value commercially, as it is of inferior flavour and its keeping qualities are poor. It occurs in marketable quantities only on the southern coast, the principal fishery being at Port Lincoln in South Australia; in the early days of settlement, however, immense quantities were found in New South Wales as far north as Port Jackson. The term 'mud' oyster is in reality a misnomer; it does not live in the mud, but is found on a firm bottom, in rock-crevices or actually attached to rocks, below low-tide mark. It is nowhere cultivated, attempts to do so having proved unsuccessful. Like the English oyster, it is hermaphrodite, and the eggs are fertilized in the mantle cavity, considerable development taking place before they are ejected into the water.

The rock oyster, which flourishes from mean high-water mark to depths of 50 feet or more, occurs round the whole coast of Australia, with the exception of the southern seaboard. The maximum degree of development is attained on the east coast between the Tropic of Capricorn and 38° S. lat. Outside Australia it is found in India, Japan, and northern New Zealand. Its keeping qualities are excellent, its flavour probably unsurpassed. The sexes are distinct; the sperms and ova are liberated direct into the water, where fertilization takes place. The time of spawning varies, but is generally expected in late summer.

The cultivation of the rock oyster forms an extensive industry, particularly on the coast of New South Wales. The culture-grounds are situated in inlets and estuaries where the salt water extends inland for many miles. Cultivation is practised either on the foreshores and mud-flats between high and low water, or below low-water mark. In the latter case immature oysters are dumped from punts on a firm level bottom, and when fully grown are gathered with dredges, or occasionally by divers. Grounds suitable for this type of cultivation are now limited, on account of the destruction caused by the mud-worm (for which see lower down).

For cultivation above low-water mark four principal methods are employed, the oysters being grown on (*a*) stone slabs (usually sandstone) stuck upright in the mud or laid on a bed of poles; (*b*) sticks, placed either singly or in bundles; (*c*) maturing-beds, either formed naturally by a firm and level bottom, or built up of mud and dead shells and drained by channels; (*d*) wire-netting stretched over frames and supported on posts clear of the mud (see plate xxxii). Of these (*a*) and (*b*) are by far the most extensively used in New South Wales, and, whereas stone has the advantage of permanence, the stick method gains in ease of transportation. The sticks used are obtained principally from the Black Mangrove (*Aegiceras majus*), which grows on the banks of many rivers; Swamp Oak (*Casuarina glauca*) and White Honeysuckle (*Banksia integrifolia*) are used to a less extent. These trees are chosen because they resist the attacks of 'cobra' (ship-worm) long enough to allow the oysters to mature—a process which usually takes about three years. Bundles of sticks are laid out to catch spat on grounds where oysters attach in abundance; when the shells are sufficiently strong (at from 6 to 12 months) they are transported on punts to fattening-grounds, where growth is much more rapid. Here the sticks are thrust into the mud singly and upright, from one to two feet apart. Speaking generally, breeding-grounds are found near the mouths of estuaries, and fattening-grounds are situated higher up, where the water is brackish. Methods (*c*) and (*d*) are used exclusively for developing immature oysters, which are scattered over the surface and left to mature. Both types are commonly adopted in New South Wales and Queensland.

The chief pests are the Mud-worm (*Polydora ciliata*), boring whelks, several species of fish, and a turbellarian worm known as the Wafer (*Leptoplana australis*). In certain rivers floods occasionally do much damage. The mud-worm is by far the worst enemy, and not only takes toll of great quantities of oysters, but in many localities renders otherwise valuable ground useless for culture-purposes. It crawls into the shell when the oyster is feeding, and gathers a deposit of mud over which the oyster is forced to build a layer of nacre. Continued invasions weaken the oyster, and eventually kill it. Most damage is done in muddy localities near low-tide mark, and in deep water. The whelks comprise several species, which by means of their rasp-like tongue (radula) bore small round holes in the shells of young oysters, and then devour the flesh. The fish pests are mullet (*Mugil* spp.) which consume the eggs and free-swimming larvae, stingrays, porcupine- and toad-fishes, and the Black Bream (*Sparus australis*).

Rock oysters are marketed in 3-bushel bags, the great majority being carried by steamer from the rivers of New South Wales to Sydney, whence large quantities are transhipped to Melbourne, Adelaide, and Fremantle. Queensland also exports to the other states, but, owing to the ravages of the worm, the supply from this source is much less than formerly. Upwards of £140,000 worth of oysters are produced in Australia annually; of this amount New South Wales in 1925 contributed £92,774 and Queensland £32,548. During 1925 Victoria imported 10,234 bags of rock oysters (valued at £40,936) from New South Wales and Queensland—chiefly the former—and 1784 bags, principally of mud oysters (valued at £2676), from New Zealand, besides marketing a certain amount grown locally. In the Melbourne market the mud oyster brings from one-third to one-half the price of the rock oyster.

No oysters are canned in Australia. Oyster-bearing grounds are let by the government at rentals ranging from 5s. to £5 per annum per hundred yards of foreshore (or per acre of off-shore leases) according to productiveness.

See T. C. Roughley's *Oyster Culture on the George's River, New South Wales* (Sydney, 1922) and *The Story of the Oyster* (1925). T.C.R.

P

Pacific Cable, The. Up to the end of 1902 telegraphic communication between Australia and England was carried on over lines that traversed foreign countries and cables that at many places lay beneath alien waters. As far back as 1879 the inconvenience of this arrangement had been pointed out by Sandford Fleming, chief engineer of the Canadian government railways, who suggested that advantage might be taken of the extension to the Pacific coast of the Canadian Pacific Railway (and its telegraph-lines) to link up the British colonies in the western Pacific by a submarine cable. The proposal was discussed at the colonial conference of 1887 (see Imperial Conferences). The Ottawa conference of 1894 resolved that Britain should be asked to survey a route, Canada and the Australasian colonies sharing the expense. In 1896 a Pacific Cable Committee under the chairmanship of Lord Selborne reported in favour of the scheme, and in 1901 an Imperial act authorized the construction of a cable from Vancouver Island to New Zealand and to Queensland. The work was completed in October 1902, and the cable opened for use on 7 December.

During the preliminary discussions it was decided that ownership of the cable should be vested in the governments concerned, their shares being allotted as follows:—out of 18 shares in all, five to Britain, five to Canada, and two each to New South Wales, Victoria, Queensland, and New Zealand. After federation the Commonwealth government took over the obligations of the three Australian States, and thus owns six shares. The act of 1901 created a managing board of eight members, three representatives of Britain, two of Canada, two of Australia, and one of New Zealand. Management is centralized in London, though a 'manager in the Pacific,' stationed at Sydney, is responsible for the working of the cables and cable-stations and the conduct of business in Australasia.

The first cable was laid from Bamfield on Vancouver Island to Fanning Island (3458 nautical miles), thence to Suva in Fiji (2043 miles), thence to Norfolk Island (982), and thence to Southport in Queensland (837)—a total length of 7320 miles. A branch ran from Norfolk Island to Doubtless Bay in New Zealand (519 miles). In 1912 the land lines from Doubtless Bay to Auckland were replaced by cables (199), and an alternative route was also provided between Auckland and Sydney (1251); and in 1923 Southport was connected with Sydney (510) and Auckland with Fiji direct (1255). The Bamfield-Fanning Island and Fanning Island-Fiji sections are in process of duplication; the new cables, which have twice the working capacity of those first laid, will be ready for use in October 1926. The stretch from Bamfield to Fanning Island is the longest in the world covered by one cable. Yet neither on this stretch nor on that from Fanning Island to Suva has there been any interruption to traffic in 23 years, except when in 1914 the German cruiser *Nürnberg* cut the cables at Fanning Island as an act of war. This immunity from natural harm is mainly due to the depth at which the cable lies (often over 3000 fathoms), and to the singularly even character of the ocean-bed.

The capital cost of the original enterprise was about £2,000,000, which was provided by the British government at 3 per cent, to be repaid in 50 annual instalments of £77,545. It was further provided that a sum of £39,150 should be set aside annually for repairs and renewals. The finances of the cable were thus burdened from the first with fixed payments amounting to nearly £117,000 a year, and consequently no profits were shown until 1916. The annual deficits—which were borne by the governments in proportion to their shares—decreased from £87,000 odd in 1903-4 to less than £8000 in 1914-15, and from 1916 onwards the profits have been devoted either to strengthening the repair and renewal fund or to reducing the capital debt. On 31 March 1925 this debt amounted to £1,306,665, whereas the reserve and renewal fund had to its credit £2,279,826, after meeting the cost of all the additional cables.

The increase in traffic is illustrated in the following table:—

Year.	Words—Ordinary.	Government.	Press.	Special.	Total.
1902–3	202,313	24,210	1,831	...	228,354
1907–8	1,041,433	105,519	84,940	...	1,231,892
1912–3	1,288,949	193,688	717,942	460,228	2,660,807
1917–8	2,186,917	2,443,299	361,328	2,461,174	7,452,718
1922–3	3,813,294	476,122	1,056,963	4,641,224	9,987,603
1924–5	3,481,708	418,877	1,058,345	6,930,470	11,889,400

Incidentally it may be noted that the increase was not so steady as this table may imply. It was steady up to 1914-15; during the next year it doubled (from four to eight million words), mainly because of a great expansion in the special-rate ('deferred' and 'week-end') messages; in the period 1917-20, though special-rate and press messages fell away, there was a huge increase in government messages, probably due to the peace negotiations; since 1921 the increase has again become steady. The sudden increase in special-rate messages in 1924-5 is accounted for by the institution in September 1923 of 'daily letter telegrams' transmitted at a reduced rate after the ordinary messages are dealt with.

Padbury, Walter (1820-1907), born at Stonestill in Oxfordshire in 1820, migrated with

his parents to Swan River in February 1830, and owing to the death of his father a few months afterwards, had to make his own way in life. At the age of 16 he became a shepherd, and as time went on seized the opportunity of taking up pastoral pursuits, which he followed throughout his life, being interested at the same time in many commercial ventures. In 1874-6, and again in 1885, he was president of the Royal Agricultural Society of Western Australia, and sat for five years as a member of the old legislative council before the introduction of responsible government. Dying on 18 April 1907, he bequeathed large sums to various church and charitable institutions—the largest being to the government homes for old men and women, which benefited to the extent of over £30,000.

Palaeontology. The general factors governing distribution and the evolution of faunas are mostly of a cosmopolitan type, modified only by the major changes in the distribution of land and oceanic spaces which are dealt with under GEOLOGY (q.v.). The Palaeozoic fauna of Australia is cosmopolitan, no definitely Australian fauna being recorded until the Permo-Carboniferous age.

CAMBRIAN.—Fossiliferous limestones and shales of this age occur in Western Australia, South Australia, Queensland, the Northern Territory, Victoria, and Tasmania. *Olenellus* beds with *Salterella* occur in the Kimberley district of Western Australia. On Yorke Peninsula in South Australia Archaeocyathinae limestones are well developed, as well as beds containing *Micromitra, Kutorgina, Obolella, Nisusia, Eoorthis, Hucnolla, Stenotheca, Ophileta, Salterella, Hyolithes, Dolichometopus, Conocephalites, Olenellus, Microdiscus,* and *Ptychoparia.* At Beltana occurs the most important horizon of Archaeocyathinae so far discovered; eight genera and 32 species have already been described. From Ekeldra in the Northern Territory, *Agnostus, Paradoxides, Microdiscus* and *Ptychoparia* have been recorded. In Victoria (north-eastern Gippsland, near Mount Wellington) occur limestones with *Plectorthis, Lingulella, Scenella, Agnostus, Ptychoparia,* and *Crepicephalus.* The Heathcotian beds containing *Dinesus* and *Notasaphus* may be either Cambrian or Cambro-Ordovician. In Tasmania Archaeocyathinae occur, and in the north quartzites yielding *Dikelocephalus* and *Concephalites.* Cambrian beds with *Ptychoparia,* etc., occur near Mount Isa in northern Queensland.

ORDOVICIAN.—Horizons of Lower Ordovician age which occur in Victoria and South Australia form a remarkable example of the world-distribution of a type of pelagic organisms, the graptolites. Typical developments range from Cambro-Ordovician to Upper Ordovician, and the fauna of the various horizons have more than a general similarity to those of beds of corresponding age in Europe and America. The older beds occur in southern areas; the Upper series extends into central-western New South Wales from Cooma to Peak Hill and as far north as Tallong near Marulan. The graptolite-bearing series of slates and altered rocks are subdivided as follows:—

Upper Ordovician—Gippsland and N.S.W.
Lower Ordovician—Darriwillian
Castlemanian
Bendigonian
Lancefieldian

The Upper Ordovician beds are characterized by the abundance of *Diplograptus, Climacograptus, Didymograptus,* and *Leptograptus.* The Darriwillian may in its faunal aspect be regarded as a series of passage-beds between Upper and Lower Ordovician. The underlying Castlemanian contains a preponderance of *Didymograptus,* in the Bendigonian *Phyllograptus, Tetragraptus* and *Bryograptus* are typical, and at Lancefield *Bryograptus* and *Dictyonema. Phyllograpti* of many species are typical in all the Lower divisions.

In central Australia Ordovician limestones contain *Endoceras, Orthoceras, Asaphus* spp., *Ctenodonta, Raphistoma,* and *Ophileta.* In Tasmania the Gordon River limestones with *Cyrtodonta, Ctenodonta, Tellinomya, Bellerophon, Helicotoma, Hormotoma, Raphistoma* may prove to be of Silurian age. Ordovician brachiopods and trilobites are also found in the valley of the Florentine River.

SILURIAN.—This series occurs entirely in the eastern States, and is of a cosmopolitan type; the fossiliferous limestones and shales of New South Wales and Victoria may be in part correlated with the Wenlock and Ludlow beds. There is an abundant molluscan, brachiopod, trilobite, and coelenterate fauna, the main characteristics being the great variety of *Halysites* (in New South Wales), *Tryplasma, Spongophyllum,* and *Rhizophyllum,* and the presence of endemic rugosa such as *Mucophyllum, Mictocystis, Arachnophyllum, Vepresiphyllum,* etc. *Conchidium* and *Barrandella* horizons are well developed in New South Wales.

DEVONIAN.—These strata occur in Western Australia, Victoria, New South Wales, and Queensland. In Western Australia the Kimberley, Napier Range, and Gascoyne River beds contain a Lower or Middle Devonian fauna—stromatoporoids, *Cyathophyllum, Phillipsastrea,* tabulate corals, and *Atrypa reticularis*; but some fossils recorded from these beds belong to adjacent Permo-Carboniferous areas. In Gippsland (Victoria) Middle Devonian limestones with *Spirifera yassensis* and *Receptaculites* are well developed. Freshwater Upper Devonian or Lower Carboniferous beds contain *Archaeopteris, Sphenopteris,* and *Cordaites*; these beds also occur in southern New South Wales. In New South Wales the Lower Devonians, which are well developed in the Murrumbidgee district, are characterized by a great development of *Receptaculites,* one species attaining a diameter of at least a foot. Tabulate corals are abundant. The typical fossils are species of *Actinocystis, Diphyphyllum,* and *Spirifera yassensis.* The Middle Devonian, developed in the western districts, contain varieties of *Spirifera cristata* and pterinoid bivalves, etc.

The Upper Devonian sediments of New South Wales are of two types; the arenaceous of the western districts, containing *Rhynchonella pleurodon, Spirifera disjuncta,* and *Lepidodendron australe,* and that of the New England district, composed of coralline and radiolarian limestones, claystones, and cherts. The limestones contain such corals as *Favosites, Heliolites, Sanidophyllum, Spongophyllum, Diphyphyllum,* and *Syringopora*—all species distinct from the Silurian and possessing little in common with the Lower Devonian series. The limestones and cherts comprise a great development of interbedded radiolarian rocks near Tamworth. The upper mudstones contain *Lepidodendron australe* in abundance. In Queensland the Fanning River and Burdekin limestones are coralline, and con-

tain abundance of *Alveolites, Araeopora, Campophyllum, Stringocephalus, Atrypa,* etc.

CARBONIFEROUS.—Beds of this age occur in New South Wales, Victoria, and Queensland. The Mansfield beds of Victoria (regarded as Lower Carboniferous) contain *Lepidodendron australe* and fish—*Gyracanthides, Acanthodes, Strepsodus, Elonichthys,* etc. These beds may prove to be in part Upper Devonian. In New South Wales marine and freshwater Carboniferous beds occur. The marine fauna is of the Mountain Limestone type, and consists mostly of cosmopolitan types of brachiopoda, *Productus semireticulatus, Schizophoria resupinata, Leptaena analoga, Spirifera striata, Phillipsia, Griffithides,* and *Brachymetopus.* The coral fauna is typical—*Zaphrentis, Cyathophyllum, Lithostrotion, Aphrophyllum, Michelinia,* etc. *Mesoblastus* and *Tricoelocrinus* occur in Queensland. The freshwater beds have a Middle Carboniferous facies, with *Anthracomites ovata, Cardiopteris, Pitys,* and *Lepidodendron veltheimianum.* In Queensland the Star beds, well developed round Rockhampton, have a fauna very similar to that of the New South Wales series. Doubtful Carboniferous beds containing *Lepidodendron* occur in Western Australia. In eastern Australia no Carboniferous species extend into the overlying Permo-Carboniferous, and there is usually a well-marked unconformity between the two systems. The closing phase of the Carboniferous in New South Wales is represented by the Kuttung series of freshwater glacial beds—tillites and varve rocks. Glacial conditions also continued in the succeeding Lower Marine series of the Permo-Carboniferous.

PERMO-CARBONIFEROUS.—Of the Australian palaeozoic faunas that which attracts most attention is the marine Permo-Carboniferous. The interest is due to the change which continued a glacial phase in existence (Kuttung) when sedimentation was beginning, and to the effect of land-barriers as hindering migration between the eastern and western Permo-Carboniferous shores. The eastern Permo-Carboniferous fauna exhibits the typical Australian facies, and contains the development of many purely Australian types. The two main divisions of the marine sediments—the Lower and Upper Marine series (separated in typical localities by a freshwater Phase—the Greta coal-measures) vary little in character in New South Wales, Queensland, and Tasmania.

The principal elements of the fauna are:—

Foraminifera.—*Nubecularia, Pelosina, Hyperammina, Haplophragmium, Lituola, Endothyra, Lagena, Nodosaria, Geinitzina,* etc. *Nubecularia* is in great abundance, and the arenaceous and sub-arenaceous types preponderate. Horizons occur in both Lower and Upper Marines; in association with the Pokolbin (Lower Marine) horizon Wollong (Upper Marine) horizon are glacial beds, indicating the cooling of the water.

Spongida.—Sponges are rare; the anchoring spicules of *Hyalostelia, Lasiocladia,* and certain burrowing sponges (*Clionolithus*) are found in the Lower and Upper Marines of New South Wales.

Coelenterata.—One of the noticeable features of the Permo-Carboniferous of eastern Australia is the impoverished Coelenterata fauna, due without doubt to glacial conditions at the initiation of sedimentation. A few species of zaphrentoid corals, close to Hinde's genus *Plerophyllum,* show an extravagant development of stereoplasma. The tabulate *Trachypora* forms a well-marked zone-fossil in the Upper Marines.

Echinodermata.—This phyllum is of particular interest. Blastoids are represented by *Tricoelocrinus,* and the Crinoidea by the giant *Phialocrinus princeps* of the Upper Marines, 4½ inches in diameter. *Tribrachiocrinus* (a dicyclic form with large radianal and 'X' plate, three double brachia and two single) is peculiar to eastern Australia. A large *Archaeocidaris* and several species of palasterids (*Etheridgeaster, Monaster,* and *Palaeaester*) occur in the Lower Marines—one (*Etheridgeaster giganteus*) has a span of 7 inches.

Bryozoa.—The great development of the trepostomatous *Stenopora* is a characteristic of this period in eastern Australia. The massive *S. crinita* forms irregular polyzoaria of from 1 to 2 feet in size. Dendroid and flabellate types are also common, and present many species as yet undescribed. The Fenestellidae are also well developed. *Fenestella* is rare, but such types as *Phyllopora, Polypora,* and *Protoretepora* are extremely abundant, and in some cases form distinct limestones in the Lower Marines. Fenestellidae are equally developed in the Lower and Upper Marines, and in all provinces.

Brachiopoda.—This may be regarded as a *Martiniopsis* fauna. This protean genus is extremely abundant in all suitable sediments. Associated with it are winged Spiriferae, all strongly ridged, *Spiriferina, Dielasma, Chonetes, Productus, Strophalosia, Aulosteges, Lingula,* and *Orbicula.* In Queensland, in the Bowen beds, we find also *Derbyia seuilis.* It must be noted, in contradistinction to the Permo-Carboniferous brachiopod fauna of Western Australia and the Northern Territory, that Carboniferous species are entirely absent, also the Orthidae and *Leptaena* group, *Athyris, Cyrtina, Syringothyris,* and *Reticularia.*

Pelecypoda.—In this group of Mollusca what may be termed the Pacific facies of the Australian Permo-Carboniferous asserts itself, with purely endemic genera such as *Cleobis, Maeonia, Astartila, Pachydomus, Notomya, Aphanaia, Merismopteria, Clarkia, Deltopecten*—a giant form, a transition between *Aviculopecten* and *Pecten*—and *Stutchburia,* an edentulous variant of *Pleurophorus. Chaenonomya* of the Nebraska-Permian is very characteristic of certain estuarine deposits. The most interesting type is *Eurydesma,* mainly characteristic of the Lower Marines, noteworthy for its absence from Western Australia and its presence in the olive shales of the Himalayas and the Marine Karoo of German West Africa. The fauna is noteworthy for the preponderance of edentulous gaping types.. Cosmopolitan genera, such as *Nuculana, Scaldia, Solecurtus, Aviculopecten, Solenopsis, Modiolopsis* also occur. The fauna is evenly distributed along the east coast.

Gasteropoda.—There is nothing distinctive in the eastern gasteropod fauna, which includes *Platyschisma, Straparollus,* and various pleurotomarioids—*Keeneia, Ptychomphalina, Mourlonia,* and a naticoid type, together with a patelloid genus and *Orthonychia.*

Pteropoda and Conularidae.—*Hyolithes* is common, and a giant *Conularia,* reaching a length of 20 inches, occurs in the eastern provinces.

Cephalopoda are uncommon, but *Orthoceras* and *Agathiceras* (*Goniatites*) are abundant in the Ravensfield sandstone of New South Wales.

Crustacea.—*Leaia* and *Estheria* occur in the Newcastle coal-measures.

In Western Australia it has been customary to class certain formations as Carboniferous and certain as Permo-Carboniferous; but there is good reason to believe that the entire series, developed in the Irwin, Gascoyne, Mingenew, Minilya, Lyons River, and Kimberley districts is more properly Permo-Carboniferous as regards the mingling of the faunas.

One of the prominent features of the eastern Permo-Carboniferous fauna is the absolute absence of any Carboniferous species, whereas in the west (besides Indian species and local varieties) there are Carboniferous types such as *Schizophoria resupinata, Rhipidomella, Productus semireticulatus, Leptaena analoga, Phillipsia,* etc. These forms in eastern Australia are confined to the Star beds of Queensland and New South Wales, beds separated from the Permo-Carboniferous of that region by a well-marked unconformity. A most remarkable horizon of sandstones containing *Gastrioceras* is well developed in the Gascoyne area. Taking into consideration

the fact that the so-called Permo-Carboniferous sedimentation of both eastern and western Australia was initiated by glacial stages which must be regarded as synchronous, this mingling of faunas in Western Australia points to a direct communication with the Permo-Carboniferous coast-line of the Himalayan and Salt Range region. The fact that certain Producti, Pectinidae, Terebratulidae, and Spiriferidae of the West have a close resemblance to eastern Australian types may, perhaps, be regarded as betokening parallel development, rather than of specific identity. The Permo-Carboniferous of the Northern Territory has western affinities.

As regards the flora of the Permo-Carboniferous, a Lower Gondwana flora is preserved in both western and eastern Australia. The earlier beds are characterized by gangamopteroid types, the upper by *Glossopteris* and more especially by *Phyllotheca*.

MESOZOIC.—These rocks, freshwater and marine, range from Trias to Cretaceous. In all the States the freshwater beds are of Trias and Jurassic age. There is good reason to regard the so-called Jurassic (Ipswich) system as being the freshwater series directly succeeded by the marine Cretaceous. In Western Australia freshwater beds of Jurassic age occur at Mingenew with *Otozamites* and *Plagiophyllum*; at Champion Bay *Belemnites, Dorsetensia, Stephanoceras, Trigonia,* etc., occur; at the Greenough River are oolites yielding *Alectryonia marshii, Ctenostreon pectiniformis, Radula duplicata, Trigonia,* etc. It is possible that the Gingin chalk is of Cretaceous age. The fauna of the marine Mesozoic of Western Australia exhibit marked affinities with European and Asiatic species. At Point Charles in the Northern Territory, there is evidence of an abundant Cretaceous fauna—*Aucella, Scaphites, Histrichoceras,* etc., dwarfed forms with (in almost every case) Gault affinities.

Almost as marked as the difference between the eastern and western Permo-Carboniferous fauna is the lack of community between the marine Mesozoic fauna of the east and that of the west. Stratigraphical evidence indicates a continuity of sedimentation from, at latest, Jurassic to the end of Cretaceous time, and this has led to an apparent mingling of faunas. The Cretaceous Mediterranean—which occupied portions of Queensland, New South Wales, and South Australia—is characterized by numerous species peculiar to the region and many endemic genera among the Mollusca. The most typical forms are *Maccoyella, Pseudavicula,* and *Fissilunula,* all endemic types occurring in both Lower and Upper Cretaceous. The cephalopodan fauna is not large, but is noteworthy for the great size of the *Crioceras* and *Ancyloceras* group. *Ichthyosaurus, Plesiosaurus,* and *Cimoliosaurus* are represented by several species. The barrier which prevented the mingling of the eastern and western Permo-Carboniferous faunas seems to have persisted into late Mesozoic time.

The Mesozoic flora of eastern Australia may be divided into three groups—(1) the Ipswich-Walloon flora of Queensland, the Clarence basin of New South Wales, the South Gippsland basin of Victoria, and the Lake Eyre basin of South Australia; (2) that of the Tasmanian upper coal-measures; (3) the Hawkesbury series west of Sydney. The Ipswich beds show the cosmopolitan Trias-Jurassic vegetation with *Cladophebis denticulata,* various species of *Thinnfeldia, Taeniopteris daintreei, Podozamites, Baiera,* etc. They occupy the lower portion of the great artesian basin, and are succeeded conformably by marine Cretaceous shales and sandstones. The rather scanty evidence at present available indicates that the sagging of the Mediterranean region was associated in its early stages with lacustrine conditions, leading up to an invasion of the sea and marine sedimentation. These conditions on the coastal district ceased at the close of freshwater sedimentation, except in the Maryborough district of Queensland, where both freshwater and marine sedimentation took place. An abundant insect fauna, described by Tillyard from the Wianamatta and Ipswich series, contains many new species of Coleoptera, Hemiptera, Homoptera, and Orthoptera, associated in the Wianamatta shales with an isopod crustacean, *Phreatoicus.*

The upper coal-measures of Tasmania may be correlated with the Gippsland measures of Jurassic age. *Taeniopteris daintreei* is wanting, but *Cladophebis denticulata* is abundant, with *Thinnfeldia, Phyllotheca,* etc.

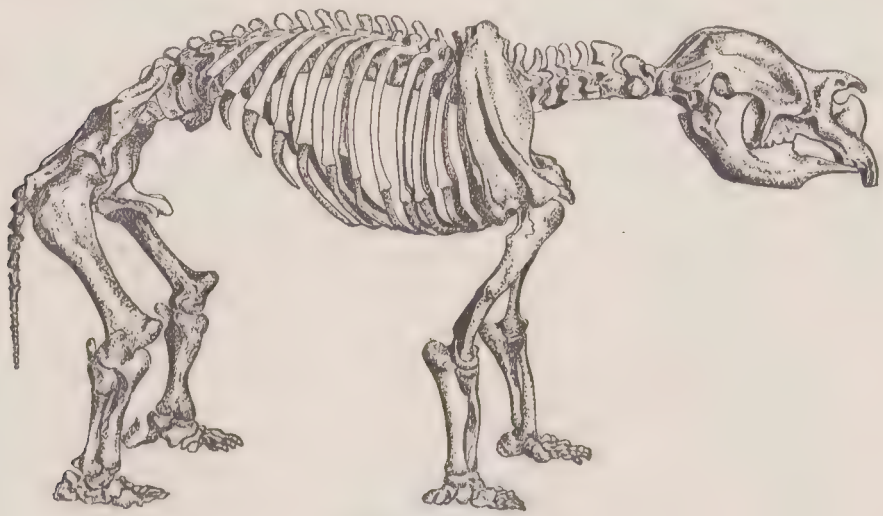
The Hawkesbury series is made up of the Narrabeen, Hawkesbury, and Wianamatta stages. The Narrabeen shales directly succeed the upper coal-measures (Permo-Carboniferous) with no break in sedimentation, and there is a mingling of the *Glossopteris* and Lower Mesozoic flora—*Glossopteris* (plate xxxiii, fig. 2) and *Schizoneura.* The Narrabeen, Hawkesbury, and Wianamatta stages have a well-developed flora with *Thinnfeldia odontopteroides* (in several varieties), *Macrotaenopteris, Alethopteris,* conifers, and *Phyllotheca*; the differences from the Ipswich flora are possibly due to more arid conditions. The Hawkesbury sandstones and Wianamatta shales have a well-developed fish-fauna (*Cleithrolepis, Gosfordia, Semionotus, Dictyopyge, Belonorhynchus,* etc.), together with labyrinthodonts—*Platyceps, Bothriceps* (shown on plate xxxiii, fig. 1), *Mastodonsaurus*—in part of Palaeozoic and of Rhaetic affinities. A depauperate foraminiferal horizon occurs in the Wianamatta shales. It is usual to regard these beds as in part of Triassic age, possibly slightly older than the Ipswich. At Talbragar in New South Wales beds with *Taeniopteris daintreei* (plate xxxiv, fig. 4), *Podozamites, Palissya,* and *Alethopteris,* contain a distinctive fish-fauna—*Leptolepis, Coccolepis, Aphnelepis,* etc.

CAINOZOIC.—The marine fauna is remarkable for the great development of sediments, and for the intense variation, ranging from Balcombian to Pleistocene and characterized by faunal characters dependent on changing water-temperature and bathymetric conditions. The Balcombian series affords evidence in many cases of a fairly deep water-deposition; the overlying Janjukian is a shallower series, characterized by foraminiferal limestones of an Upper Miocene type. *Turritella* limestones are well developed in South Australia, and at Table Cape—where the oldest Australian marsupial (*Wynyardia bassiana*) is found. The newer Kalimnan and Werrikooian series show in their molluscan content an approach to the Pleistocene, which in Australia is distinguished by its terrestrial and lacustrine deposits and by its fauna and flora.

TERTIARY.—Terrestrial beds containing plant-remains are found in several States; the oldest series occurs in the deep leads, which may date back to late Eocene or early Miocene time. The vegetation of these deposits in eastern Australia bears considerable resemblance to that of the modern 'brushes,' and affords evidence of more humid conditions. In late Tertiary and Pleistocene time the inland plains supported a giant

marsupial fauna—*Diprotodon, Nototherium,* members of the Phascolomidae, *Thylacoleo,* Macropodidae, and monotremes such as *Proechidna* and *Ornithorhynchus* together with ratite birds (*Dromornis, Genyornis,* etc.), reptiles, and chelonia—*Megalania, Crocodilus, Meiolania,* etc. The giant members of this fauna have been found in all the States, but are most abundant in the great central plains of Queensland, New South Wales, and South Australia, where their remains occur in old lake-basins, mud-springs, and river-beds. Their destruction was due to a great diminution of rainfall which took place in late Pleistocene time.

In 1926 about four hundredweight of fossil bones were found in Jurassic (Lower Walloon) deposits on Durham Downs station near Roma in Queensland; they comprised caudal vertebrae, fragments of long bones from a hind-limb, and shattered portions of the pelvic girdle. From these H. A. Longman reconstituted a giant herbivorous dinosaur, *Rhoetosaurus brownei* (Rhoetus was a mythological Greek giant, and Durham Downs is owned by A. J. Browne). The anterior caudal vertebrae of this monster are 18 inches high, about 6 inches long, and weigh 30 lb. each; the fragment of the femur-shaft is 28 inches round, and the complete bone



Diprotodon australis.

must have been over 5 feet long; the tail—of which 16 consecutive vertebrae are preserved—tapers rapidly, and the manner in which adjoining vertebrae are connected presents features not apparent in other dinosaurs. The enlarged neural canal ('tail-brain') is well marked. *Rhoetosaurus* belongs to the family Camarasauridae in the sauropod group of herbivorous dinosaurs; its length was probably 40 feet. The bones are in the Queensland Museum. W.S.D.

Fossil Marsupials.—The fossil remains of mammals hitherto discovered in Australia do not carry the history of this group very far back in geological time. Whereas in Europe and America remains of mammals—chiefly jaws and teeth of small, long-extinct monotremes, marsupials, and insectivores—are found in deposits of Jurassic and even Triassic and Cretaceous age, in Australia no such remains have been discovered in coeval deposits. The earliest Australian fossil mammal, *Wynyardia,* was found in Tertiary strata. It belongs to none of the recognized marsupial groups, and probably represents a generalized group which flourished in Tasmania before the diprotodont and polyprotodont types became differentiated.

To the much later Pleistocene belongs an abundant marsupial and monotreme fauna, remains of which have been found in river and lake deposits in all the States, more especially on the inland plains. This fauna comprises specimens nearly related to existing forms, others of extinct types, and many much larger than any at present in existence. Among these is *Diprotodon,* which appears to have been intermediate in structure between the phalangers and the kangaroos, and was as large as a rhinoceros. *Nototherium,* another extinct form of large size, seems to connect *Diprotodon* with the wombats on the one hand and the phalangers on the other. *Thylacoleo carnifex* (Pouched Lion) is the only representative of the family Thylacoleontidae. The living animal was about as large as a leopard, and—though its habits are still under discussion—was almost certainly carnivorous, feeding on the herbivorous marsupials of its time; many tooth-marked bones of such marsupials have been found in association with *Thylacoleo* remains. The complete skull of a large specimen is 10 inches long and more than 8 inches wide. The dentition consists mainly of a large canine-like incisor and an elongated and specialized pre-molar on each side of both jaws; the pre-molars (carnassials) have a sharp oblique cutting-edge, and those of the upper jaw are about 2 inches from front to back. The other teeth are mostly small, and were apparently of little use (see plate xxxiv, fig. 1). Isolated teeth were figured in Sir Thomas Mitchell's *Three Expeditions into the Interior of Eastern Australia* from specimens found by him in the Wellington caves; the fossil was subsequently named by Richard Owen from additional material. Its nearest relatives belong to the Phalangeridae, so that *Thylacoleo* represents a formerly herbivorous marsupial which acquired carnivorous habits and a special-

ized dentition. This Pleistocene fauna also included members of existing genera, some of huge size, others not larger than their congeners of the present day. The recent discovery of *Nototherium* in Tasmania indicates that during the Pleistocene period Tasmania had not yet lost, or had temporarily re-established, land-connection with the mainland.

On the mainland, but not in Tasmania, remains of the dingo are found alongside *Diprotodon* and other extinct marsupials; the advent, therefore, of this non-marsupial mammal must have taken place at a very early period—perhaps even before the earliest human beings found their way into the Australian region.

Recent discoveries.—Besides the dinosaur mentioned above, Australian fossil beds have recently yielded a new reptile and a distinctly bizarre marsupial, a member of the *Nototherium* group known as *Euryzygoma dunense*. The genus was established by H. A. Longman in 1921 from a skull found at a depth of 70 feet in a well at Brigalow on the Darling Downs. The skull is more than 2 feet long and, owing to the extraordinary development of the cheek-bones (inferolateral processes of the zygomata), 2 ft. 2 in. wide. *Euryzygoma* shows affinities with *Phascolarctus* (koala), *Phascolomys* (wombats), and *Macropus* (kangaroos), but is evidently a very specialized type; it was at least as big as a bullock, and its molar teeth demonstrate its herbivorous habits. The extraordinary cheek-processes were probably associated with cheek-pouches such as are found to-day on a small scale in wombats and koalas.

The reptile *Kronosaurus queenslandicus*, was found in Cretaceous deposits at Hughenden in Queensland, and described in 1924 by H. A. Longman from a fragment of a lower jaw containing the remains of six teeth. It is allied to the giant pliosaurs of Europe, which have a relatively large head and a short neck; its paddle-shaped limbs show that it was a powerful swimmer. As its teeth were nearly 10 inches in length and 1½ inches in maximum diameter, it was probably one of the giants of the Pliosauridae.

W.A.H.

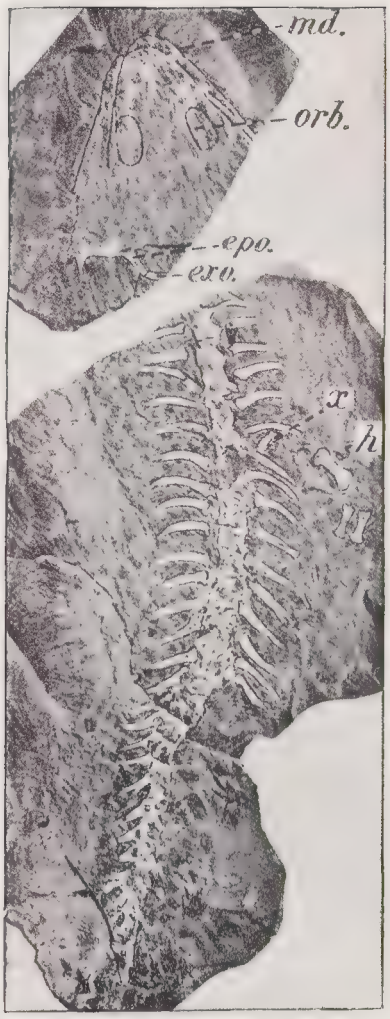
Fossil Insects.—The record of the class Insecta, as preserved in its fossils, comprises winged forms (Pterygota) only. The wingless forms (Apterygota), comprising the orders Thysanura (silverfish, bristle-tails) and Collembola (spring-tails), are assuredly the most ancient of existing insects, but these delicate creatures have left no fossil record, and we do not know at what geological epoch they first appeared upon the earth. As the skeleton of an insect is almost entirely external, and composed of a non-cellular substance (chitin) which is very resistant to acids and alkalies but dissolves slowly in water, it is seldom that the actual substance of the skeleton is preserved. Usually the chitin is changed through chemical action, or is completely dissolved away, leaving only an impression of the insect on the rock within which it has become enclosed. Further, most insect-fossils consist of wings alone; the chitin of these is harder and more resistant than that of the body, and is not exposed to decay from the proximity of the internal organs.

The earliest-known fossil insects are found in the Upper Carboniferous of North America. They consist entirely of Palaeodictyoptera, an order of large insects whose wings show not only the ordinary main veins, but also a more or less dense meshwork of irregular venation between them. At a somewhat later horizon in the Upper Carboniferous, at Commentry in France, the Blattoidea (cockroaches) form about 94 per cent of the insect fauna. In the Lower Permian of the northern hemisphere the Palaeodictyoptera have disappeared, but the cockroaches continue dominant; thenceforward the percentage of cockroaches declines rapidly, until in Tertiary strata they number less than one per cent of the total. All the fossil insects described from Palaeozoic strata in the northern hemisphere are Hemimetabola—they have not succeeded in developing a true resting (pupal) stage. Between the Permian and the Lias there is a great gap; the Lias shows insects much more like those of the present day, with 59 per cent of Holometabola (insects with a true pupal stage) and only 41 of Hemimetabola. In Tertiary strata Holometabola account for 81 per cent of the total, and at the present day for 87 per cent.

Belmont and Ipswich Beds.—Two Australian beds fill the gap between the Permian and the Lias—those of Belmont and Newcastle in New South Wales, which lie close to the top of the Permian, and the Ipswich beds in Queensland, which lie in the Upper Trias. Only ten specimens have so far been obtained from the former; the latter have yielded more than 200 specimens already, and promise to become one of the most important fossil insect-beds yet discovered.

Insects from the Belmont and Newcastle beds have been found either in the *Glossopteris* shales, just above the 'dirty seam' in the cliffs at Newcastle, or at a somewhat higher horizon in a cherty shale uncovered in a small quarry near Belmont. They consist only of Psocoptera, Homoptera, Mecoptera, and an allied order Paramecoptera. Homoptera are represented by the genera *Permoscarta* and *Permofulgor*, both of them allied to present-day Cercopidae and Jassidae, but not referable with certainty to any given family. The peculiar genus *Lophioneura* is probably ancestral to the present-day Psocoptera. The scorpion-flies (Mecoptera) are represented by the fore- and hind-wings of a fine choristid genus, *Permochorista mitchelli*. Closely allied to this is the genus *Mesochorista* from the Trias of Ipswich; and the direct descendants of these fossil forms are still extant, showing little change, in the genus *Taeniochorista* and its allies of the present day. The finest discovery at Belmont is the fossil *Belmontia mitchelli*. This has been placed in a new order, Paramecoptera, and is undoubtedly an ancient form collaterally related to the true scorpion-flies, and directly ancestral to the Trichoptera and Lepidoptera. All the above fossils were discovered by John Mitchell of the Newcastle technical college, and described by R. J. Tillyard.

The first discovery of fossils at Ipswich was made by T. H. Simmonds of Brisbane, and the collection was dealt with in a paper by Etheridge and Olliff in 1890. The fossils found were chiefly the elytra of beetles. Later on, B. Dunstan, the Queensland government geologist, explored these beds more systematically, and Tillyard described the insects obtained by him. The horizon of the beds was for a long time in doubt, but the researches of Walkom on the flora and Tillyard on the insects agree in placing them in the Upper Triassic, 'either Rhaetic, or a little older.' The insect fauna is remarkably rich, including a distinct remnant of specialized offshoots of the old Carboniferous fauna of the northern hemisphere; there are representatives of the extinct orders Protorthoptera (*Mesoman-*



Bothriceps major.

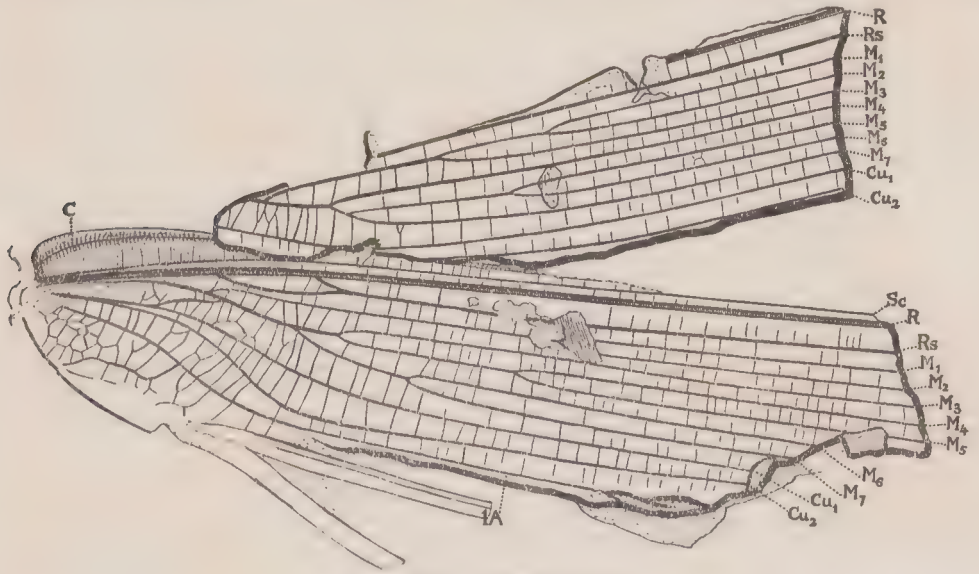
tidion, Mesorthopteron) and Protodonata, the latter being represented by the extraordinary *Aëroplana mirabilis*. A very archaic genus of cockroaches, *Austromylacrites*, is also a member of a Carboniferous family.

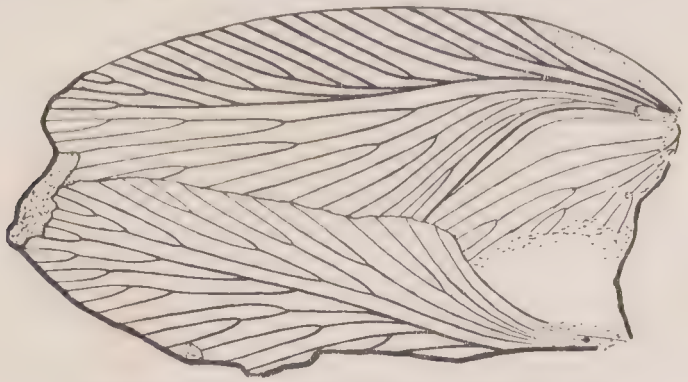
The cockroaches (Blattoidea proper) are represented by a number of species—about 11 per cent of the total—placed in three new genera (*Triassoblatta, Samaroblatta*, and *Austroblattula*) of the family Mesoblattinidae. The most



Aëroplana mirabilis (x 5).

complete of these is *Triassoblatta typica*. The true dragonflies (Odonata) are represented by three genera, *Mesophlebia, Triassolestes*, and *Perissophlebia*, all peculiar to Ipswich. They are the oldest-known true dragon-flies, but appear to have reached a fairly high stage of evolution; *Triassolestes* is in some respects intermediate between the existing Japanese genus *Epiophlebia* and the true Lestinae.

Homoptera represent 19 per cent of the total; all belong to the division Auchenorrhyncha, and are mostly archaic jassids or cercopids. A new



Triassoblatta typica (left and right tegmina, x 7½).

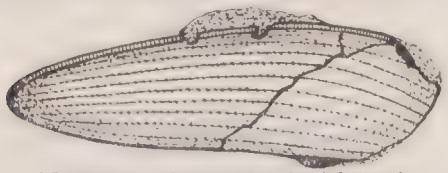
family Ipsviciidae, evidently an early offshoot of the Scytinopteridae, is represented by three fine specimens of the genus *Ipsvicia*; that of *I. jonesi* (plate xxxiv, fig. 2) is an absolutely complete tegmen, with the sculpture beautifully preserved. The genus *Mesojassus* differs little from *Jassus* and its allies of the present day. The earliest-known true Hemiptera are represented by a family of large bugs, Dunstaniidae, containing three genera and species. The finest of these is *Dunstania pulchra* (plate xxxiii, fig. 3). Among the Holometabola the most interesting are representatives of two new orders allied to the true scorpion-flies (Mecoptera). One of these is Protomecoptera, represented by *Archipanorpa* (plate xxxiv, fig. 3), the preservation of which is so fine that the sockets of the hairs and bristles on the wing-veins are perfectly visible; the other is Paratrichoptera, represented by four genera of caddis-like wings, which have been shown to be intermediate between Mecoptera and Diptera. The finest of these is *Aristopsyche superba*. The order may well be directly ancestral to the true Diptera, which first appear in the Lias. True scorpion-flies (Mecoptera) are represented by *Mesochorista*, already referred to above, and by the peculiar genus *Stereochorista*. The lacewings (Planipennia) are represented by two genera of Prohemerobiidae. One of these, *Archepsychops*, is clearly the direct ancestor of the existing genus *Megapsychops*—which, curiously

enough, is only known to occur on Mount Tambourine, a few miles south of the Ipswich beds.

Beetles comprise no less than 46 per cent of the total; most are represented by well-preserved elytra, the dominant genus being *Ademosyne* with about 20 species—probably water-beetles of the family Hydrophilidae. Other families which were probably represented were the Elateridae, Buprestidae, Malacodermatidae, and Cerambycidae, perhaps also the Carabidae and Tenebrionidae; but it is not usually possible to ascertain definitely the family to which even a perfectly preserved elytron belongs.

Other Insect Fossils.—In passage-beds between Palaeozoic and Mesozoic, in the roof of the coal-seam of the Sydney harbour colliery at Balmain, W. S. Dun discovered the impression of a small insect-wing, which has been described under the name *Elcanopsis sydneiensis*. It is the earliest-known record of a true locust (Orthoptera) belonging to the family Elcanidae, abundant in Liassic and Upper Jurassic strata in the northern hemisphere. Insects have also been found in brick-pits at St. Peter's, near Sydney, the horizon being Upper Triassic (Wianamatta shales); most are beetles, but there are also specimens of a fine genus, *Notoblattites*, belonging to the Protorthoptera, and resembling a large cockroach. The poorly preserved remains of a huge insect, *Mesotitan*, probably belonging to the same order, were also found. The fauna of these pits suggests a slightly older horizon than that of Ipswich.

Higher up in the Wianamatta shales at Glenlee near Camden two other species of *Notoblattites* have been found, together with an interesting Paratrichopteron and a Homopteron. At



Ademosyne wianamattensis (elytron).

the very top of the same beds, at Narellan, a single elytron of a species of *Ademosyne*, beautifully preserved, was discovered in mudstone. This horizon is possibly homotaxial with the Ipswich beds.

In the Jurassic beds at Talbragar, New South Wales, a single insect has been found. It was described by Etheridge and Olliff under the name *Cicada lowei*, but is certainly not a cicada, and Handlirsch changed its name to *Griphologus lowei*. It is probably a fairly large Dipteron.

In a marine bed of Cretaceous age near the Flinders River in Queensland a fragment of a fine dragonfly wing was found by R. L. Jack, and described by Woodward in 1884 under the name *Aeschna flindersiensis*. It belongs, however, to the family Aeschnidiidae, only otherwise known from the Jurassic of Europe, and Tillyard has placed it in a new genus *Aeschnidiopsis*.

The Tertiary insect fossils so far discovered are very few. Larvae of ephemerids and Diptera have been found at Vegetable Creek in New South Wales; a fine lacewing (*Euporismites balli*) near Goodna in Queensland; and some fossil dragonfly larvae belonging to the Lestidae in the core of the Duaringa bore in Queensland.

R.J.T.

See R. Owen's *On the Fossil Mammals of Australia* (London, 1876) and *Fossil Remains of Extinct Mammals of Australia* (London, 1877); Lydekker's *Catalogue of Fossil Mammals in the British Museum* (part v, 1887) and *Marsupialia and Monotremata* (1894); A. S. Woodward's *Vertebrate Palaeontology* (1898); Tillyard's *Insects of Australia and New Zealand* (1926).

Palmer, Sir Arthur Hunter (1819-1898), born at Armagh in Ireland on 28 December 1819, and educated at Youghal, in 1838 migrated to New South Wales and for 23 years was employed by Henry Dangar on various stations, ultimately becoming general manager of the Dangar properties. In 1861 he left this work and established himself in Queensland, entering politics in 1866 as member for Port Curtis, and joining the Mackenzie ministry as colonial secretary and secretary for public works in 1867. On the defeat of this ministry he went into opposition for 18 months, and then, displacing Charles Lilley, formed one of his own, which lasted from 3 May 1870 to 8 January 1874—the first stable government formed in Queensland; but his term of office is chiefly notable because during it S. W. Griffith came to the front as a private member. Palmer's next appearance as a minister was under Thomas McIlwraith, whose colonial secretary he was from 21 January 1879 to 24 December 1881. By this time he had wearied of active politics, and gladly retired to the presidency of the legislative council, which he held till his death on 19 March 1898.

Palmer is described by contemporaries as a politician of little education but much sound sense, inclined to bully fellow-members (a remanet, it was said, from his bullock-driving days), but popular nevertheless. He left little mark on the legislation of the colony, though his introduction in 1870 of a bill to give northern Queensland a separate financial existence shows a certain radicalism of temperament. While president of the council he five times administered the government during interregnum (see Governors); he was a trustee of the Queensland Museum, and honorary colonel in the local volunteer forces. (K.C.M.G., 1881.)

Palmer, Sir James Frederick (1804-1871), born in 1804 at Great Torrington in Devonshire, and educated for the medical profession, after some years' practice in London migrated to Melbourne; there he gradually abandoned medicine for the manufacture of cordials, and finally for the business of a wine and spirits merchant. As mayor of Melbourne in 1846 he laid the foundation-stone of the Melbourne Hospital. In September 1848 (after the sham election of Earl Grey for Melbourne) he was elected one of the five representatives of Port Phillip in the Sydney legislature, but vacated the seat in June 1849, and in 1851, being elected by Normanby to the first Victorian legislative council, was made speaker of that body. When in 1856 the colony obtained self-government, Palmer was elected to the upper house and became its president, holding the position until 1870. Apart from his interest in education—he was for a time chairman of the education commissioners—he was for the most part a sedate and dignified figurehead. Resigning his presidentship on 11 October 1870, he died on 23 April 1871. (Kt.Bach., 1857.)

Palmer, John (1760-1833), born in England in 1760, entered the navy when only eight years old, and during the war of the American revolution was for some time a prisoner of war. On 24 October 1786 he joined H.M.S. *Sirius* as purser, came in her to New South Wales, served until she was wrecked on Norfolk Island in 1790, and was on 12 April of that year made by

Phillip commissary-general of the colony. Grose during his lieutenant-governorship granted Palmer 100 acres on the shores of what is now Woolloomooloo Bay, and there he built in 1802 a house reckoned in those days exceptionally luxurious, which was afterwards successively inhabited by Archdeacon Scott and Archbishop Polding. Besides his public duties Palmer engaged in milling—King gave him a mill-site close to government house which annoyed Macquarie exceedingly—and in coastal trading. He owned in 1804 two 30-ton vessels which voyaged as far as Bass Strait, and a third smaller vessel which did not venture farther than the Hawkesbury. He also owned farms purchased from other settlers (nearly 3000 acres in 1807), on which he bred cattle and sheep and grew some wheat. During the mutiny against Bligh he sided with the governor and was imprisoned by the Johnston-Macarthur party, but on Macquarie's arrival was reinstated in his office until 31 March 1810, when he was relieved from duty to proceed to England as a witness for Bligh. During his absence in England Macquarie reorganized the department, and he returned on 6 May 1814 to find himself merely an assistant-commissary-general, and that only because his knowledge would be useful in recovering debts due to the government from pre-Macquarie days. Macquarie, however, became dissatisfied with the whole department, and on 24 January 1819 a fresh reorganization involved the retirement of Palmer on half-pay. By this time he had in one way and another lost all his estates except 100 acres at Parramatta and 1500 acres at Hambledon, near Rouse Hill, which had been granted him in 1818 as compensation when Macquarie resumed his land on the Hawkesbury for a township (Pitt Town). After his retirement Palmer settled down on his farm at Parramatta, was made a magistrate by Brisbane, and became one of the Marsden-Blaxland-Macarthur circle; this led to his dismissal from the bench through a quarrel between one of Brisbane's protégés and the circle, but he was restored to it in 1825 just before Brisbane left the colony. The rest of his life seems to have been peaceful. He died at Parramatta on 27 September 1833, having survived all his fellow-officers of the First Fleet.

Palmer, THOMAS FYSHE (1747-1802), born at Jekwell in Bedfordshire in July 1747, was educated at Eton and Queen's College, Cambridge (B.A., 1769; M.A., 1772; B.D., 1781). In 1781 he gained a fellowship and was made curate of Leatherhead in Surrey, where he met Dr. Johnson and Boswell. About this time he was greatly influenced by the writings of Dr. Joseph Priestley of Birmingham, an advocate of progressive Unitarianism; he renounced his orders, and on 14 July 1783 offered his services as preacher to the Unitarian Society founded by William Christie at Montrose in Scotland. Here he worked from November 1783 to May 1785, then moved to Dundee, where he founded the Unitarian Church which still exists there. He preached frequently at Edinburgh, Glasgow, Arbroath, and Forfar, and founded societies in all these places. By 1792 his sermons had attracted much public attention. In the same year Dundee became a centre of the widespread agitation for political reform, and in 1793 a society (drawn for the most part from the artisan class) was formed and named the 'Friends of Liberty.' Palmer was soon drawn in, and among other work for the society edited a handbill which complained of the extravagant taxation necessitated by a fruitless war and demanded universal suffrage and short parliaments. This was printed at Edinburgh in July 1793, and hundreds of copies were circulated. The government took it very seriously. On 2 August Palmer was arrested on a charge of sedition, and was tried at Perth on 12 September. Both trial-judges summed up against him, the jury held the charge proven, and he was sentenced to seven years' transportation. The conviction, following upon that of Thomas Muir (q.v.), raised a storm of indignation among opponents of the government, and repeated attempts were made during the early part of 1794, by earls Lauderdale and Stanhope in the house of lords and Fox and Sheridan in the commons, to have the sentence reversed.

Palmer, after confinement in the Tolbooth, was sent with Muir to the hulk *Stanislaus* at Woolwich; at first he was put in irons, and placed among the worst felons, but after a month was treated more leniently. On 11 February he, Muir, and William Skirving were sent on board the *Surprize* with a party of convicts bound for Botany Bay; this premature embarkation was intended to forestall further debate in parliament. The *Surprize* left England on 2 May 1794 and reached Port Jackson on 25 October; during the voyage Palmer and Skirving were accused of fomenting a mutiny, and were harshly treated by the vessel's master, but both charge and treatment were abandoned when they landed. Grose gave them houses on the eastern bank of the Tank Stream, and both he and Hunter allowed them as much freedom as was possible. Palmer bought a farm near Muir's on Gore Hill, where he found the soil 'capital, the climate delicious,' and was even stirred to wish 'that all the paupers of Great Britain could make interest to be sent here.' In April 1796, when Skirving was dead and Muir had escaped from the settlement, Palmer was living 'quiet and retired;' and so he continued till the end of his sentence, establishing (with the help of James Ellis, a friend who had voluntarily accompanied him from England) a precarious trade with Norfolk Island. In September 1800, when he was a free man again, he and Ellis bought a vessel in which to return to England, trading among the South Sea islands on the way. Fortune, however, was adverse; they spent six months on the New Zealand coast without securing any cargo, were hampered at Tonga by civil war in the group, were wrecked in the Fijis, and on their way to Macao in China were driven to the Ladrone group (better known as the Mariannes) and held there as prisoners of war by the Spanish governor, Spain being at war with England. Palmer, whose health had suffered greatly during the early part of his sentence, contracted dysentery and died on 2 June 1802. Two years later his body was exhumed, taken to America, and interred in the cemetery at Boston in Massachusetts. In 1844 a monument was erected in memory of Palmer and his companions in the Calton burying ground at Edinburgh.

Palmer's *Narrative of the Sufferings of T. F. Palmer and W. Skirving* was published at London in 1797. *The Trial of the Rev. Thomas Fyshe Palmer, before the Circuit Court of Justiciary . . . on an Indictment for Seditious Practices* was printed at Edinburgh for Skirving in October 1793, and published in Edinburgh, Glasgow, Dundee, Perth, and London. See MUIR, THOMAS.

J.V.C.-B.

Palms, the popular name of the large family Palmaceae, chiefly tropical in habitat; Queensland

may be considered their Australian home. The flowers have six rigid segments in two series (representing sepals and petals), arranged in spikes; sexes distinct in most species; fruit a drupe or berry. Most Australian palms belong to the tribe Arecaceae.

Archontophoenix Cunninghamiana, a tall species with feathery leaves, is the Bangalow Palm of eastern New South Wales, and the Piccabeen of Moreton Bay; its spathes are used by the aborigines for water-containers. *A. Alexandrae* and *A. Beatriceae* are more exclusively tropical. The allied *Ptychosperma elegans* figures erroneously in nurserymen's catalogues as *Seaforthia elegans*, the name given to it by Robert Brown (q.v.). *Drymophlaeus Normanbyi* is the Black Palm of northern Queensland, whose dark-coloured stems are manufactured into walking-sticks. The Walking-stick Palm, however, is *Linospadix* (*Bacularia*) *monostachya*, a slender, erect plant of 6-12 feet that occurs in northern

Clump of young Bangalow Palms, and fruit.

New South Wales and southern Queensland; two equally dainty species of *Bacularia*, *B. minor* and *B. Palmeriana*, occur in northern Queensland.

Of the tribe Corypheae a species of *Corypha* and one of *Licuala* are found in northern Queensland. *Livistona* comprises the cabbage-palms, with fan-shaped leaves. *L. australis* ranges from north-eastern Victoria into Queensland; *L. Mariae*, found in the Macdonnell Ranges and north-west to the Kimberley district of Western Australia, is one of the very few inland palms; *L. Muelleri* and *L. Benthami* are confined to tropical Queensland; *L. Alfredi* ranges from the Hammersley ranges to Kimberley, and *L. Eastoni* also occurs in the Kimberley district.

The tribe Lepidocaryeae includes the genus *Calamus*, weak-stemmed climbers known as 'lawyer-canes,' abundant in tropical Asia. *C. Muelleri*, found in the brush forests of northern New South Wales and Queensland, is armed with innumerable sharp spines and forms almost impenetrable thickets; four other species, all larger than the one just named, are confined to tropical

Livistona Australis, and flower.

Queensland—*C. caryoloides* (Ground Palm), *C. Moli*, *C. australis*, and *C. radicalis*.

The Date Palm (*Phoenix dactylifera*) and Coconut Palm (*Cocos nucifera*) are both exotics. The so-called Kentia palms (*Howea*), much cultivated in Australia and elsewhere, are endemic in Lord Howe Island (q.v.).

Pamphlett, THOMAS, born in England in 1789, migrated to New South Wales about 1819 and was employed as a timber-getter in the Illawarra district. On 21 March 1823 he and three others left Port Jackson in an open boat 29½ feet long with a 10-foot beam to ship cedar from Wollongong. When only eight miles short of their destination, a violent gale forced them to lower sail and run before the wind for five days, and for another six it was impossible to carry sail. Then, under the impression that they had been driven southwards, they steered roughly north-west by the sun for 10 days, nearing land at last on 13 April. That night the boat struck a reef, but was washed over it without damage; three days later the three survivors (one had died of thirst during the voyage) managed to land in a bight, whereupon another gale got up and the boat was stove in. Actually they were some five hundred miles north of Sydney, on an island in Moreton Bay since called Stradbroke Island; still under the impression that they were well south of Sydney, they tried to make their way north, and found the aborigines

on the whole friendly and helpful. Gradually they worked round the shores of the bay, being aided by blacks to cross a large river, and in the end settled down with a tribe whose main camp was near the mouth of the Pumicestone River at the northern end of the bay. Here on 29 November John Oxley, returning from a voyage to Port Curtis and wishing to examine Moreton Bay more carefully than Flinders had done, landed from the cutter *Mermaid* and discovered Pamphlett (the other two had gone off northwards); and, hearing from him of the big river not far south, Oxley entered it on 2 December and pushed his exploration about 50 miles inland, naming it the Brisbane River in honour of the then governor.

Oxley's official report makes no mention of Pamphlett or of the fact that the three castaways were the first discoverers. But John Uniacke, one of Oxley's party, took down from Pamphlett's lips the narrative of his adventures, and Barron Field in 1825 published it in a collection of geographical memoirs. Otherwise we should never have known who really discovered the Brisbane.

Papua, originally known as British New Guinea, is a Territory of the Australian Commonwealth in the south-eastern region of New Guinea, separated from the Australian mainland by Torres Straits, which at this point are less than 100 miles wide. The Territory comprises an area of 90,540 square miles—about a quarter of the whole island—of which 2754 square miles consist of groups of islands scattered along the coast. Its northern boundary, separating it from what used to be German New Guinea and is now known as the Mandated Territory of New Guinea (q.v.), runs from the eastern coast along the parallel of 8° S. lat. to the intersection of the 147th meridian, thence NW. to the intersection of 6° S. lat. with the 144th meridian, and then WNW. to the intersection of 5° S. lat. with the 141st meridian. This purely artificial boundary was devised to correspond roughly with the main watershed of the island. The western boundary, separating the Territory from Dutch New Guinea, coincides with the 141st meridian from the mouth of the Bensbach River to 5° S. lat., except where, between the 6th and 7th parallels, it follows a westerly bend of the Fly River. On the south the extra-territorial boundary of Queensland takes in the islands of Kawa, Adabadanakawa, Matakawa, Moimikussa, Boigu, Dauan, Kaumag, and Saibai, all lying from one to three miles off the Papuan coast.

Discovery and Exploration.—For discoveries before Cook's time, see AUSTRALIA, DISCOVERY OF. In 1793 Bampton and Alt, masters of vessels in the East India Company's service, explored the southern coast as far as the Gulf of Papua, and J. A. d'Entrecasteaux investigated the south-eastern districts. In 1842 Captain F. P. Blackwood in H.M.S. *Fly* surveyed a part of the Fly River estuary and the western side of the Gulf of Papua; at a later date Lieutenant Charles B. Yule in H.M.S. *Bramble* continued the survey to Redscar Bay. In 1849 Captain Owen Stanley in H.M.S. *Rattlesnake* examined the south-eastern end of the island, and in 1873 Captain John Moresby discovered Hall Sound and the harbour of Port Moresby, examined the north-eastern coast from East Cape to Astrolabe Bay, and settled the true shape of the island. Since that time most exploration work has been carried out by government officials; but L. Maria d'Albertis in 1875-7 discovered the Alice River (a tributary of the Fly 460 miles above its mouth), and in 1888 Everill surveyed and named the Strickland River, the main tributary of the Fly. In 1890 MacGregor journeyed 610 miles up the Fly and Palmer rivers, and several years later ascended Mount Victoria (13,121 feet). Other noteworthy expeditions are those of Monckton from the Waria to the Gulf of Papua in 1907, and Mackay and Little's exploration of the upper Purari River and Mount Murray a few years later. In 1910 Staniforth Smith (q.v.) in company with Bell and Pratt visited the upper Kikori district, for which feat he received the Royal Geographical Society's medal. In 1913 Massey-Baker discovered and named Lake Murray near the Strickland River, and Ryan trekked from the Kikori to the Bamu, being severely wounded by natives on his way; in 1914 Chinnery explored the Kunimaipa valley and the surrounding district behind Mount Yule, and Humphries walked from Karema on the Gulf of Papua to Morobe in the Mandated Territory; in 1915 Macdonnell crossed from Cape Nelson over the Hydrographers' Range to Port Moresby, and Skelly in the Gulf division visited the Nabo Range and the Kukukuku country behind Kerema. Lyons, who had already explored the surrounding Gogodara country, in 1917 surveyed the Aramia River. In 1922 Flint and Saunders examined the Samberigi valley behind Kikori, and Austen explored the Alice River district and part of the Star Range in the north-western corner. In 1924 Austen and Thompson completed the examination of the north-western corner between the Palmer and Alice rivers, and the former reached the main Fly River 605 miles above its mouth. Many other officials and a few civilians have done unostentatious but valuable work in opening up unknown parts of the Territory.

Physical Features.—With the exception of the low coral Trobriands and a few other small groups, the coastal islands are mountainous and of volcanic formation; the highest is Goodenough Island, which rises to 8000 feet. On the mainland the eastern end is mountainous; as the mountains extend north-westwards, they rise and unite to form a central chain which is known under various names—Stirling, Hornby, Owen Stanley, Albert Victor, Sir Arthur Gordon, and, in the extreme north-west, Star. Towards the Dutch border the range lies farther and farther inland, and south of it the country slopes rapidly to a plain which is in many parts swampy, especially near the coast. The north-eastern shores, on the contrary, are bold. The highest peaks are found in the Owen Stanley Range—Mount Victoria (13,121 feet), Mounts Albert Edward and Scratchley (each 12,550 feet); many others in that range rise to between 11,000 and 12,000 feet. In the Star Range several peaks are probably over 11,000 feet. The most prominent peak seen from the southern coast is Mount Yule (10,380 feet) in the Owen Stanley Range. In the western division, between Torres Straits and the Fly River, are low, grassy, scrub-covered ridges 100 to 200 feet high; rising hills are not met for a distance of 460 miles from the mouth of the Fly. The greater part

of the western coastal area is covered with mangrove swamps, and along most of the estuaries nipa and sago-palm swamps abound.

The largest rivers are the Fly, Bamu, Turama, and Purari. The Fly has been traversed for 605 miles along its main channel, and along its tributary the Palmer to 610 miles from the mouth. It drains the southern slopes of the Star Range and of the Victor Emanuel Range in the Mandated Territory. The influence of the tide is felt 200 miles up this river, and it is navigable for motor launches for over 500 miles. Its main tributary, the Strickland, joins it at Everill Junction, about 240 miles above the mouth. Other tributaries of importance are the Tedi (Alice), the Elevala, the Tully, the Palmer, and the Black. It is estimated that the volume of water discharged by the Fly River would supply 120 gallons a day to every inhabitant of the globe. At new and full moons the river has a 'bore' (tidal wave) from 6 to 12 feet in height, which commences about 40 miles above the mouth and continues with great force and rapidity for more than 80 miles upstream. For the most part the Fly and the Strickland run through low, flat country. The Purari, next in size, is navigable by launch for over 120 miles. It is supposed to rise in the great ranges along the Mandated Territory boundary, north of the Samberigi valley in the Delta division; its length is probably over 400 miles. It enters the Gulf of Papua by a delta which is connected with a huge network of waterways to the west. The Bamu and the Turama have not yet been explored to their source, but are probably over 200 miles in length. Like the Fly, they are subject to bores. Other important waterways from west to east are: the Bensbach, Morehead, Wassi Kussa, Pahoturi, Binaturi, Oriomo, Kikori, Vailala, Tauri, Lakekamu, Biaru, Angabunga, Vanapa, Laloki, and Kemp Welch; many other rivers have a long course, but are too shallow for use except by canoes. On the north-east four large rivers open into the sea—Musa, Kumusi, Mambare, and Gira. All these natural waterways, together with many excellent harbours (Daru, Yule Island, Port Moresby, Bootless Inlet, Port Glasgow, Fyfe Bay, and Sewa Bay in Normanby Island), are of great value for the economic development of the Territory.

Geology.—What is known of Papuan geology indicates a moderately large range of deposits, passing from the Archaean complex of metamorphic rocks and intrusions to simple late Tertiary sediments, which rest upon Mesozoic, Palaeozoic, and pre-Cambrian rocks. The Queensland Mesozoic rocks apparently extend to Papua, and—although the freshwater series have not yet been discovered there—there seems no reason why the productive coal-measures of northern Queensland should not extend to the upper Purari and Kikori regions. Practically the whole of the Owen Stanley Range, the highland portions of the D'Entrecasteaux group, and the Louisiade Archipelago, make up a huge pre-Cambrian complex; the whole central mountain chain is possibly of the same nature, overlaid with later rocks of Mesozoic age. The late Tertiary beds (which include the oil-field series) are strongly developed in the littoral and the hinterland of the Popo, Vailala, Purari, Era, and other Delta districts. Tertiary beds have been found on the upper Fly, Palmer, and Alice rivers, and these extend into the mountains near the border of the Mandated Territory. The divide between the Sepik and Fly head-waters appears to be composed of Miocene limestone. The Delta division beds, being invaded with lava from the Mount Favenc group, have in valleys where they are exposed too gentle a dip to make it worth while prospecting extensively in this area; and in the northern part of the Western division prospecting would be very expensive owing to the distance of the probable oil and coal beds from the coast. On the south-eastern part of the division, round the Oriomo River, a company is prospecting for oil. Oil was first discovered by Lett and Thomas in the Gulf division in 1911, and some years later the Anglo-Persian Oil Company commenced investigations on behalf of the admiralty and the Commonwealth government, but in 1921 the admiralty drew out, and since then the Commonwealth has continued operations alone, with no success up to the end of 1925. The mineral oil and coal ordinance of 1923 came into force in January 1924, and Papua has been thrown open for prospecting and mining for mineral oil and coal, with the exception of the district lying roughly between the Lakekamu River and Yule Island; several private companies have been operating in the Territory, but so far none have had any signal results.

Mining.—The Territory is rich in minerals. Gold, silver, copper, lead, zinc, iron, osmiridium, gypsum, manganese, and sulphur have been discovered, and topaz and beryl pebbles have been obtained from the upper reaches of the Fly. Brown coal has been found in association with Tertiary sediments, but (as with most brown coals) the percentage of water is too great and the seams are too small to allow of its being handled commercially. Gold is worked on a small scale in the Louisiades, on Woodlark Island, and at the Yodda and Gira goldfields in the Northern division; a small quantity is also obtained at the north-western end of Milne Bay. The export of gold for the year ended 30 June 1925 was £14,980, as compared with £6702 for the previous year and £68,726 for 1922; most of this came from Misima in the Louisiades, where the principal mine was closed down in September 1922. Though the whole central mountain chain is supposed to be more or less auriferous, no payable gold-bearing reef or lode has yet been discovered on the mainland. Dredging areas have been granted on the Yodda and Gira fields, but there are no plants on either. Osmiridium is usually obtained in conjunction with the alluvial gold. Copper is worked at the Laloki and Dubuna mines on the Astrolabe mineral-field, about 20 miles from Port Moresby; a jetty has been constructed at Bootless Inlet, where large ocean-going steamers may berth; the railway from the wharf to the Laloki mine is nearly 8 miles long, but the aerial tramway from the mine is only 3½ miles long, and its construction is greatly increasing the output. At smelters erected close to Bootless Inlet the ore is turned into 'blister' copper for exportation. Ore in sight at the two mines is estimated at nearly 300,000 tons. The ore at the Dubuna mine contains 40 per cent of sulphur, 42 of iron, 7 to 8 of silica, and 5 to 6 of copper, with a small quantity of alumina, about 2.5 dwts. of gold, and 0.5 oz. of silver per ton of ore. The Laloki ore is about 2 per cent higher in iron and sulphur, with less silica. The quantity of copper exported from the field since it was proclaimed in 1906, up to 30 June 1925, is estimated at 14,222 tons and valued at £206,136. None of the other minerals known to exist in the Territory have so far been exploited.

The mining ordinances in force adopt with few exceptions the Queensland mining act of 1898. According to the mining regulations of 1922, a reward claim of a certain extent is allotted to discoverers of apparently payable gold, but no monetary reward is granted.

Meteorology.—In the tropics seasons are classified by the rainfall and the prevailing winds. The wet season coincides to some extent with the period of the north-west monsoon, which blows from December to March; the south-east trade-wind blows during the rest of the year, and this in most districts is the dry season—but at Kikori, Kerema, and Milne Bay the heaviest rainfall seems to occur from May to September during the south-east trades. The change of seasons is always marked by a period of about six weeks during which the winds are light and variable, and frequent thunderstorms occur. The south-east trades in their season blow steadily and continuously; in the early morning the breeze is light, increasing gradually in velocity until about 4 p.m. The north-west monsoon, on the other hand, is accompanied by occasional calms, and sometimes by sudden squalls with heavy rain, locally known as 'gubas.' Fortunately for agricultural enterprise, Papua lies outside the hurricane belt. The notion that the climate of the Territory is unhealthy for Europeans is fast dying out; its falseness has been proved by the fact that many settlers and government officials who have lived there almost continuously for 15 to 20 years still enjoy excellent health. Malarial fever is common, but reasonable precautions and the use of quinine as a prophylactic prevent the attack from assuming a malignant character. In the two most populous centres—Port Moresby and Samarai—malarial fever has been reduced to a minimum by discouraging the breeding of the infecting mosquito in the surrounding districts. On the mountains and tablelands the climate is cool and bracing, and fever is practically unknown. The mean annual isotherm at 17 stations during a series of years is 79°. The rainfall, humidity, and average temperature for the year ending 30 June 1925 at the three principal ports are as under:—

	Pt. Moresby	Samarai	Daru
Rainfall (inches)	43.20	93.06	83.91
Humidity	79%	82%	83%
Maximum temperature	85.9°	82.1°	84.6°
Minimum temperature	75.4°	75.0°	74.9°

Magnetic north is east of true north throughout the Territory; the declination increases eastwards at roughly 13 minutes for each degree of longitude. In 1919 the declination between 144° and 145° E.long. was observed to be 4° 41′, and between 145° and 146°, 4° 49′. Between 147° and 148° a series of observations taken over a period of 1910-20 showed the mean declination to be 5° 19′.

Botany and Agriculture.—An alpine flora does not make its appearance below 6000 feet above sea-level. The indigenous flora seems to be largely blended with Australian, Malayan, and Polynesian types. The most important indigenous plants of economic value are: sugar-cane, rubber (both tree and vine), coconuts, wild nutmegs, tobacco, ginger, bamboos, rattans, areca palms, various species of fibres, bananas, breadfruit, edible nuts, native vegetables (yams and taro), and immense forests of sago and nipa palm. The sugar-cane is remarkable for its wide distribution, and the large number of its varieties, and much of the country is admirably suited for its growth. Some of the finest sugar-cane grown in Queensland has been obtained from Papua. Tobacco grows in several regions, and some obtained by Sir William MacGregor from the upper Fly region was said to be excellent for cigar-making. For some time a tobacco factory operated at Port Moresby, and 'trade' tobacco was manufactured; unfortunately a very poor quality was turned out, but this may have been due to lack of expert knowledge, and not to the poor quality of the leaf. This factory has closed down, but with experts to superintend the drying, curing, and manufacture of the leaf, a large local industry could be established, as over £6000 worth of trade tobacco is imported yearly. Two kinds of sago of commercial value (*Metroxylon laeve* and *M. rumphii*) grow in the swampy districts of the Western, Delta, and Gulf divisions. A company was formed to work the sago on the Paibuna River in the Delta division, and to manufacture power alcohol, but it never developed commercially.

Over 120 varieties of timber trees have been found, of which at least 16 are suitable for commercial purposes; but the Commonwealth forestry expert in his 1923 *Report on Papuan Forestry* says: 'There can be no great development of a timber industry in the natural forests of the lowlands of Papua. . . The future of forestry in Papua is wrapped up in the development of minor forest products. These are tannins, alcohol for fuel, paper pulp, wooden matches, veneers and three-ply, fibre plants, rattans, resins, gums, kino, guttapercha, rubber, vegetable oils, ebony, dyeplants, and medicinal plants.' There are, however, two timber companies at work, one at Manumanu near Port Moresby, the other on the Wami River in the Delta division; most of the timber is used locally.

Cotton is now being planted in large areas, and it is hoped that it will eventually develop into one of the chief articles of export. Upland rice has been grown successfully in the Gulf and other divisions. At the end of June 1925 there were 46,000 acres of coconuts under private cultivation and 2400 acres on government plantations. Other private plantations include 7846 acres of rubber, 3878 acres of sisal hemp, 955 acres of cotton, and about 480 acres of other crops, including rice and coffee; these plantations represent an investment of capital of nearly two millions. In addition, kapok, tea, cocoa, cinnamon, and cinchona have been introduced and grown successfully.

Land Tenure.—Land in Papua can be obtained only under lease for 99 years or less; the annual rent is based upon the unimproved value. The maximum rent for agricultural areas of less than 1000 acres is as follows: first 10 years, nil; next 10 years, 6d. per acre; for every 20 years thereafter the unimproved value of the land is appraised, and the rent raised by not more than one-third. One-fifth of the area suitable for cultivation must be planted with approved plants within the first 5 years, two-fifths in 10 years, and three-quarters in 20 years. For pastoral leases the maximum rent for the first 10 years is nil, for the next 10 years 25s. per 1000 acres, increasing thenceforward by not more than a quarter every 20 years during the remainder of the term. Within the first 5 years 10 head of cattle per square mile, or 50 head of sheep, must be on the land; and double this amount within 10 years and after. For all areas over 100 acres the applicant pays a survey-fee at a fixed rate.

Zoology.—The fauna of Papua, like that of Australia, shows great poverty in mammalia,

though both have a large variety of marsupials. Among Papuan mammalia the rodents include various species of field-rats (*Uromys, Pogonomys, Mallomys rothschildi,* and *M. hercules*), water-rats (*Hydromys*) are also represented. Monotremes—*Zaglossus* and *Prozaglossus* (native porcupines)—are found, and the flying fox (*Pteropus*) is widely distributed. The dingo is also indigenous, but the wild pig, which is widespread, was introduced by early visitors from overseas. Of the many marsupials, tree-kangaroos (*Dendrolagus*) and several species of dorcas kangaroos (*Dorcopsis* and *Dorcopsulus*) have been found, also many species of ring-tailed opossums (*Pseudochirus*), at least two species of cuscus (*Phalanger*), four distinct genera of bandicoots (Peramelidae), and two species of native cats (*Dasyurus*). A peculiar marsupial, the 'pouched rat' (*Phascogale*), is said to inhabit the mainland. Of reptilia two species of crocodile are known; three varieties of turtle abound along the coasts, and fresh-water tortoises are plentiful inland; at least three families of lizards are represented, and salamanders, toads, and frogs are numerous. Among the 50 or more species of venomous and non-venomous snakes many are identical with Australian forms. Death adders (*Acanthophis*), black snakes (*Pseudechis*), whip snakes (*Demansia*), at least half a dozen pythons (*Liasis*), and a bright green constrictor (*Chondropython viridis*) occur, as well as a number of freshwater (*Tropidonotus*) and tree snakes (*Dendrophis* and *Dendrelaphis*). About six species of what is known as the *Toxicocalamus* group may be included among the Papuan varieties.

Of the 500 species of birds found in the Territory, from 50 to 60 genera are characteristic of New Guinea alone; the most noteworthy belong to the family Paradiseidae, which includes 70-80 species of birds of paradise, bower-birds, and manucodes. The scrub turkeys (Megapodiidae) make large communal mounds of earth and leaves, in which they lay their eggs, leaving them to be hatched by the heat generated from the decaying vegetable matter. Two varieties of crested pigeon (*Goura*) have been found, with bodies as large as those of well-grown domestic fowls. Cassowaries (Casuaridae) are found in most of the dense forests below 3000 feet. Hornbills (Bucerotidae) of several varieties are abundant. Among the numerous smaller birds may be distinguished brilliantly-coloured kingfishers, pigeons, parrots and lorries, as well as hawks, owls, ibises, wild ducks, and geese. Butterflies of wonderful colouring and size are abundant and include many rare species; Papua, indeed, is a rich field for the entomologist.

The many varieties of land mollusca show a marked relationship to those of Indian and Malayan regions. Along the eastern coasts, more especially in the Trobriand group, pearls of fine lustre are found, and £19,300 worth were exported during the year ended 30 June 1925. Pearl shell, trocas shell, and bêche-de-mer are also collected, and many hundred tons of these commodities have been exported.

History to 1906.—Though Bligh in 1792 annexed the islands between New Guinea and Cape York on behalf of Great Britain, it was not until 1846 that Lieutenant Yule took possession of the southern part of the mainland of New Guinea. His action, however, was not ratified. On 24 August 1873 John Moresby hoisted the British flag on Hayter Island, and annexed the large islands off the east coast, but the British government again rejected the gift. In 1877 attention was drawn to New Guinea by a gold-rush to the area near Port Moresby. On 4 April 1883 the region east of the 141st meridian was annexed to the Empire by Henry Marjoribanks Chester, a police magistrate in the service of the Queensland government; Sir T. McIlwraith, who ordered the annexation, was stimulated to it by rumours of German designs on New Guinea, but the British government poohpoohed the rumours and disavowed the annexation. In the face of united and vigorous protests from all the Australian government, however, the colonial office agreed to the establishment of a 'coastal protectorate' if Australia would contribute £15,000 towards its upkeep. Before the eager Australian assent to this proposal could reach London, Prince Bismarck had notified the British government of his intention to make annexations on the northern side of New Guinea; and, when in October Gladstone and his foreign secretary, Lord Granville, were at last prepared to annex eastern New Guinea except the strip of north coast between Vulcan Island and the Dutch boundary, Bismarck's protest was sufficient to dissuade them again. On 6 November 1884 Commodore James Erskine was allowed to proclaim a protectorate over the south coast, and on the 16th a German protectorate was proclaimed at Friedrich Wilhelmshafen (now Madang) over the north coast as far east as Huon Bay, Bismarck at the same time notifying the British government that further annexations were in prospect. On 21 December, therefore, Granville extended the British protectorate to include the north coast up to Huon Bay, and the boundaries thus laid down were thenceforth considered final, although they were not strictly delimited until 1908-9. On 17 November 1884 Sir Peter Scratchley (q.v.) was appointed special commissioner for the protectorate, but the colonial office was dilatory about his arrangements, and it was not until 22 August 1885 that he reached Port Moresby to take charge. In December of that year he died at sea of New Guinea fever. John Douglas, then the Queensland government's resident at Thursday Island, filled his place for a time, but on 4 September 1888—New South Wales, Victoria, and Queensland having agreed to shoulder the whole expense—the protectorate was converted into a crown colony and William MacGregor (q.v.) was made first administrator.

MacGregor's policy is discussed under his name; it carried out Scratchley's intentions, and laid the foundation on which Australian policy with regard to the natives of Papua is still based. During his term the Anglo-Dutch boundary (which was nominally the 141st meridian) was varied by following the westerly bend of the Fly River. In 1895 he was made lieutenant-governor, but in 1898 was transferred to Lagos in western Africa. The laxer administration of his successor, George Le Hunte (1899-1903), was marked by the massacre on 8 April 1901 of James Chalmers (q.v.) and Oliver Tomkins, missionaries of the London Missionary Society. They were entrapped and killed by Goaribari natives of the Kikori estuary in the Gulf of Papua; in May the murderers' villages were burnt, but an attempt to recover the victims' heads in 1903 was a failure. In 1903 Le Hunte was transferred to the governorship of South Australia, and his successor, Christopher Stansfield Robinson—the first Australian administrator of the colony—committed suicide when a garbled account of his attempt to recover Chal-

mers's head induced the authorities to cancel his appointment. Francis Rickman Barton (1904-7) was the next administrator. On 1 September 1906 the colony was made a territory of the Commonwealth, under the name 'The Territory of Papua,' and in 1908 was placed under the charge of John Hubert Plunkett Murray (q.v.), who had been the colony's chief judicial officer since 1904, and acting administrator since April 1907. It must be remembered that from 1888 onwards the final authority in New Guinea matters was Australian—in 1888-1900 the governor of Queensland, in 1901 and afterwards the governor-general of the Commonwealth.

Administrative System.—The Territory of Papua is administered under the Papua act passed by the Commonwealth parliament in 1905, slightly amended by an act of 1924. The administration is vested in a lieutenant-governor assisted by an executive and a legislative council; the former consists of eight territorial officials and a non-official member of the legislative council, the latter of the same officials and five non-officials nominated by the lieutenant-governor. One of the nominees represents the interests of the Christian missions. Ordinances of the legislative council relating to native labour, immigration, divorce, and certain aspects of land-policy, are not law until they have been approved by the governor-general of the Commonwealth; on the other hand, no Commonwealth legislation extends to Papua unless the act explicitly says so. The seat of government is Port Moresby. The lieutenant-governor has under him a government secretary, a treasurer (who is also chief postmaster and collector of customs), a commissioner for native affairs, a director of lands, surveys, mines, and agriculture (who holds a dormant commission as administrator in the absence of the lieutenant-governor), a chief medical officer (also chief anthropologist), a director of public works, and an official secretary to the lieutenant-governor. These, with the deputy chief judicial officer, are official members of the executive council. The staff also includes a chief geologist and surveyors and land-buyers. The chief judicial officer or his deputy presides over the central court, with a jurisdiction analogous to that of the high court of Australia; appeals from the central court lie to the high court, whose decision is final. For administrative purposes the Territory comprises eight divisions, five of which have subdivisions; they are Western (with headquarters at Daru), Delta (Kikori), Gulf (Kerema), Central (Port Moresby, with sub-stations at Yule Island and Rigo), Eastern (Samarai, with sub-station at Abau), South-eastern (Misima, with sub-station at Losui), North-eastern (Tufi, with sub-station at Baniara), and Northern (Buna Bay, with sub-stations at Iom and Kokoda). Divisions are in charge of resident magistrates, and assistant resident magistrates look after the sub-stations. In each division and subdivision are usually stationed detachments of armed native constabulary under white officers.

The Territory's tariff applies to most imports, including Australian. The ports of entry are Port Moresby, Samarai, and Daru, where also there are post-offices and branches of the Commonwealth savings-bank. At Port Moresby and Samarai there are wireless stations in touch with Australia. Up to August 1925 the Commonwealth navigation act—which explicitly applied to Papua—confined external trade to Australian ports and Australian shipping, and the steamer-service was monthly to and from Sydney. Since that date the application of the act has been withdrawn, and non-Australian shipping firms are allowed to deliver and lift cargo. The coastal service employs two steamers which ply monthly along the coast, and a number of small craft which maintain communication between the head-stations and the plantations in each division. There is also an irregular mail between Daru and Thursday Island.

Financial and Statistical.—At 30 June 1925 (excluding the annual Commonwealth grant of £50,000) the total revenue was £90,798, chiefly derived from customs and excise duties. This is the first real increase since the war. The exports—consisting mainly of copper, gold, pearls, copra, rubber, cotton, and sisal hemp—showed an increase over the previous year of £128,221, the total value amounting to £367,629; and the total value of imports—consisting chiefly of tobacco, prints and other textiles, agricultural products, groceries, metals, and machinery—was estimated at £459,080.

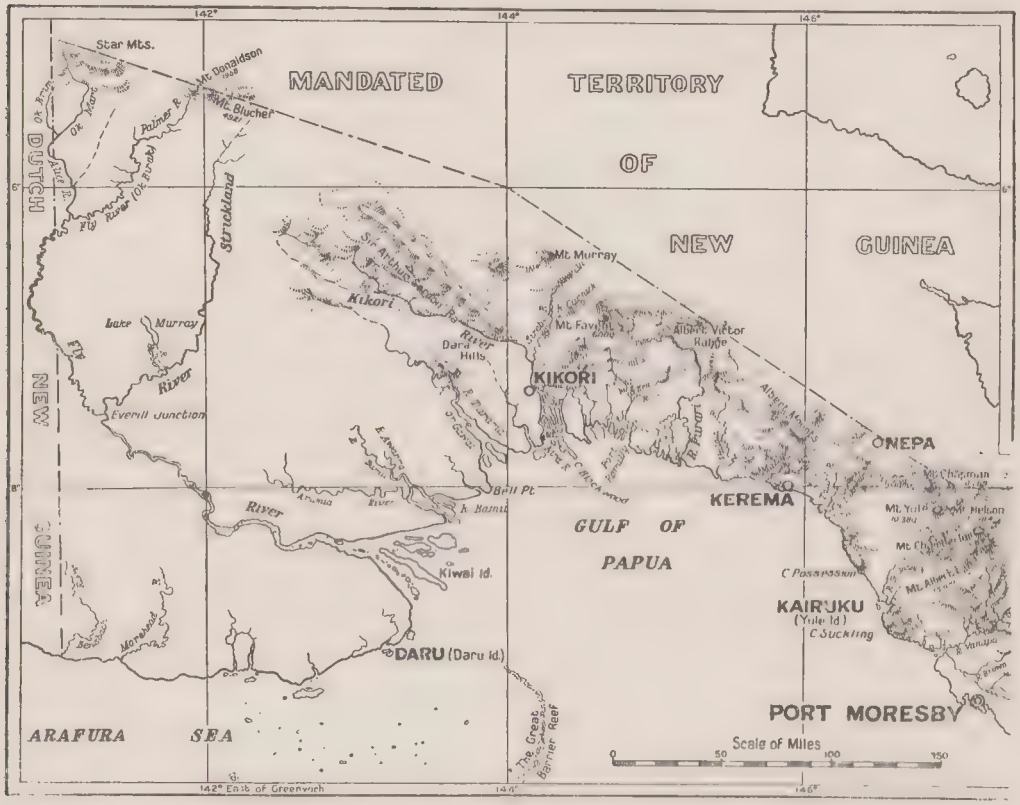
The present white population is a little over 1000; the native population is estimated at 300,000.

Missions.—Five mission bodies operate in the Territory; in order of seniority (*a*) the London Missionary Society, whose sphere of influence includes the whole southern littoral except Yule Island and the Mekeo districts; (*b*) the Roman Catholic Mission, working on Yule Island and Mekeo, which has extended its stations farther inland than any other mission; (*c*) the Methodist Missionary Society, whose sphere is the large islands off the south-east mainland; (*d*) the Anglican Mission, whose stations extend from Chads Bay to the border of the Mandated Territory; (*e*) the Seventh Day Adventists, who operate in the mountainous district behind Port Moresby.

Relations with the Natives.—The Commonwealth in 1906 took over 'a large country, not very fertile, but still capable of considerable agricultural development, and of almost untouched mineral resources—a territory consisting largely of impenetrable swamps and inaccessible mountains, and very scantily populated, principally by head-hunters and cannibals, or at best by semibarbarians only separated from utter savagery by a short generation of very superficial civilization.' Australian policy has since resulted in the advance in civilization of thousands of aboriginal natives (numbers of whom are used by the missions as native pastors, and by civilians and the government in carpentering, plumbing, engineering, and other skilled-labour industries); in the increase of the area under cultivation; in mining development; and in the expansion of exports, imports, and revenue. All this has been done despite the war and the navigation act. And the policy has been, and is, Sir Hubert Murray's.

MacGregor in 1888 initiated a policy inspired by the belief that 'one of our first duties lay in dealing justly and righteously with the native inhabitants.' This has been the basis of the Commonwealth's policy also; it is designed, first, to protect the native in his contact with Europeans, and, without destroying his social life, to lead him to a higher state of civilization; secondly, to make the Territory self-supporting. When Murray took charge, most of MacGregor's actual work had been obliterated during the unsatisfactory period following his administration, and the report of a Commonwealth royal

commission led people to expect too great a return from the soil, and the amount of native labour available; many, therefore, who had invested in Papuan land on the strength of this report blamed the government for their unprofitable returns. The supply of labour is uncertain, and during the next 20 years the number available will probably not exceed 15,000; still, it is possible that the introduction of cattle and labour-saving machinery may compensate for any future shortage. An ordinance prohibiting the entry of coloured races except under certain conditions is intended to prevent the extinction of the natives by an influx of Asiatics. A native labour ordinance fully protects the native as a labourer and causes no undue hardships to the employer. Most native labour is employed under the indenture system, which, though objectionable as a permanent institution, is needful until the natives are better educated. Some settlers favour indenturing women for work on plantations. Others believe better results would be obtained by allowing labourers and their wives to live in villages on the plantations; the great drawback would be that, besides destroying the social life of the existing villages, it would eventually convert the natives into a wandering, landless proletariat. Further,

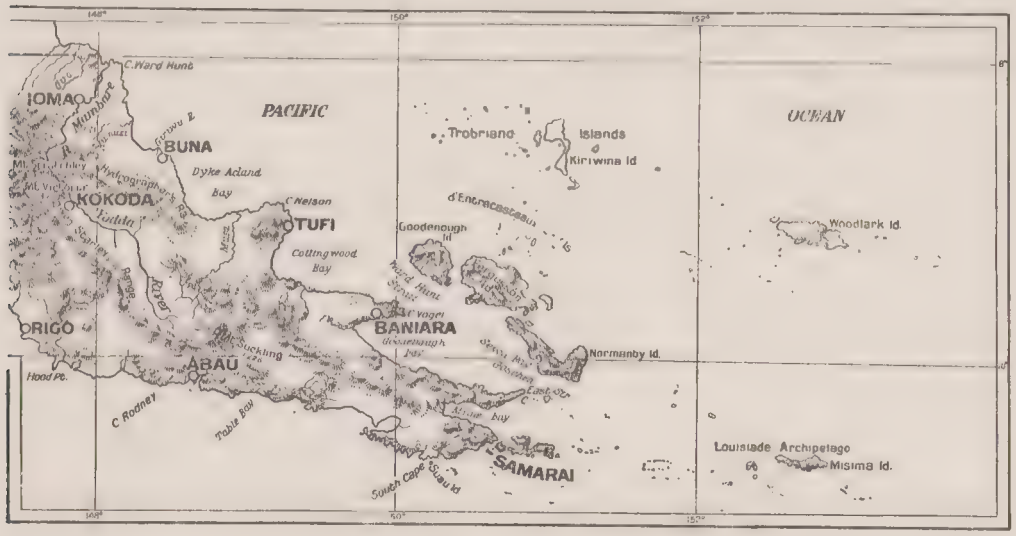


since the advent of the white man, the civilizing influence of the missions and the suppression of harmful customs by the government have done away with many recreations and ceremonials that occupied a good deal of time; some occupation must be found for the natives to prevent them from degenerating into a wretched idleness, and a native plantation ordinance encouraged them to cultivate their own plantations with the assistance of qualified instructors. To provide for their further education, the taxation ordinance of 1919 provided that all male natives between the ages of 16 and 36 (with certain exemptions) should be taxed at rates varying from 5s. to £1 per head, in specified taxable districts—indenture labourers are taxed 10s. per head. The money thus obtained forms a trust fund out of which grants are made (*a*) to missions for primary and technical education of the natives, (*b*) for establishing and maintaining native plantations under governmental supervision, (*c*) for the study of anthropology, (*d*) for the medical care of the natives, (*e*) for village improvements, and (*f*) for the payment of a 'family bonus' of 5s. to the mothers of four living children, with an additional 1s. for each additional child. The balance at credit of the trust fund on 30 June 1925 was £31,449. As time goes on this fund will be largely utilized to establish technical and general government schools for the sole benefit of the natives. Of the proceeds from native plantations about half is credited to the trust fund; the owners are given the balance and exempted from taxes for the year. Rice, cocoa, and other plantations have been started in many divisions, and a rice-mill has been erected at Port Moresby to deal solely with native crops. An anthropologist travels over the country, studying native customs and learning the native view-point; it is hoped that in this way useful or harmless customs may be incorporated with the general policy; the material will also be useful to officials, giving them a more sympathetic insight into native problems, so as to avoid unconscious offences against unknown tribal traditions.

The 'punitive expedition' against whole villages is no longer used, and criminals are arrested without others being involved in their punishment. The Papuan is as secure in his land, and as assured of his freedom, as he was when Commodore Erskine proclaimed the Protectorate; at the same time he is shielded from the ill-effects of alcohol in his contact with the white man —which was the result Sir Peter Scratchley had hoped to achieve.

Anthropology.—The natives of Papua are comprised in three main groups—negritos, Papuans, and Papuo-Melanesians. The *negritos* (a class which includes the pygmies) are a very short, woolly-haired, broad-nosed, broad-headed people found throughout the mountainous country in the north-western corner, in the Upper Fly district, and also round Mafulu and Mount Yule much farther east. The eastern tribes are not pure-bred; probably during some migration they were cut off from the main body to the west, and then were encircled by Papuans, from whom they adopted many customs. The purer type of negrito uses the bow and arrow, and lives in a small square house built on piles, with internal compartments and a sunken fire-place. Along the lower Alice River these piles are often from 40 to 50 feet long, towards the mountains only 9 to 15 feet. The pygmies of the Star Range closely resemble those found in the Tapiro Mountains of Dutch New Guinea. Their height varies according to their purity, but some have been found below 4 ft. 10 in. The dress of the eastern negrito man is a perineal band of bark cloth, and the woman wears a strip of fibre; among the north-western tribes men wear a small nut or part of a gourd as a penal case, women a very short reed 'petticoat.' Arrow-proof cuirasses of plaited rattan have been found in the north-western district. Tattooing is unknown. Boars' tusks, dogs' teeth, and 'Job's tears' seeds sewn into a wide forehead-band, are the main articles of personal adornment. Small jaw-ended cylindrical drums are used in the north-west. As usual among negritos, fire is made by the strap-saw method of rubbing a strip of dry skin from a rattan against a cleft stick. The dead of the north-western tribes are buried in bundles resting on forked sticks, those of the eastern on high burial-platforms; in both regions burials are occasionally made in the earth. Besides bows and arrows, stone clubs are used, and netted string 'dillybags' are manufactured. Bamboo tobacco-pipes are often smoked. The negrito makes gardens in which grow taro, yams, sweet potatoes, and bananas. Wild pigs and cassowaries are hunted, and form the main meat diet. Pigs and dogs are kept as domestic animals. Negrito decorative art is extremely crude, consisting of simple geometric designs—mainly combinations of straight lines.

The more or less true *Papuans* inhabit the coastal and interior lowlands west of Cape Possession. They are distinguished by a great variety of dialects, all belonging to 'Papuan' languages. Physically, they are taller than the other groups; their hair is dark and woolly, and the head dolicocephalic; the face is long and narrow, the nose long, broad, and often



hooked—which gives a pronounced Semitic appearance. Their weapons are the bow and arrow and the stone club. These Papuan-speaking peoples may be classed in six 'culture districts.' (1) in the Middle Fly region, including Lake Murray and the lower Strickland, the tribes grow tobacco and chew betel-nut; build men's ceremonial houses; fashion stuffed human heads; manufacture stone-headed clubs and large hour-glass-shaped drums with handles (see MUSIC, PAPUAN); and carve and paint on trees. Their canoes are long and narrow, without an outrigger; and they have a distinctive type of decorative art, in which vegetable forms combined with spirals appear to play a great part. (2) The Lower Fly (Kiwai) district is characterized by long ceremonial houses, head-hunting (now suppressed), elaborate initiation ceremonies—in which the bull-roarer plays an important part—and kava-drinking, probably of exotic origin. The decorative art consists of rectilinear patterns and representations of animals. (3) The Aramia River (Gogodara) tribes have customs resembling those in the Lower Fly, but kava has a greater signification in all their ceremonies, and very elaborate trappings are used in them. Human heads are decorated, and used in certain dances. There is probably a *manes* cult. Gogodara canoes resemble those of the Middle Fly in shape, but the prows are carved to repre-

sent crocodiles and birds. The carvings of these people are perhaps the best among all Papuan-speaking tribes of the Territory, and most of their carved work is used in connection with their ceremonies. The characteristic decoration is a series of three concentric circles, unclosed in the lower part. (4) On the Turama and Kikori rivers all the tribes have similar initiation ceremonies as well as an Agiba cult (skull shrine); the men's ceremonial houses are somewhat similar to those of the Lower Fly. The natives used to be, and in one or two isolated cases still are, head-hunters. (5) Among the tribes of the Purari delta the 'kopiravi' cult is the outstanding feature. Kopiravi are basket-work monsters which are placed in a screened-off end of the great ceremonial houses, and are only used in certain ceremonies. Their religion appears to be a combination of totemism, head-hunting, cannibalism, and an ancestor-cult. (6) The Gulf of Papua has a distinct cult, the 'kovavo' mask, with which novices are invested at certain initiation ceremonies. At certain rites human-face masks are worn, clearly showing association with an ancestor-cult. Their initiations (which take place only at long intervals) are elaborate and prolonged. The western Papuans have a patrilineal kinship and inheritance. The decorative art of districts 4, 5, and 6 consist mostly of human-face designs.

The natives of the north-eastern coast, from the Waria River to the Musa, may be included among the Papuan types, but other influences have altered their customs very considerably. The use of the bull-roarer in certain ceremonies shows an alliance with the western Papuans, but the 'big feast' ceremonies, and the making of coiled pottery in some parts, undoubtedly show an exotic—probably a Melanesian—culture.

The *Papuo-Melanesians*, found east of Cape Possession, are dealt with below.

See Moresby's *Discoveries in New Guinea* (1876) and *Two Admirals* (1913); D'Albertis's *New Guinea* (1880); J. P. Thomson's *North-east Coast of British New Guinea* (1891) and *British New Guinea* (1892); A. C. Haddon's *Headhunters* (1901); Abel's *Savage Life in New Guinea* (1902); Staniforth Smith's *Handbook of Papua* (1903); Seligmann's *Melanesians of British New Guinea* (1910); R. W. Williamson's *Mafulu* (1912); J. E. Carne's *Coal, Petroleum and Copper in Papua* (1913); J. H. P. Murray's *Papua* (1912) and *Papua of To-day* (1925); Beaver's *Unexplored New Guinea* (1920); Monckton's *Experiences of a New Guinea Resident Magistrate* (1921) and *Last Days in New Guinea* (1922); B. Malinowski's *Argonauts of the Western Pacific* (1922); Humphries's *Patrolling in Papua* (1923); J. H. Holmes's *In Primitive New Guinea* (1924); and E. B. Riley's *Among Papuan Headhunters* (1925). Sir J. H. Murray's official reports on three-power rule in New Guinea (1919), native problems (1921-2) and recent explorations (1923) are valuable, as are the reports on Papuan forestry by Lane Poole (1923), geology by Evan R. Stanley (1923), and anthropology and health by Strong, and the annual *Reports* of the administrators of British New Guinea (1888-1906) and Papua (1906-1925).

L.A.

THE PAPUO-MELANESIANS.—This group inhabits the eastern end of the island, but detached tribes are found at several points along the north coast. Thanks mainly to the researches of Dr. Seligmann—who classified and described subdivisions of the group—the Papuo-Melanesians are much better known than any other natives. As their name indicates, they are racially and culturally akin to the Solomon Islanders and to most of the tribes inhabiting the Bismarck Archipelago. They are brachycephalic, light brown in colour, with rounded face and fuzzy hair; some tribes grow an enormous mop of hair. The women wear thick grass petticoats made of frayed palm or banana leaves, the men only a pubic leaf or perineal string. They make pottery and basket-work, and use well-decorated wooden implements, their decorative art being based on conventionalized animal motives and characteristic spirals. Magic is of immense importance to them, economically and socially. As a rule tribal authority is based on sorcery, the headman being either himself an expert in evil magic or having one at his disposal. Black magic involves the charming of some substance and letting the victim consume it; but remains of food, nail-parings, or hair-clippings are never used for this purpose. They do not fear ghosts; their fears at night or in haunted places concentrate upon malignant living sorcerers or witches, and upon maleficent spirits of non-human origin. As a rule, the dead are buried in the earth, though tree and platform burial are also known in some tribes. The skulls and bones of the buried are sometimes unearthed and used as relics.

The Papuo-Melanesian languages show a distinct linguistic type, akin to the languages of Malays, Polynesians, and Malagasy. The tribes are obviously immigrants from the east and north-east; their purest type occurs on the islands off the eastern coast. The natives of the Trobriand archipelago are in many ways typical. Their fishing-villages are irregular, not very clean, and crammed near the shore. Clean, well-made paths among low scrub and yam-gardens lead to the inland villages, built on the same principle but much more regular and cleanly. Each village stands in a grove of old fruit-trees, which tower above the low scrub or garden-land and make the site of a village visible for miles around. Within this grove the houses are built in two concentric rings, which enclose a circular place in the middle and a street between the outer and inner ring. The inner ring consists of store-houses for yams, built on piles, and as a rule much higher than the living-houses; these are all in the outer ring, stand on the ground, and consist practically of a large thatched roof with a profile like that of a Gothic arch. The chief's house and his yam-house are much larger than the others, and are specially decorated. The chiefs are also privileged to wear certain ornaments, and must always be above the rest, so that commoners crouch or squat when in their presence.

Order, morals, and good form are based upon family and kinship, as well as upon the political constitution of the community. Family life is essentially normal; husband and wife are equally fond of the children, and bring them up and educate them in necessary arts, crafts, and knowledge. The basis of kinship is matrilineal—the child belongs to his mother's family, clan, and village community, inherits mainly from his maternal relatives, and is not considered to be related by blood to his father. The latter's share in procreation is indeed not known to the natives, who believe that a diminutive baby is inserted by a spirit into its mother's womb, where it develops till birth.

Each village community has one headman, makes common gardens on a definite area of garden-land, and acts in many other respects as one unit. A headman of an important village has large sway over a whole district, and may be called a chief in the narrower sense of the word. Four totemic, exogamous clans exist in the Trobriands, and every native belongs to

one of them. Each clan is subdivided into sub-clans. The natives believe that in ancient times human beings lived underground, and that humanity originated by the emergence of groups. Thus at a certain spot called Labai, a man and his sister came out of a hole in the ground; the man carried a white pigeon in his hand and was fully dressed with the distinctive ornaments of a chief. He was the first male member of the chief's clan, of which the pigeon is the totemic animal, and which has a paramount influence all through the Trobriands. But, though he was the first member of the clan, he was not an ancestor, because his children did not belong to his clan: under exogamy he had to marry a girl from another clan, and the offspring of this marriage belonged to that of the mother.

In personal association, far from being an ill-mannered barbarous savage, the native proves himself well-bred, refined in manners, and perhaps somewhat too strict in formalities of behaviour, which to a white man seem heavy and punctilious. Even their amusements are treated seriously and ceremoniously. Thus dancing, which is naturally a passion with them, is associated with an annual festival about a month long, during which the spirits of the dead are believed to return to the village, receive offerings of food and valuables, and rejoice at seeing dances performed in full ornaments every afternoon and informal dances done at night. Sometimes a community, at the instigation of its chief, arranges an extension of the dancing-period, and the performances last for a couple of months, other people coming to admire and to exchange presents. Dancing is almost always accompanied by songs—rhapsodies or epics relating to important historical events, such as daring voyages, bloody fights, or magical miracles. Natives as a rule dance in a circle, the orchestra, singers, and drum-beaters standing in the middle, the dancers in single file spinning round in slow or fast movement, according to the nature of the dance.

Sometimes a community will arrange an additional feast (also month-long), always inaugurated and ended by a great feast and distribution of food, with one or two feasts in between. During some of these the women of the village assemble each evening and sing songs as a choir; at others the men ceremonially display ornaments of red shell-disks and exchange them; or some public game (usually a tug of war) is played every evening, or the natives will ceremonially make, wear, and exchange wreaths of a sweet-scented white flower. Even if no festive period is ceremonially inaugurated and carried on, in each village there is much play towards and at full moon. Women sit down in groups to sing, men gather and talk, children play noisily on the central place, and the youth of both sexes engage in one or another form of love-making. Dancing is performed only during the midwinter dancing-season or a special festive period; but very often the adults join in the playing of the children, and the whole village resounds with screams of laughter. Picnics (especially to the seaside, with surf games and 'mixed' bathing), walks in parties or couples, and visits to other people's villages and gardens, are much practised and enjoyed. On wet, cold, or windy nights pleasures of a more literary character are substituted—the relation of humorous or serious fairy-tales, many of which would not bear repetition in the presence of the prudish.

In all amusements the element of sex plays an important part. Masters of dancing gain the women's admiration and, as a rule, take advantage of this to embark upon a love-affair; feasting and all other amusements are also opportunities for love-matches and intrigues. Young men sometimes make expeditions to other villages, but always run the risk of detection by a jealous rival from that village—whereupon punishment follows. There are also regular excursions of young girls from one village to another, where they choose their partners and spend a night with them. Intrigues are carried on upon the principle that presents have to be given by boys to girls—no girl's love is disinterested. The men often employ love-magic, regardless of age and position. Married women, however, must be faithful in all circumstances, or they are punished severely. Marriage is usually the result of a long and fairly permanent intrigue. There is hardly any ceremony; the girl moves into her husband's house, the two eat a meal and henceforward publicly live together. There is an exchange of presents between the bridegroom and the girl's family.

The Trobriander is extremely industrious and conscientious, takes a definite pleasure in his work, and is ambitious about the results. To be called lazy is a great offence. Everybody is supposed to have a good garden, and in the gardening-season men, women, and children spend the better part of the day in the gardens, all working according to age and capability. In coastal villages the men go out for days on fishing expeditions, while the women are busy collecting shell-fish; when the men come home the women prepare food and occupy themselves with domestic duties, while the men carve or follow some other industrial occupation. The quality of their work is good, and the workmanship of their implements fine, the form being often strikingly beautiful in proportion and finish as well as in decoration and colour. Houses and boats are constructed with a distinct regard to certain aesthetic canons of which the natives are well aware, and the chiefs' houses as well as the sea-going canoes are decorated with excellent carvings. In the yam and taro gardens the ground is scrupulously cleared and kept clean from weeds, the bulbs are planted methodically, and each individual plant is looked after by the owner; gardens are divided into neat squares by sticks placed on the ground, the supports of the yam-vines are made high and strong, and certain constructions which play a rôle in garden-magic are conspicuous and beautiful from the native point of view, but have no practical purpose. All this is done in order to satisfy ambition: everybody knows that his garden will be examined by his fellows and criticized, admired, or derided, according to its merits; and there is nothing that the native likes more than praise, or dislikes more than censure—and especially ridicule.

The Trobriand islander takes a great interest not only in the production of wealth, but also in wealth itself. His outlook is highly materialistic and essentially bourgeois, and he values a man according to worldly possessions. He lives in a state of crass, though primitive, plutocracy, where wealth is the basis of social power, where love, affection, respect, and sorcery have to be bought, and can be bought by all who bid high enough—with one limitation. Wealth, the instrument of power and the basis of social importance, is accessible only to headmen and chiefs, and great wealth to chiefs of the highest rank only. The chief receives the lion's share

of food (especially of garden produce), and no one else is allowed to store large quantities of yams. Now he can, and will, exchange yams for certain objects of value (vaigua, as the natives call it)—large ceremonial blades of green volcanic stone, arm-shells made from *Conus millepunctatus*, and strings of red shell-disks. These objects represent capital, but not currency: they cannot be exchanged at will for objects of immediate consumption, but must be given away by the chief on certain occasions, this practice being incidental to the exercise of his power. Thus when a chief organizes a feast or a communal work (making a canoe, building a house, forming a sailing expedition, making a communal clearing of bush for gardens), or when he needs the services of a sorcerer, he has to give a present of vaigua. But these presents return to him sooner or later in the form of specific tributes—so that capital, broadly speaking, remains always in the hands of chiefs and can never accumulate with commoners.

The economic value of magic is noteworthy. For gardening, each village has a specialist who must belong to that village; as a rule he is the chief or the chief's near kinsman, and is heir to generations of garden magicians. He has to settle dates, decide as to the site of prospective gardens, and in general to act as an expert. Each successive stage of garden-work—clearing, burning, planting, weeding, and harvesting—has to be inaugurated by a special ceremony. Corresponding magical systems exist with regard to certain forms of fishing, as well as with regard to the building of canoes and to certain industrial activities. The art of carving, very important among the Trobriands, rests also on the idea of magical efficacy: each aspirant to the art has to be initiated by a master-carver with a magical formula and rite. Finally, trading and sailing, both conspicuous in the social life of the Trobriands, are associated with magic. The natives export many articles and import others, but their main trade—or at least the form of trade which is by far most important in their own eyes—is the exchange of valuables. The islands east and north-east of the Papuan mainland are linked together in a traditional trading circuit, where two types of articles constantly move in opposite directions. Strings of red shell-disks (called soulava in the Trobriand language and bagi in the dialects about Samarai) travel from the Trobriands eastward to Woodlark Island, and return via Misima, the Louisiades, Dawson Straits, and Amphletts to the southern and south-western villages of the Trobriands; at each stage they are exchanged for arm-shells of a corresponding value. Practically all the valuables of those two classes constantly travel, so that no man can possess any of them for more than, say, a couple of months; on the other hand, he becomes successively the owner of a numberless series of valuables, some of which return to him from time to time. No barter or higgling is allowed in the kula (as this form of trading is called), and it is a matter of honour and ambition always to give a fair equivalent for the value received. As partners in this perpetual motion of circular trading only headmen and chiefs are admitted. Magic is considered essential to successful trading expeditions, nor would anyone dream of embarking upon one without performing the elaborate system of kula-magic. There is also rain-magic, as well as magic for making fine weather and wind.

The mechanism of magic is, as a rule, simple. The main virtue resides in the magical spell, which must be well known. If you know the spell you are a specialist, but very often this privilege is hereditary and cannot be acquired by an outsider. A specialist must observe certain taboos, some permanent, some incidental to the rite—which, as a rule, consists in the reciting of the spell over some substance, generally vegetable matter.

An important department of magic is that directed towards production or removal of illness. All serious disease is regarded as an extraneous something, introduced into the organism by sorcery. The technique for producing disease is the same as that of magic in general: a spell is muttered over edibles, which are then given to the unsuspecting victim—or else leaves are chanted over and then burned in a clandestine manner, so that the fumes reach the victim. For each ailment there is a specific spell; native pathologists enumerate from 20 to 30 different complaints, some of which obviously correspond to rheumatism, throat-disease, large sores, and skin-eruptions, whereas others are classified according to mysterious principles disregarded by modern medicine.

Besides the diseases produced by sorcerers, acute and fatal sickness results from the operations of a witch. Some women can make themselves invisible and travel through the air. They will attack people, eat away the tongue and the lungs, and thus deprive the victim first of reason and consciousness (which dwells in the tongue) and then of life, which ceases when you breathe no more. Illness may also follow upon any break of one of the numerous taboos associated with native social life—especially upon the break of the taboo which forbids sexual intercourse between people of the same clan. Fortunately for those who are in love with girls of their own totem, there exists powerful magic which prevents or cures illness thus contracted. Malignant tree-spirits also produce disease, and are dreaded. There is, however, no fear of any other spirits; the ghosts of the departed do not permanently dwell near their former abode, and never do any harm to anyone. Normally the baloma (ghosts) remain on the island of Tuma north-west of the archipelago; there, undisturbed by the living and letting the living alone, they lead an existence practically identical with their previous life. Only once a year, as has been mentioned above, do they interrupt this normal existence in Tuma and return for about a month's holiday to their former villages, where they are welcomed and entertained. They are often invoked in the magical spells, but are not considered in any way malignant.

In general the natives are not very much afraid of darkness, and a man (or even woman) will walk alone at night from village to village. In this respect they differ noticeably from the natives of the mainland. B.M.

Paradise-fish. See SNAPPER.

Pardalotes. See DIAMOND-BIRDS.

Parinarium, a tropical genus of the family Rosaceae, consisting of trees with alternate leaves. Two species are indigenous to Australia. The calyx-lobes are 5; petals 4-5; stamens numerous; fruit a spherical drupe, with a bony inner coat. The aborigines use the succulent drupes of *P. nonda* (Nonda Tree) as food. The ripe fruit resembles a yellow egg-plum, and tastes somewhat like a mealy potato, but has

a trace of that astringency so common in Australian fruits. Leichhardt found the fruit in natives' dilly-bags and in the stomachs of emus.

P. nonda.

The tree has a soft, close-grained, yellow timber, very strong and easily worked.

Parker, HAROLD, born at Aylesbury in England in 1873, was brought to Brisbane at the age of three, studied wood-carving and modelling at the local technical college, and made the wood-carvings for the New South Wales forestry exhibit which was shown at Chicago in 1893. In 1896 he went to London, and studied under W. S. Frith at the old Lambeth school of art; his first success, 'Ariadne,' which was exhibited at the Royal Academy in 1908, was bought for the Tate Gallery for £1000. He modelled and carved two large marble groups which flank the entrance to Australia House in the Strand, London. He is a regular exhibitor at the Academy, and has also shown at the Old Salon, where he was awarded a *mention honorable* in 1910. The marble head 'Esther' and 'The First Breath of Spring' (both in the Brisbane gallery) were carved direct from life. A bust of his father, carved from Queensland marble, was shown in the Australian pavilion at Wembley. A reduced replica of 'Ariadne' is in the Melbourne gallery. W.M.

Parker, SIR HENRY WATSON (1808-1881), born at Lewisham in Kent and educated for the law, was brought to New South Wales in 1838 by Sir George Gipps as his private secretary. He married into the Macarthur family, was in May 1846 appointed to the legislative council (of which he was made chairman of committees), and, when Gipps left the colony in July of that year, decided to stay in Australia. He retained his chairmanship through three councils, and, when in 1856 the new constitution came into force, stood for Parramatta and represented that constituency in the assembly from March 1856 to December 1857. He lost the speakership by a single vote; then, after four months of partisan quarrels which used up two ministries, he was made premier as the man most likely to reconcile the opposing factions. During his administration the parties were almost equal in number, and in August 1857 his ministry was thrice defeated. He resigned early in September, but before the end of the year had retaliated on his successor, Charles Cowper; parliament was therefore dissolved, and Parker determined to retire from politics altogether. Soon afterwards he returned to England and settled at Richmond, where he lived till his death on 2 February 1881. (Kt.Bach., 1858; K.C.M.G., 1877.)

Parker, SIR STEPHEN HENRY, son of Stephen Stanley Parker of York in Western Australia was born on 7 November 1846, educated at Perth, and called to the local bar in 1868. From 1878 to 1890 he sat in the legislative council, was recognized as the leader of the agitation for responsible government, and was a member of the delegation that went to England to secure the passage of the bill granting it. From 1890 to 1892 he represented York in the lower house, and was then nominated to the council, holding his seat there till 1897. In 1892-4 he was colonial secretary and minister for education in the Forrest ministry. In March 1900 he was sent to London as a delegate from Western Australia to watch the progress of the Commonwealth bill through the Imperial parliament. In September 1901 he was appointed a puisne judge of the State supreme court, acted as president of the arbitration court in 1904-6, and in the latter year was made chief justice. He left the bench at the end of 1913. (Kt. Bach., 1908; K.C.M.G., 1914.)

Parkes, SIR HENRY (1815-1896), born at Stoneleigh in Warwickshire, England, on 27 May 1815, was put to work at the age of eight in the neighbourhood of Gloucester and was subsequently apprenticed to the ivory-turning trade in Birmingham. There for eight years he was an active member of the Birmingham Political Union, which vehemently supported the Reform Bill of 1831 and afterwards developed along Chartist lines; he wrote for *The Chartist* both prose and verse, and spent his Sundays teaching at Yardley Sunday-school—Sunday-schools in those days taking on themselves a good deal of secular instruction as well. The main currents of his life were thus already determined when in 1839 he and his wife migrated as 'bounty emigrants' to New South Wales in the ship *Strathfieldsaye*, which reached Port Jackson on 25 July. After working for a few months as an agricultural labourer on Sir John Jamison's estate near Penrith, Parkes returned to Sydney, tried various occupations (including that of a customs official), and then set up in business for himself as an ivory-turner and toy-dealer. His advanced political opinions brought him into contact with local democrats, and in 1848 he was appointed one of two secretaries for Robert Lowe's political campaign (see SHERBROOKE, LORD); he also took a prominent part in the anti-transportation movement. In December 1850 he established the *Empire* newspaper, of which he remained proprietor and editor until 1858; during the early fifties it was a powerful democratic organ, and in 1854-6 led a strong attack upon what he considered reactionary clauses in Wentworth's constitution

bill. In May 1854 he was returned by the Sydney electors to the legislative council, retained his seat when responsible government was established, but resigned in 1857 owing to the financial failure of the *Empire*; this loss was remedied by sympathizers, and Parkes successfully contested the elections of 1858, but before the end of the year was brought into the insolvency court, terminated his connection with the *Empire*, and resigned from the assembly.

His journalistic work being thus at an end, he was able to devote more time to politics, and in June 1859 was returned at the top of the poll for East Sydney, but resigned his seat in May 1861 on appointment as one of two emigration commissioners to Great Britain; his task was to stimulate the interest of small agricultural capitalists in Robertson's land scheme of selection before survey (see LAND SETTLEMENT and MIGRATION). After a not very profitable 14-months' tour of the northern and midland counties Parkes returned to Sydney, in 1864 was sent to the legislative assembly by Kiama, and in 1866 entered the Martin ministry as colonial secretary. His first important measure was a public schools act which set up a council of education (*a*) to distribute the state subsidy to denominational schools and (*b*) to establish state schools of a non-sectarian character (see EDUCATION, PUBLIC). He was also responsible for the hospitals act of 1866 (which provided for the inspection of hospitals) and arranged with Florence Nightingale to send to the colony a number of trained nurses (see HOSPITALS). In 1867 was passed a municipalities act, the principle of which was not modified until 1905 (see LOCAL GOVERNMENT). During the same year he introduced a bill for volunteer enrolment, a subject in which he had been interested since 1859 (see MILITARY DEFENCE). As ministerial head of the police force he was involved in the sectarian controversy stirred up by O'Farrell's attack on the Duke of Edinburgh, and in September 1868 resigned from the ministry. In 1870 he resigned his seat because of financial difficulties, but was back in parliament in 1872, and in May of that year was commissioned to form his first ministry, which lasted until February 1875. His term of office was not marked by any outstanding achievement; he came into conflict with the legislative council in connection with an electoral reform bill which had to be laid aside; passed a prisons regulation act; and abolished the *ad valorem* customs duties imposed by his predecessors. He also arranged with the governments of Victoria and South Australia to suspend the collection of intercolonial duties for three years—an arrangement which Victoria ceased to honour before the expiry of that period. Towards the end of 1874 his ministry was defeated on a question of the governor's prerogative to pardon Frank Gardiner (q.v.); this was followed by a dissolution, and by a ministerial defeat early in the new session.

In his next premiership (March-August 1877) Parkes accomplished nothing, owing to the confused state of party politics, but in December 1878 he formed a third ministry in association with his old antagonist John Robertson (q.v.). His first important measure was an education act which extended the principle of secular education adopted in 1867, placed the state-school system under the control of a responsible minister, and abolished the subsidy to denominational schools; this measure was bitterly opposed by the clergy, especially by those of the Roman Catholic Church. At an intercolonial conference held in December 1880-January 1881 to discuss a uniform tariff, Parkes carried a resolution affirming the desirability of creating a federal council, but only three colonies voted for the bill by which it would have been formed, and the proposal was dropped. Almost at once ill-health forced Parkes to take a holiday overseas, and on 29 December 1881 he left Sydney for what became a triumphal progress through the United States, Canada, and England. Returning towards the end of 1882, he found the ministry divided, was defeated at the polls, and retired from office on 4 January 1883; in 1883-4 he revisited England (thus missing the intercolonial conference which did create the federal council), and on his return to New South Wales resigned his seat after two months' attendance in parliament, and announced his definite retirement from public life.

A few months later the despatch of the Sudan Contingent (q.v.) in February 1885 brought him back to the political arena. He savagely denounced Dalley's action, returned to parliament as member for Argyle, and was on Alexander Stuart's motion rebuked for having grossly libelled the legislative assembly; but Stuart, though premier, thought better of his original proposal to expel the offender. Almost immediately John Robertson's death left Parkes leader of the opposition, and the protectionist proposals of G. R. Dibbs, Stuart's treasurer, gave him a good election cry; in January 1887, at the age of 71, he swept the polls, and formed what was probably the soundest and most notable ministry of his career, with William McMillan as treasurer and J. H. Carruthers as minister for education. Besides restoring the freetrade character of the tariff, he created the standing committee on public works and the independent board of railway commissioners, concluded and financed the naval agreement made at the colonial conference of 1887 (see NAVAL DEFENCE), and yielded to public pressure over the Chinese issue of 1888 (see IMMIGRATION RESTRICTION). In January 1889 he was temporarily ousted from office, but again defeated Dibbs on the fiscal issue and formed his fifth and last ministry on 8 March.

The rest of his life was devoted to the cause of federation. The federal council was, in his opinion, an inadequate instrument of Australian progress: nothing short of a federal parliament would achieve the end 'One People, One Destiny.' When Major-general Edwards, a British officer brought to Australia to report on military defence (q.v.), recommended the federalization of colonial troops, Parkes seized the opportunity to appeal for political union on a federal basis. His Tenterfield speech of 24 October 1889 brought about a premiers' conference in February 1890 and the calling of a national convention to draft a federal constitution. Parkes was at his best in dealing with a subject that fired the imagination and gave scope for eloquence, and it was expected that he would win over the New South Wales parliament as he had won over the conference of premiers to the federal cause; but before the debates on federation were concluded he met with a serious accident, underwent weeks of enforced absence from the assembly, and on his return found that his personal influence had been undermined. Nevertheless the convention met in Sydney in March-April 1891 under his presidency, and drafted a constitution bill for submission to the parliaments. The attitude of New South Wales

was all-important, for federation was bound up with the fiscal issue. Parkes, despite his free-trade views, put federation first; George Reid (q.v.), an able and a younger man, subordinated federation to freetrade. Nevertheless Parkes with the help of the federal protectionists was able to defeat a hostile resolution by Reid, and the way seemed open for him to bring in the constitution bill. Instead of doing this, however, he gave preference on the notice-paper to local measures—an act which his friends criticized as an error of judgment. After the 1891 elections he retained office only by the support of the new Labour party, and this was withdrawn in October. Parkes resigned office, and was ousted from his position as leader of the free-traders by Reid, whom he detested. He was now an old man, and his mind became warped by personal rivalry. When the Dibbs ministry was defeated in 1894, Reid, not Parkes, was sent for; Parkes was bitterly disappointed, and on 16 May 1895 made known his readiness to coalesce with the protectionists by moving a vote of censure on the Reid government. At the following elections he opposed Reid in the King division, but had lost public sympathy, and was not returned; in February 1896 he made another unsuccessful attempt to obtain a seat at Waverley; on 27 April he died.

Few Australian politicians have so often changed their constituency. To note the changes as they occurred would have interrupted too much the above record of Parkes's political services, and they are therefore given here. He sat for Sydney City (1856), Cumberland North Riding (1858), East Sydney (1859-61), Kiama (1864-9), East Sydney again (1869-70), Kiama again (1869-70), Mudgee (1872), East Sydney again (1872-7), Canterbury (1877-8), East Sydney for the fourth time (1880-2), Tenterfield (1882-4), Argyle (1885), and St. Leonard's (1885-95). In 1869 he was elected by East Sydney and Kiama, but resigned the East Sydney seat in February and the Kiama seat in December. This political inconstancy stamps him as what would nowadays be called a 'temperamental' statesman; but it was this very temperamentalism that helped to make him the great statesman he was—probably the greatest Australia has known. It gave him the intellectual greed that absorbed new ideas and inchoate reforms from all quarters, the zeal that enabled him to carry through the reforms and impress the ideas on the public, the invincible pride that refused to acknowledge defeats, however severe; it made him to the end of his life a force that might be regarded with various emotions (all strong) but could never be neglected. He was, moreover, one of the very few Australian statesmen who knew enough about European politics to see Australia 'to scale,' so to speak—not disproportionately large against a diminished world; for that reason he could meet British statesmen as an equal, and could insist on compliance with Australian desires—as he did during the Chinese immigration troubles of 1888—without appearing (as did several of his contemporaries) merely a petulant schoolboy.

Parkes never lost his early interest in literature. He was always generous to struggling artists and writers (e.g. Henry Kendall), and himself published in 1857, 1885, 1889, and 1895 small volumes of indifferent verse, and in 1892 *Fifty Years in the Making of Australian History*, a two-volume record of his political experiences. A posthumous volume, *An Emigrant's Home Letters*, written to his sister in 1838-43, was published by his daughter in 1896. (K.C.M.G., 1877; G.C.M.G., 1888.)

See Charles Lyne's *Life of Sir Henry Parkes.*

Parkinson, SYDNEY (1745?-1771), born in Edinburgh about 1745, was apprenticed to a woollen-draper, but, finding art more congenial, went to London and was engaged by Sir Joseph Banks to make drawings of a collection of figures and specimens of animals brought from India. In 1768 Banks selected him as natural history draughtsman on the scientific staff of the *Endeavour*; he made 955 drawings (of which 675 were only sketches) during the voyage, and kept an interesting journal, but on 26 January 1771, soon after leaving Batavia, died of a fever which had attacked most of the ship's company in that port. When the *Endeavour* returned to England Parkinson's brother Stanfield claimed his papers and some of his drawings under the terms of his will; Banks thereupon bought the papers from the brother and sold them to Hawkesworth, who used them in compiling the official *Journal*. Stanfield, however, had transcribed the papers and endeavoured to publish them; but Hawkesworth obtained an injunction that delayed publication until after the appearance of his own book. The *Journal of a Voyage to the South Seas in H.M.S. Endeavour,* edited by Stanfield Parkinson, appeared in 1773.

Parliamentary Elections. The use of the ballot (q.v.) is universal in Australia; but only the State of South Australia retains the antiquated system of electing members by a simple majority. The Commonwealth has adopted preferential voting for both the senate and the house of representatives; Tasmania has a system of modified proportional representation; Victoria and Western Australia have preferential systems; Queensland has a system of contingent voting; New South Wales, after a trial of proportional representation for several years, has reverted to a single-seats, 'first-past-the-post' system, but gives the elector the option of exercising a preferential vote.

Commonwealth.—Each of the 75 members of the house of representatives sits for a separate constituency. An elector must vote for all candidates in his constituency, marking their names 1, 2, 3, etc., in the order of his preference. On the first count only No. 1 preferences are counted; if one candidate secures an absolute majority of these, he is elected. If no one has an absolute majority, the candidate with the fewest votes is excluded, and the No. 2 preferences on his papers are distributed to the candidates for whom they were recorded. This process is continued till one candidate has a majority over all the other candidates left in the count. Thus, if there are three candidates, and on the first count Smith has 9000 votes, Jones 7000, and Robinson 5000, Robinson is excluded. If of his second preferences 4000 go to Jones and 1000 to Smith, Jones is declared elected.

For the senate each of the six States is a single constituency represented by six members who are elected for a term of six years, but except in the contingency mentioned below only three of them retire at a time, so that at normal elections each State returns three senators. Should, however, a senator die or resign during his term, the vacancy is filled by the State legislature (both houses sitting together, except in the case of Queensland, which has no 'upper' house); but the substitute holds the position only for (*a*) the remainder of the original

member's term, (*b*) until the next normal election for the senate, (*c*) until a 'double dissolution' takes place (see CONSTITUTIONS). In such cases there will be not three but four seats to fill. Of course if more than one senator dies or resigns the number to be elected is correspondingly increased.

The mechanism of senatorial elections is complicated. The minimum number of candidates for whom the elector must vote is double the number of seats to be filled, with one added (for instance 3+3+1=7); if there are not enough candidates to allow of that being done, the elector must vote for every name on the ballot paper; but if there are more candidates than double the number of seats plus one, the elector need not vote for those which are in excess, unless he chooses; in all cases the names voted for must be marked in order of preference. If candidates prefer to group themselves on party lines, their names are printed on the ballot-papers in alphabetical order within the group, and the names of independent candidates (i.e. those who do not belong to a group) are printed in alphabetical order after the group or groups. The order in which the groups are placed is decided by the initials of the candidates' surnames in a fashion more easily illustrated than described. Thus, let A, C, G, L, P, S, and W be the initials of the surnames of seven candidates, of whom A, L, and S belong to one party, C, P, and W to the other, G being an independent candidate. A, L, and S are the 1st, 12th, and 19th letters of the alphabet, totalling 32; C, P, and W total 42; therefore the order on the ballot-paper will be A, L, S (in a group), C, P, W (in a group), G.

The quota (i.e. the number of votes required to elect a candidate) is one more than half the total number of valid votes cast; thus, if 600,000 votes are cast in a State, the quota is 300,001. Any candidate who on the first count has the quota (that is an absolute majority of first-preference votes) is elected. If no candidate has reached the quota, the one who has polled the fewest votes is temporarily excluded, and the second preferences on his ballot-papers are transferred to the other candidates in accordance with the wishes of the electors; this exclusion of candidates successively at the bottom of the poll is continued until some one candidate attains the quota (in this example 300,001), and is elected. The whole process then begins again. The excluded candidate's ballot-papers are brought back, the second preferences on those of the elected senator are distributed as indicated, and again the lowest candidate is temporarily excluded. The process is repeated as many times as is necessary, until the requisite number of candidates have reached the quota. A little thought will show that under this system the group that secures a majority of 'first preference' votes must win all the seats, provided the voting has been on strict party lines. Those who devised the system for the senate possibly hoped that the members of what they intended to be the States House (see CONSTITUTIONS) would represent not a party but the State.

To elucidate the system further an official example of its working is here given. In an election for a three-member constituency 100 first-preference votes are divided among nine candidates as follows:—Absalom 13, Johnson 25, Jones 11, Keith 12, Knight 8, Robinson 10, Smith 8, Swanson 7, Western 6. No candidate has an absolute majority (i.e. 51 or more), so on the second count Western is excluded and the second preferences on his 6 papers are transferred to their candidates. When this has been done Absalom has 15, Jones and Keith 13 each, and Robinson 11. Next Swanson is excluded, and his 7 votes transferred, making Robinson 17 and Knight 9; then Smith, whose votes bring Johnson to 28 and Keith to 18. Knight's papers (including the one transferred to him from Swanson, which goes to the candidate who is marked third on it) are then dealt with. This gives Absalom 20, Jones 15, and Robinson 19. On the sixth count Jones is excluded, and his 15 papers (including the two from Western and two from Knight) dealt with; all go to Absalom, and bring him to 35. Keith is excluded on the seventh count. His 18 papers (including one from Western and five from Smith) all go to Johnson, making him 46. Robinson, with 19 votes, is excluded on the eighth count; of his 19 papers (including one from Western, six from Swanson, and two from Knight) 18 go to Absalom—one is set aside because no preference for either Absalom or Johnson (the two continuing candidates) is recorded on it. Absalom has now 53 votes—an absolute majority—and is elected.

In filling the second vacancy all the candidates except Absalom are restored to their original position and start afresh. Absalom's 13 first preferences are then distributed to the candidates to whom their second preference has been given, and the other processes of exclusion and distribution are carried out as before, until on the seventh count Jones has 54 votes, and is elected to fill the second vacancy. For the third vacancy all the candidates are restored except Absalom and Jones. Their votes are assigned to the continuing candidate next in order of preference; thus, if a paper is marked Absalom 1, Jones 2, Knight 3, it is now counted to Knight. A repetition of the processes of exclusion and distribution results in the election of Knight with 54 votes.

From the way in which the votes are transferred it is obvious that Absalom, Jones, Knight, Robinson, Swanson, and Western form one party group and Johnson, Keith, and Smith another. Though the second group has 45 first preferences against the first's 55, it does not win a single seat. And, provided there were no cross-voting, it would not win one if the figures were 49 to 51. Though no such case has been recorded, it would be quite possible for a candidate who did not receive a single first preference to be elected to the senate if his party had the majority of first preferences and the ballot papers had been marked on strictly party lines.

Following the example of Queensland, the Commonwealth adopted compulsory voting for both the senate and the house of representatives at the elections of November 1925, a penalty of £2 being imposed on enrolled persons who without sufficient reason did not record a vote. This drastic law was effective. The percentage of voters to electors enrolled was 91.31 (males 91.62, females 90.99); the effective percentage was somewhat higher, since the number of names on the roll is always slightly in excess of the actual number of electors. The proportion was highest in Barton (New South Wales) where it was 95.37, and lowest in Kennedy (Queensland) where it was 83.4. At previous elections the percentage varied between 77.69 and 53.04 for the senate, and between 78.3 and 55.69 for the house of representatives.

New South Wales.—Starting with 54 members, elected in 32 districts, the New South Wales legislative assembly grew till in 1894 there were 74 electorates and 141 members. This was the highest number reached, and in 1904, as the result of a referendum following upon federation, the number of members was reduced to 90. In 1918 a system of proportional representation voting was adopted, under which the 90 members were elected by 24 electoral districts. Eight electorates in the metropolitan area, and the city of Newcastle, were represented by five members each; 15 electorates returned three members each. A modification of the system was carried in 1922, the elector being required to record preferences only to the extent of the number of candidates to be elected. In 1926, after a contest with the legislative council in which it sought to secure the adoption of an unqualified 'first-past-the-post' single-seats system, the government accepted a compromise, which, while it provides for the abandonment of proportional representation and a redistribution of the electorates into single seats, permits the elector, if he so desires, to exercise a preferential vote, though a single vote is all that is strictly necessary. The number of members remains at 90. Chief among the objections made to proportional representation were that the electorates became too large, that undesirable rivalry and duplication of effort on the part of members for the same electorate resulted, and that the system failed to provide a satisfactory working majority for whatever government gained office.

Members of the legislative council are nominated to their position by the State governor on the advice of his ministry. The number of councillors varies; for many years it has been roughly two-thirds of the number sitting in the assembly, but in 1921 it was brought up to 75 and in 1925 to 99, although the legislative assembly has only 90.

Casual Vacancies.—In 1920 provision was made that any casual vacancy in the New South Wales legislative assembly should be filled by the candidate for the same constituencies at the last election who, while unsuccessful, represented the same party interest as the late member, and who, upon the count of the primary preference votes then polled, was highest on the list in respect of such votes for unsuccessful candidates representing that party interest, provided that he was willing to be elected, and available to fill the vacancy. In determining what party interest had been represented by the late member, the clerk of the assembly was to have regard to his vote or votes on any motion or motions of censure during the existing parliament. This last-mentioned provision was called into use in July 1926, when A. D. Kay, a member for North Shore, who was elected as an Independent, was appointed by the Labour government to a position on the meat board. On the ground that Kay had voted with the government on a censure motion, an unsuccessful candidate—A. Tonge—was nominated by the government for Kay's seat, although he had polled 3995 votes less than the quota necessary for election. The circumstances caused a heated controversy, and it was urged that, to have maintained consistency with the principles of proportional representation, provision should have been made to continue the count and distribution of preferences cast at the general election. The 1926 act, abolishing proportional representation, provided that the casual vacancies provision should carry on for the life of the then existing parliament.

L.G.W.

Victoria.—For the legislative assembly this State is divided into 65 one-member electorates. Since 1911 a system of preferential voting has been in use, electors voting for all candidates in order of preference by placing numbers before their names on the ballot-paper. The candidate with an absolute majority of first preferences is elected; if no candidate has such a majority, the candidate lowest on the first count is excluded and his second preferences are distributed, and this process is repeated until one candidate obtains an absolute majority. Should two candidates obtain the same number of votes, the returning officer's choice is elected.

For legislative council elections the State is divided into 17 provinces, each returning two members; the tenure is for six years, and one member retires every third year, the method of election being the same as for the assembly. In case of a dissolution, when both members retire, the elector must strike out the names of the candidates for whom he does not intend to vote. The two candidates with the highest number of votes are then elected, the method being 'first past the post.'

Queensland.—Voting on a modified system of optional preferential voting is compulsory. The elector has to strike out the names of the candidates for whom he does not intend to vote, and may then, if he likes, indicate by figures his preferences among the rest. If in a one-member constituency no candidate receives an absolute majority, all except the two highest are declared defeated. Votes given to defeated candidates are then allotted to the two still in the running according to such preferences as the voter may have declared. Where two members are to be returned, and there are not more than four candidates, the two highest on the first count are declared elected. If there are more than four candidates, and none has an absolute majority, all except the four highest are defeated, their votes are distributed as in the one-member case, and the two candidates then ahead are elected. If one candidate receives an absolute majority of votes, he is elected and all except the two nearest to him are defeated. Distribution then follows until one of the two is elected.

Queensland has no second chamber. See QUEENSLAND.

South Australia.—This State has eight districts returning three members each to the house of assembly, and eleven returning two each. Electors may vote for one candidate only, or for the full number to be elected. The method of voting is to place a cross opposite the elector's choice. There is no transfer of votes.

There are five legislative council districts, each returning four members. The voting system is the same as for the assembly.

Western Australia.—Preferential voting, which had previously been optional, was made compulsory in Western Australia in 1911. There are 50 single electorates for the legislative assembly. The elector has to indicate his first preference by the number 1 and to give contingent votes for all the others, in order of preference, if there are more than two. If he marks all but one, it is held that the next number is intended to be placed opposite the name of the remaining candidate, and the vote is valid; it is also valid if the first preference is indicated by a cross instead of by the figure 1.

If a candidate has a majority of first prefer-

ences, he or she is declared elected. Otherwise the candidate with the fewest first preferences is excluded and his votes are distributed among the other candidates, this process being continued until one candidate has an absolute majority. If there are two candidates left in and neither has an absolute majority, the one with most votes is elected.

For the legislative council the State is divided into ten provinces, each returning three members.

Tasmania.—This State is divided into five constituencies for federal elections; these are used for State elections also, each returning six members to the house of assembly under the Hare-Clark system of proportional representation. The elector must place opposite the names of three candidates the numbers 1, 2, 3, in order of choice. He may show as many more preferences as he pleases. The returning officer counts the number of first choices, and fixes a quota by dividing the number of valid ballot-papers by seven (one more than the number of members to be elected) and then adding one to the quotient (thus, if there are 14,000 valid papers, the quota is 2001). Any candidate who on the first count secures or exceeds the quota is elected. If he exceeds the quota, his surplus is divided by the quota to find the transfer-value (thus, if the quota is 2001 and the surplus 667, the transfer-value is one-third). The number of second choices for each unelected candidate is then multiplied by the transfer-value and the result (disregarding fractions) is added to the number of first choices for that candidate. When by this process the number of a candidate's votes is raised to, or above, the quota he is elected.

If the transfer of votes does not result in the election of the required number of candidates, the lowest candidate is excluded and his votes are transferred to the candidates next in order of preference on his papers. The process of exclusion and transfer is continued until all but six candidates have been excluded, and these six are then elected. In determining which candidates are next in order of preference any candidate who has been elected or excluded is not considered, and the next candidate is taken. In a by-election, when one candidate only is to be elected, the lowest is excluded unless one candidate has secured a majority of the formal votes. Each vote given to him is (unless it is exhausted) transferred to the candidate next in order of preference. If no candidate then has an absolute majority of votes, the process is continued until one has an absolute majority. If on the final count two candidates have an equal number of votes, the returning officer decides which is to be elected. The working out of the results of a Tasmanian election involves elaborate mathematical work on the part of the returning officers and their staffs, but all the electors have to do is to put numbers opposite the names of the candidates in the order of preference.

For the legislative council there are 13 country divisions returning one member each, the Hobart division returning three members, and the Launceston division returning two members.

T.D.

Proxy-voting in parliament.—In every parliament in the British Empire there has developed a system known as 'pairing,' by which two members on opposite sides may agree to absent themselves from the house at the same time, the loss of one vote thus compensating for the loss of the other. The refusal by the opposition in the Queensland parliament in 1922 to grant 'pairs' to members of the government party brought about the passing of an act allowing members in certain circumstances to vote by proxy. This was the first application of such a practice in any popularly elected house in the Empire, although for some years until 1867 it had been permitted to peers in the house of lords—a precedent upon which the Theodore government based the innovation. The government had a majority of only one vote at a time when the fiercest political animosity prevailed, and the opposition refused to grant a 'pair' to William McCormack (afterwards premier). For this reason on 16 August 1922 E. G. Theodore introduced the legislative assembly act amendment bill, 'making provision in certain cases for voting by proxy of members of the legislative assembly, absent through ill-health.' The bill was fiercely contested, but was carried through its various stages on the casting-vote of the speaker or the chairman of committees, and received assent on 22 August. It enabled members to make application, accompanied by a medical certificate, to the speaker to have their votes recorded by proxy. The principal argument advanced by the government was that the opposition, by refusing 'pairs,' was seeking to deprive constituencies of their right to be represented. On the other hand, the opposition contended that both custom and the constitution required a member to record his vote personally. On the afternoon that the speaker received the governor's assent to the bill four government members (including McCormack) were ill, and Theodore, having presented the necessary medical certificates, claimed proxies for them. During that session he exercised the right on 35 occasions. A few months later a general election gave him a working majority, and the practice was discontinued, though the act still remains capable of full application.

Parrakeets. See PARROTS.

Parramatta, a town of about 15,000 inhabitants (census of 1921), distant from Sydney 18 miles by water, 15 by road, and 14½ by rail, lies astride a little creek which—because the tidal estuary into which it flows is of considerable size—is called the Parramatta River.

In April 1788 Phillip, convinced that no settlement on Botany Bay or Port Jackson could ever become self-supporting in food-supplies, discovered just above the head of navigation on the Parramatta estuary an area much more suitable for agriculture. Here on 2 November he planted a settlement which he named Rose Hill after George Rose, a secretary of the British treasury and friend of William Pitt the younger, who afterwards held minor political offices under Pitt, Portland, and Perceval. Phillip thought—and Dundas agreed with him—that this area should have been the site of the first settlement. By 1790 about 40 acres had been cleared, and most of it laid down in maize; potatoes failed, but cabbages, melons, and pumpkins throve 'astonishingly,' a cabbage cut for the King's birthday in 1789 weighing 27 lb. The first grapes grown in Australia were cut in the garden of the governor's house on 24

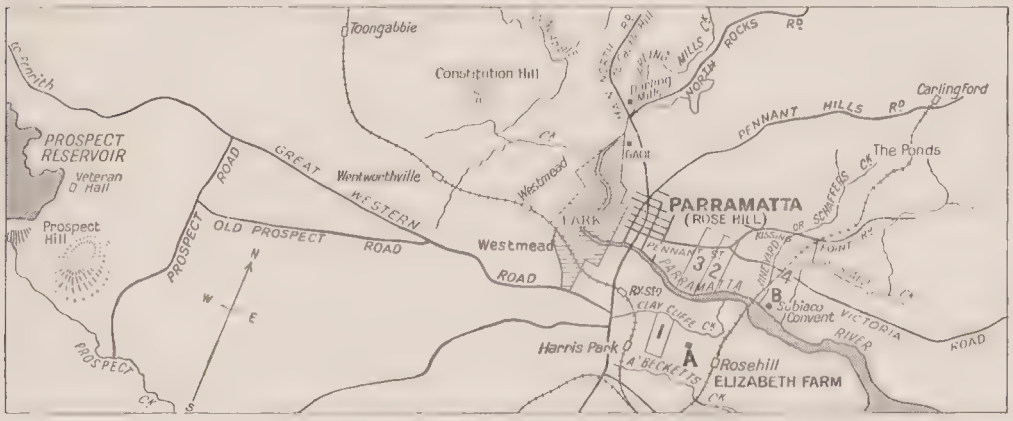
6. Groper (female) (*A. gouldii*). One-eighth natural size.
7. Blue-spotted Groper (*Choerodon venustus*). One-sixth natural size.
8. Rock Whiting (*Neoodax semifasciatus*). One-fifth natural size.

January 1791. On 4 June of that year the name of the settlement was altered to Parramatta, the name Rose Hill being reserved for the small hill (now in Parramatta Park) on which Phillip's house stood. At that moment Parramatta was all but the capital; 'Sydney,' wrote Tench, 'has long been considered as only a depot for stores, it exhibits nothing but a few old scattered huts and some sterile gardens, cultivation of the ground is abandoned, and all our strength transferred to Rose Hill.' There the majority of the convicts were stationed, and all the artificers were employed in building huts; the streets were planned 200 feet wide, the principal street a mile long; a church, barracks, a hospital, and residences for all the principal officials were in course of erection. But Hunter, though no farmer, had already noted that the soil, though better than any nearer the sea, was merely a thin layer of humus on a deep bed of sand, and would require 'much manure, much dressing, and good farmers to manage it, before good crops can be expected from it.' Writing in October 1792, George Thompson described the settlements thus:—

> Sydney is the spot where the first settlement was formed, merely for the advantage of good water and the conveniency of the harbour. In this part are only gardens sufficient to supply the inhabitants with vegetables, etc. . . . . Parramatta is the grand settlement.

At that time it had 1970 inhabitants against Sydney's 1170, but thenceforth began to lose ground; the foundations intended for the church became those of a gaol, which in a short time was transformed to a granary. Two factors decided the rivalry. To Parramatta all imported goods must be brought by water up a shallow tidal estuary, so that Sydney must remain the port of discharge for oversea vessels; moreover, as soon as the Hawkesbury lands were opened up, Parramatta fell into the background as a food-supplying area—and there seemed no reason for interposing between the farm-lands and the port a capital that could neither grow wheat nor accommodate shipping.



PARRAMATTA DISTRICT.

A. John Macarthur's Home. **B.** Hannibal Macarthur's Home (now Subiaco Convent). Grants to first rural settlers (30 March 1791) shown thus:—1, James Ruse (30 acres); 2, Robert Webb (60 ac.); 3, William Reid (60 ac.); 4, Phillip Schaffer (140 ac.).

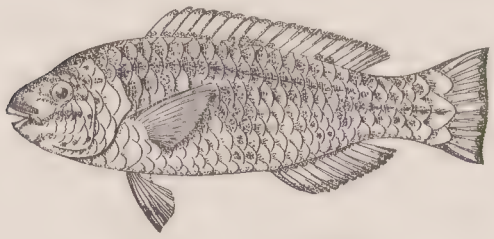
Still, Parramatta had its attractions. Among its early settlers are counted James Ruse (q.v.), who put in the first wheat crop; Phillip Schaffer, the first free immigrant settler; William Batman, father of John Batman; and John Macarthur, the inventor (one might almost say) of the Australian merino sheep. Round it spread the smaller farm-settlements, Toongabbie and Castle Hill and Newington and the Field of Mars. In 1796 the town was organized into police divisions, and all the houses were numbered. In 1803 a coach-service to Sydney was established and a water-mill erected on the creek. St. John's church, the first (except Johnson's wattle-and-dab structure, for which see CHURCH OF ENGLAND) in Australia, was of slow growth; its foundations were laid on 5 April 1797, it was opened for service (without pews) on 10 April 1803, completed about 1808, and furnished with twin towers in 1815-16. These towers were added at the request of Governor Macquarie's wife, whose last sight of England had included the twin towers of the Saxon church at Reculver in Kent. In 1852 the church building was taken down and a new church built on to the old towers. Macquarie added to the public buildings a female orphan school and a new hospital, besides rebuilding government house; Brisbane, who spent at Parramatta as much of his time as possible, on 1 May 1822 opened an observatory in the park (see ASTRONOMY). In 1838 the town boundaries were delimited by David Lennox and in 1839 marked with inscribed stones.

As settlement spread—and especially when it crossed the Blue Mountains westwards and occupied the Hunter River valley to the north—the agricultural importance of Parramatta dwindled, and it became merely the centre of a small farming and fruit-growing district; but it retained social importance as the country seat of the governor. On 7 December 1847, however, a carriage accident in the park killed the wife of Governor FitzRoy and crippled the governor himself; from that time the Parramatta government house fell out of favour, and in the end became a private boarding-house. It is now occupied by The King's School. The town served as the temporary terminus of the first New South Wales railway in 1855, and was incorporated in 1861.

The name Parramatta is usually said to be an aboriginal word meaning 'Eels sit down,' and eels are still abundant in the creek. Elizabeth Macarthur, however, writing in 1795, said the name meant 'head of a river.'

Parrot-fishes. This name is commonly applied to a large number of brightly-coloured fishes belonging to several allied families. The true parrot-fishes of the family Scaridae are characterized by the possession of beak-like

jaws, with which they break off pieces of living coral to obtain the polyps and worms within it. The throat is provided with remarkable teeth that coalesce to form grinding-plates, between



Callyodon pyrrhostethus.

which the coral is triturated before being swallowed. All true parrot-fishes are inhabitants of tropical waters, and a number occur in the warmer waters of Australia. It is probable that many of the so-called species are merely sexual forms, the males differing from the females in marking and colouring; the young also differ from adults. Parrot-fishes are common in the neighbourhood of coral-reefs and, when fully grown, are usually so gorgeously coloured as to vie with any other form of life, terrestrial or marine. See WRASSES.

In southern Australian waters the Scaridae are replaced by fishes of an allied family (Neoodacidae) which also have teeth that coalesce into beak-like structures. They include the rock whitings (*Neoodax*, shown on plate XXXV, fig. 8) and the herring cale (*Olisthops*)—both inaptly named, as the fishes have no affinity with either whitings or herrings. The herring cale is strangely variable in colour, the male being usually bluish-black with blue stripes on the fins, and the female greenish mottled with orange; but these colours are sometimes reversed in the sexes. The Rainbow-fish (*Heteroscarus filamentosus*) is another brilliantly-coloured representative of the family, and, together with its allies, is captured near rocky reefs on the coasts of the southern half of Australia; its beak-like teeth distinguish it from a wrasse, which is also known as rainbow-fish or maori.

A.R.McC.

Parrots, birds of the order Psittaciformes, as a rule brilliantly coloured, possessing very stout hooked beaks, and feet with two toes turned forward and two backward—usually noisy, associating in flocks, and nesting in holes in trees. Many in captivity can be taught to whistle tunes, but few Australian parrots—as distinct from cockatoos—learn to talk. All parrots lay white eggs, and feed their young by regurgitating partly digested food. They occur in Central and South America, tropical Africa and southern Asia, and throughout the Australian region, being more numerous in our region than in any other, and presenting greater diversity of form. Australia and Tasmania possess 46 species; as several of these have been discovered in comparatively recent years it is not improbable that still others remain unknown. Their classification is a matter on which there is considerable difference of opinion. The Australian forms have recently been placed in seven families, which present fairly distinct characters, and these will be adopted here. Cockatoos are dealt with in a separate article.

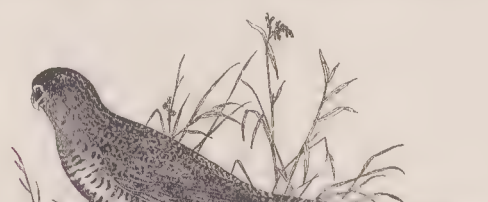
The lorikeets (Trichoglossidae) are mostly small parrots, peculiar to Australia and the Malay Archipelago, characterized by their brush-like tongues, by the aid of which they extract honey from flowers and pulp from juicy fruits. They are very noisy birds, travelling swiftly in small parties, screaming as they fly, and assembling in large numbers wherever many honey-bearing trees (such as eucalypts, banksias or bottle-brushes) are in flower. The best-known and most gaudy of the seven Australian species, generally called Blue Mountain Parrot (*Trichoglossus moluccanus*) is plentiful throughout eastern Australia from Cape York to Tasmania. The Musk Lorikeet (*Glossopsitta concinna*), a smaller bird, is remarkable for its musky smell. The Purple-crowned Lorikeet (*Glossopsitta porphyrocephala*) is the only member of the family that has reached south-western Australia, in spite of the abundance of honey-making plants in that region.

The fig-parrots or lorilets (Opopsittidae) are small birds characteristic of the Papuan region. Two species are found in Queensland, but they frequent jungles and are very little known.

The Cockatoo-parrot or Quarrion (*Leptolophus hollandicus*), known to bird-fanciers as the cockatiel, is the sole member of the family Leptolophidae. It is common in the inland areas of the continent, feeding largely on the seeds of grasses and herbage. As it possesses a crest, the cockatiel has been regarded as a relative of the cockatoos, but it is probably more nearly related to the parrakeets.

Until 1913 it was not known that the true parrots (Loriidae), large stout birds with comparatively short tails, were represented in the Australian fauna. In that year, however, Dr. W. MacGillivray obtained on the Pascoe River in northern Queensland specimens of two large parrots previously known only from New Guinea. One of these, the Red-sided Parrot (*Lorius pectoralis*), is remarkable for the great difference in the coloration of the sexes, the male being chiefly green and the female bright blue and red.

The family Polytelidae contains five moderately large species of long-tailed parrakeets—about 16 inches in length—of which the best-known is the gaudy King Parrot (*Aprosmictus scapulatus*) of eastern Australia. The delicately tinted Alexandra Parrot (*Polytelis alexandrae*), another member of this family, is an inhabitant of the most arid portions of the continent, its range extending from the Macdonnell Ranges



Ground Parrot (*length* 13 *in.*).

in central Australia westwards to the East Murchison goldfields of Western Australia, north-west nearly to the Fitzroy River.

The great majority of Australian parrots be-

long to the family Platycercidae, the broad-tailed parrakeets. The most familiar broad-tails are the Rosella (*Platycercus eximius*) of south-eastern Australia and Tasmania, the name of which is derived from Rose Hill, near Sydney, where it was first observed; the so-called Crimson Lowry or Pennant Parrakeet (*P. elegans*) of eastern Australia; the Adelaide Rosella (*P. adelaidae*), of the Mount Lofty ranges in South Australia; the Mallee Parrot or Buln-buln (*Barnardius barnardi*) of the interior of eastern Australia; the Port Lincoln Parrot (*B. zonarius*) of South and Western Australia; and the Twenty-eight (*B. semitorquatus*) of the south-west, whose name is derived from its note. These are the species commonest in southern Australia, and most often seen in captivity. To this family belong also the grass-parrakeets (*Neophema*), which are largely terrestrial in their habits, feeding chiefly on grass-seeds. One of them, the Rock Parrakeet (*N. petrophila*), nests in holes in the cliffs of islands off the coasts of South and Western Australia, sometimes visiting the mainland to feed. Several members of the family have become almost or quite extinct since the settlement of Australia.

The ground parrakeets (Pezoporidae), peculiar to Australia, comprise three species, the best-known being the Budgerigar or Shell Parrot (*Melopsittacus undulatus*), very abundant throughout the interior and a familiar bird in aviaries throughout the world. The Ground Parrot (*Pezoporus wallicus*) inhabits open heathy country near the sea along the southern coasts of Australia and in Tasmania. It is completely terrestrial in habits, running swiftly on the ground, never even perching in a tree, and laying eggs in a hollow among the herbage. It appears to be rapidly approaching extinction. Its congener, the Spinifex or Night Parrot (*Geopsittacus occidentalis*), is apparently now extinct. It formerly occurred in spinifex country in central and western Australia, and is said to have been nocturnal in its habits and completely terrestrial. Considering the unaltered character of its habitat and the great area over which it was formerly found, its extinction is not easily accounted for, and cannot be attributed to human agency—unless it has been caused by the introduction of cats, which have penetrated into regions beyond human settlement.

W.B.A.

Parry, Henry Hutton (1827-1893), son of Thomas Parry, bishop of Barbados in 1842-69, was born in 1827, educated at Rugby school and Balliol College, Oxford (B.A., 1851; M.A., 1858), ordained deacon in 1851 and priest next year. Under his father he did parochial work until 1855, was tutor at the local theological college till 1860, and then became archdeacon of Barbados (1861) and coadjutor-bishop (1868). In 1876 he was given a doctorate by the university of Durham, and was appointed to the see of Perth. He died in office at Bunbury on 16 November 1893.

Parry, Sir William Edward (1790-1855), fourth son of the notable physician and experimental agriculturist Caleb Hillier Parry, was born at Bath in England on 19 December 1790, and entered the navy in 1803 (lieutenant, 1810; commander, 1820; captain, 1821; rear-admiral, 1852), serving during the Napoleonic wars in the Channel, North Sea, Baltic Sea, and Arctic Ocean. The last-mentioned service, which involved three years' protection of English whalers off Spitzbergen, turned his attention to Arctic exploration, and from 1818 to 1828 he was almost wholly occupied with Arctic voyages, in the *Alexander* (1818), *Hecla* (1819-20), *Fury* (1821-3), and *Hecla* again (1824-5 and 1827-8)—in the last voyage reaching a latitude (82° 45′ N.) which was not reached again till 1876. His first *Hecla* voyage (in search of the north-west passage) was rewarded by election to a fellowship of the Royal Society in 1821; for the *Fury* voyage he was made acting hydrographer to the admiralty, an appointment confirmed in 1825. On 13 May 1829 he resigned this position to take up the commissionership of the Australian Agricultural Company (q.v.), whose affairs in New South Wales were in a bad state. He reached Sydney on 23 December 1829, established friendly relations with Governor Darling, and in the next four years inspected and secured for the company 600,000 acres of excellent land on Liverpool Plains, reorganized its coal-mining enterprise and obtained a definite grant of 2000 acres at Newcastle, and brought much-needed order and discipline into the management of the estates. In 1834 he handed over the management to Colonel Dumaresq and returned to England, where from 1837 onwards he was employed by the admiralty in various duties, ending his life as lieutenant-governor of Greenwich hospital. He died at Ems, while under medical treatment, on 7 July 1855. (Kt. Bach., 1829.)

See Gregson's *Australian Agricultural Company, 1824-1875* (Sydney 1907).

Parsley, Wild. See Apium.

Pasco, Crawford Aitcheson Denham (1818-1898), son of the Lieutenant Pasco who made the famous Trafalgar signal for Nelson in the *Victory* and later, in command of H.M.S. *Hindostan*, brought Macquarie out to Australia and took Bligh back (Macquarie praised him highly and wanted him as naval officer for the colony), was born at Plymouth in 1818, entered the navy in 1830, and in 1837 was appointed to H.M.S. *Britomart*, which under Owen Stanley sailed in January 1838 with Bremer in H.M.S. *Alligator* to establish a settlement at Port Essington. Next year he was transferred to H.M.S. *Beagle*, and under Wickham and Stokes took a large share in surveying both the north-western coast (1839-41) and Bass Strait (1842). After nearly 10 years of further service (largely in the Malay Archipelago) he returned to England, obtained two years' leave, and migrated to Melbourne in the P. & O. steamship *Chusan*, the first vessel of that company that was sent to Australia; Pasco was given a free passage in her because as far back as 1846 he had suggested the extension Australia-wards of the mail-services to the East Indies. In September 1852, not long after his arrival in Melbourne, Latrobe made him water-police-magistrate at Williamstown; he therefore retired from the navy, with the rank of commander, and settled at Melbourne, where he died on 18 February 1898.

His book *A Roving Commission*, published in Melbourne in 1897, is a brisk narrative of his long sea-services, and contains an interesting account of early days in what is now the Northern Territory.

W.J.

Pasley, Charles (1824-1890), eldest son of the Sir C. W. Pasley who was one of the greatest engineer officers of the 19th century, was born at Chatham on 14 November 1824, educated at the

Royal Military Academy, Woolwich, and given a commission in the Royal Engineers on 20 December 1843 (lieutenant, 1846; captain, 1854; brevet-major, 1862; lieutenant-colonel, 1867; colonel, 1872; major-general, 1881). He was employed on survey work in Canada (1848-9) and in the superintendence of public works at Bermuda (1849-50), and in 1853 was appointed colonial engineer of Victoria—a post which, he soon found, included the duties of supervising building- and road-construction. In 1854 he was given a seat in the legislative council; in December he acted as aide-de-camp to Captain Thomas at the Eureka Stockade. When Victoria was given self-government in 1855, Pasley was taken into the Haines ministry as commissioner for public works, and was responsible for the building of government house and the houses of parliament. He left office on the defeat of the ministry in March 1857, but continued to render public service as trustee for the Mount Alexander railway and as member of a commission on colonial defence. In May 1860 he resigned all his positions and intended to return to England, but, hearing that the war in New Zealand was going badly, offered his services to General Pratt (who was taking as reinforcements to New Zealand all the British troops he could collect in Australia), and distinguished himself in trench-fighting against the Kaihihi pa. Invalided back to Melbourne in November 1860 and to England in May 1861, he was made engineer officer commanding at Gravesend, in 1865 was charged with the extension of Chatham dockyard, and in 1873 was made director of engineering and architecture to the admiralty. From this post he retired in 1882, and died at Chiswick on 11 November 1890.

His connection with Victoria had not ended in 1860. From 1864 to 1868 he was special agent in London for the colony, and was largely responsible for the acquirement of the *Nelson* and *Cerberus* (see NAVAL DEFENCE). From 1880 to 1882 he was acting agent-general for the colony. His other services to the Empire include a report on warship design (1871), another on improvements to the harbour of Alexandria (1881), and the designing of Devonport and Haulbowline dockyards, the barracks and college at Keyham, and the college at Greenwich Hospital. (C.B., 1880.)

Paspalum, a fodder grass (*Paspalum dilatatum*) introduced by Baron von Mueller in 1891 from South America. An ounce of seed which he sent to the then director of agriculture in New South Wales was divided between dairy-farmers at Wollongbar and along the Richmond River, and from this beginning spread till it covers more than a million acres and has assured the prosperity of dairy-farming on the rivers of the State's northern coast. This result is due to its extraordinary tenacity of life and power of spreading from the roots. As the forests of those river-valleys were destroyed, *Paspalum* was the only grass capable of competing with the numerous and aggressive weeds that strove to take their place. For many years the grass was a poor seeder and was usually propagated by roots, but as it became acclimatized it began to grow well from seed also; it has become a grave pest in the gardens of one of the northern suburbs of Sydney, where it was introduced by a resident who kept a couple of cows. In the dairying districts, of course, it is controlled by steady feeding-off before the seed can be formed.

Its principal characteristics are its perennial habit, succulent wide leaves, rapid summer growth, ability to spread, palatableness when not in seed, adaptability to growth side by side with white clover, susceptibility to frosts and cold climates, and heavy carrying qualities. It should not be grown near lucerne land, as it will quickly spread there, and is extremely difficult to eradicate. If used for hay or silage, it should be cut before it comes into flower. *Paspalum* paddocks should be ploughed up every few years, otherwise the grass becomes impoverished. It is well suited to the coastal districts of Queensland and New South Wales, and to warmer and moist localities inland, particularly to irrigation areas; in these, however, care must be taken to prevent it from becoming a pest in orchards. See GRASSES.

E.B.

Pastoral Industry, THE, began in Australia with the first introduction of plants and seeds, cattle, sheep and a miscellaneous collection of horses, pigs, barn-door fowls, and turkeys (see FIRST FLEET and PHILLIP, ARTHUR). Among the first arrivals were one farmer and two persons with a slight knowledge of farming. All stock was the property of the government, which distributed to each married settler, each settler from the Marines, and each settler from the *Sirius* (q.v.), one ewe and as many she-goats as could be spared. Many of the sheep died soon after landing, in consequence, it was said, of the indigenous grasses being unsuitable. Some were killed by native dogs, and others were lost in various ways until only one remained. To add to these misfortunes the cattle strayed and were lost (see CATTLE); when all hope of recovering them had been abandoned, the remaining cow, having become wild and dangerous, was killed and eaten. More stock arrived from the Cape in 1791, and early in 1792 Governor Phillip urged the necessity for a further supply; some stock was imported from Bengal, but it proved unsuitable for breeding purposes. As soon as Phillip left the colony (11 December 1792) most of the stock was offered for sale, and, but that the officers purchased it, it would soon have been all killed off. Lieutenant-governor Grose (q.v.) encouraged the officers to preserve and breed from it by allotting 100 acres to those who applied for them. In January 1793 additions to the stock arrived, and in the following January the colonists had fresh meat for the third time since the founding of the colony. In 1794 the settlement at the Hawkesbury River was founded by J. Rous and C. Williams and about 20 others who had received grants of sheep and cattle. Special services were rewarded in this way; John Squires received a cow for growing hops, and John Macarthur (q.v.) 100 ewes as a reward for his enterprise and industry. By 1795 remarkable progress had been made by Macarthur on his farm at Parramatta, Richard Johnson (q.v.) was farming 600 acres, and Samuel Marsden (q.v.) was reckoned the most efficient farmer in the colony. In 1802 Governor King, wishing to encourage the 'men on the land,' introduced a system of premiums; three ewes were given to the man who raised the most maize or wheat, or bred the greatest number of swine, the object being to put the acquirement of stock within the reach of the industrious. Special inducements were held out by the English government for free settlers to migrate to New South Wales. By 1804 the

limits of the settlement entailed hardship on the smaller settlers who had not enough land on which to depasture their flocks, and in August, to remedy this, King granted a portion of the crown lands adjacent to the farming districts, and set out the boundaries of commons at what are now Pitt Town, Richmond, Windsor, Prospect, Baulkham Hills, and Field of Mars.

By this time there was a feeling in England that the government was plunging too deeply into affairs that properly belonged to the individual citizen. Lord Hobart issued instructions to King to diminish the amount of cultivation carried on by the government. This involved a decline in the number of stock bred and kept, and King mildly protested, representing that the state of the colony demanded government interference; stock-raising was continued for many years by the government, which further encouraged the industry by being the chief purchaser of cattle for the government stores. In the meantime Macarthur had persuaded the home government to make him a large grant of land for the purpose of raising sheep. He was given 5000 acres of the best land then known in the colony (now Camden Park) where he built up a fine flock of merinos (see SHEEP and WOOL).

The acreage for 1810 does not include the land under wheat.

Horses had multiplied greatly; by 1806 they numbered 552, of which 305 were mares. These were originally brought from the Cape and India, except one horse and one mare which came out from England in the *Buffalo* in 1802. The breed had improved, and they were bred in the bush at small cost. By 1810 the pastoral industry had again outgrown the settlement's boundaries, and matters were made worse by the droughts which occurred in 1812 and 1813. The position was acute when Gregory Blaxland, William Lawson, and William Charles Wentworth (see EXPLORATION BY LAND) solved the problem by finding a pass over the Blue Mountains (q.v.) to the rich plains beyond. Macquarie sent G. W. Evans with a party to examine the new country, and, acting on his report, employed William Cox to construct a road to give access to it. Early in 1815 Macquarie fixed the site of Bathurst, making large grants of land to all concerned in the finding and exploration of the newly discovered territory. Pastoralists immediately drove their flocks to the new land, and Macquarie, by giving them every encouragement, brought about a great increase in the stock of the colony and in the area of land cleared and tilled. Between 1815 and 1825 there arose a new type of pastoralist—the squatter.

John Macarthur, jun., made, and Commissioner Bigge (q.v.) supported, the proposal to form a joint-stock company (see AUSTRALIAN AGRICULTURAL COMPANY) that would seek unlimited range for flocks in the interior, 'not approaching nearer to the settled estates than five miles.' Bigge's reports were published in 1822-3, and an ever-increasing stream of superior immigrants began to come out, and, flowing over the boundaries of the settlement, gradually took possession of that greater New South Wales which lay outside the pale. The squatters had no little difficulty in gaining a footing; the British government would only allow approved settlers to migrate, and Macquarie permitted no one to depasture in new country without special authority from himself. Sir Thomas Brisbane, however, freely granted to reputable persons licences that were revocable at six months notice; the licence showed that, in his opinion, the holder was reputable enough to live beyond the recognized boundaries of settlement. The system was developed later by Sir Richard Bourke; in common with previous governors, he held that the land beyond the recognized boundaries was open to all to depasture on until it was required for the settlement itself. These licences cost the squatters £10 a year, together with a yearly assessment on each head of sheep, cattle, or horses; this revenue provided for the maintenance of a border police for the squatting districts. In 1846, when it was attempted to re-enact measures to restrain unauthorized occupation, strenuous opposition was made by Robert Lowe (see SHERBROOKE, LORD), Dr. Lang, James Macarthur, W. C. Wentworth, and Richard Windeyer, on whose motion the proposal was thrown out by the council; it was not brought forward again until Sir Charles FitzRoy's time. When flocks were being driven far to the north of the 26th degree, Fitzroy endeavoured to prevent the occupation of the country 'by private enterprise in opposition to the rights of the government;' but the squatters outside the pale united with those within and won a legal triumph. In the meantime the Australian Agricultural Company was established and landed its first shipment on 11 December 1825. At the beginning of 1846 the number of cattle within the pale was 417,000, and of sheep 1,891,000; the cattle without the pale numbered 698,000, and the sheep 2,518,000. The disparity was still more sharply accentuated in the Port Phillip district. There, only 30,000 cattle and 351,000 sheep were within the settlement, while 200,973 cattle and 1,430,914 sheep grazed outside it; the disproportion was still

greater in what was soon to become Queensland, where most of the grazing-runs lay outside the settled districts. In 1884 only 334 runs, containing 7,440,000 acres, were within the settled districts, whereas 9208 runs, held by a much smaller number of people, contained 308,669,026 acres. Following the extensive operations of the Agricultural Company in 1826, there came a sheep-and-cattle mania, when all sorts of people bought indiscriminately, 'outbidding each other in the most determined manner for every scabbed sheep, scarecrow horse, or buffalo cow that was offered for sale in the colony.' Agriculture was neglected, and when a severe drought occurred many were ruined. Since that time the pastoral industry has been carried on by men who have had some training, and rash speculation has largely ceased. In 1925 Australia produced one-third of the world's wool.

The 1920 and 1925 figures for the Federal Capital Territory are included in the New South Wales totals. In normal years between 130,000 and 160,000 sheep, about 7000 cattle, 1400 horses, and 400 pigs are depastured there.

Tasmania.—The industry began with the landing of stock by Lieutenant John Bowen (q.v.) at Risdon Cove on 27 September 1803. There were 9 cattle and 25 sheep owned by the government, a mare belonging to the commandant, a cow belonging to the doctor, and the officers and free-settlers Birt and Clark possessed 7 sheep, 8 goats, and 38 swine. After Lieutenant-governor Collins founded Hobart in 1804 the live stock was numbered at 20 head of cattle, 60 sheep, some pigs, goats, and poultry. The settlement at Port Dalrymple (see LAUNCESTON) was more successful. Colonel Paterson arrived in November 1804 and brought 1 horse, 4 head of cattle, 3 sheep, and 15 swine. To them were added from the *Buffalo* in March 1805 2 horses, 8 cattle, and 135 sheep. In the following month a shipment of 612 cows with 10 calves—the survivors of 910 shipped at Calcutta—were landed at the Outer Cove in charge of Ensign Piper; only 251 lived till the following spring. These were removed to Point Rapid, and later to the more fertile plains of the North Esk, since Yorkton had been found wholly unsuitable for a settlement. In 1813 the industry was retarded by the depredations of armed bushrangers (see BUSHRANGING), who pillaged, burnt, and slaughtered wholesale. Lieutenant-governor Sorell, who arrived in April 1817, did much to encourage the industry by granting land to new settlers in proportion to the capital they brought, and by guaranteeing 10s. a bushel for all wheat grown and 6d. per lb. for meat. The grantees spread themselves over the broad plains of the interior, and the finest parts of the island were alienated. The first stock was mainly of the Bengal breed, but the quality of sheep was improved in 1820 by the importation of 300 lambs from John Macarthur's flocks. In 1818 wool from Tasmania was considered worthless, but in 1819 the colonial government bought several tons at 3d. per lb., and the captain of an English trader accepted some in exchange for merchandise. In 1822 Henry Hopkins offered a cash prize for wool and bought 12 bales at 4d. per lb., the entire export of the colony for that year; it was sold in London at 7d. per lb. In 1823 550 bales were exported in one vessel. In 1821, when Governor Macquarie visited the colony, there were 15,000 acres of cultivated land, 35,000 head of horned cattle, 170,000 sheep, 550 horses, and 5000 swine.

In 1825 the Van Diemen's Land Company was formed to improve the quality of Australian flocks and so help to relieve Great Britain from dependence on foreign wool (see VAN DIEMEN'S LAND COMPANY). The company was responsible for introducing valuable stock into the colony, as were several settlers, notably Patrick Wood, who imported the Fifeshire breed, and Captain Watson, who brought the Normandy breed. Other immigrants brought Devon, Hereford, Durham, Holstein, and Fifeshire cattle in considerable numbers, as well as draught-horses and ponies. The foremost importers of stock were William Bryan, who had the best Devons, B. B. Thomas, Thomas Anstey, and Captain Wood. The importations from New South Wales were brought by W. R. Loane, Edward Lloyd, Colonel Geils, and Captain Barclay. In 1826 George Hobbler settled close to Launceston, bringing with him a few sheep and a Devon cow; many of the pure Devons now in Tasmania are descended from his famous 'Fair Maid.' P. Willis of Wanstead brought out good shorthorns and Captain Langdon some high-bred Devons.

Horses were first imported from New South Wales, but they were not of the best. About the end of the twenties some were imported from England and India, and the breed improved. A race-course formed in the early thirties helped considerably to better the breed of horses, but breeders for the most part gave more attention to draught-horses than to race-horses. The discovery of gold in the other colonies threw back the industry, for labour became scarce. After the rush was over, things returned to normal and the industry again flourished. The climate of Tasmania makes it highly suitable for stock-raising, and for many years Australia has imported stock for stud purposes from the island.

(*a*) County Cornwall only. (*b*) County Buckingham only.

Western Australia.—In 1829 Captains Fremantle and Stirling (q.v.) brought to the new colony 200 sheep, 51 head of cattle, 33 horses, and some pigs and poultry. In the latter part of 1829 and in 1830-1 a number of sheep were imported from Tasmania, the first lot being brought by T. Henty. About 3500 sheep in all were brought, but as there was thought to be little land suitable for grazing, nearly all were killed to supply the war-ships. At the same time Lord and Bryant imported 60 head of cattle, some of which strayed into the bush

and formed wild herds; others were killed. In January 1830 the cattle numbered was 204, horses 57, sheep 1096, and pigs 106. The Swan River was the first part of the colony to be taken up, and the stock then spread down towards King George's Sound and Cape Leeuwin. Wooded land proved unfit for pasturing; some animals were lost in the thickets or died from eating poisonous plants, and the lack of water was a serious handicap. Gradually the depasturing circle was extended, and the neighbourhood of the Irwin River in the East Victoria district became noted for its cattle. Among the first farmers to settle on the Swan River were Joseph Hardy from Lincolnshire and B. Clarkson from Yorkshire, who as early as 1833 had bred a race of tall handsome horses from a large breed which they had brought out and crossed with Cape mares. A number of farmers were becoming prosperous, and by 1835 the pastoral industry was well established. On 23 August 1835 the Western Australian Association was formed 'for the purpose of watching over the interests of the settlement known as the Swan River Colony,' and at the end of the year George Moore, advocate-general, reported that there were 1000 acres under wheat, 5000 sheep, and an export of 5 tons of wool. In 1837 John Hassall, on his way to England, was so impressed with the possibilities of the colony that he brought from London a shipment of merchandise which he sold in Launceston; proceeding to Sydney he chartered the *China* which he stocked with sheep, cattle, horses, other live stock, provisions, implements, etc. and sailed for King George's Sound, where he landed on 1 March 1840. He settled at Kalgan and attracted a number of new settlers round him.

Sheep and cattle were landed at various times from the *Lion, Thames, Bussorah,* and *William,* but of the 10,641 sheep brought in these vessels not more than 1200 to 1500 reached the settlers; many died after landing, or were sent to the butcher. On 6 November 1834 the first cattle-show was held, and an annual fair was begun at Guildford in 1836. During 1837 'remission tickets' were issued; these gave the occupiers of land the right to render back to the government two-thirds of the grant of land in their possession and to choose one-third the number of acres in another part of the colony.

In 1841 the Western Australian Company purposed buying large tracts of land at Australind near Leschenault and reselling it in farms of 100 acres. The scheme failed because at this time New Zealand and South Australia were attracting settlers. Labour became scarce, industries flagged, and a period of depression fell on the colony. With the sending of consignments of convicts cheap labour became available and a great impetus was given to the pastoral industry during the ensuing ten years. In September 1844 the first exported cattle were sent to the Isle of France in the *Unicorn,* and in October 1849 a Horse-rearing Company was established. The first horses were exported to India in 1851. Communication with the outside world was established by the Australian Mail Company on 20 August 1852, and the industry continued to progress. Local agricultural societies sprang up, the stock became much improved, explorations were made, and fresh country opened up. The first shipment of wool from the north-west arrived at Fremantle in 1864. During the seventies John and Alexander Forrest (q.v.) made expeditions across the southern portion of the colony and opened up fresh pastoral areas (see EXPLORATION BY LAND).

Victoria.—The first stock was brought by Thomas Henty from Launceston in the ship *Thistle,* which anchored in Portland Bay on 19 November 1834. A month later the *Thistle* brought his son Francis Henty with more sheep and cattle. Three other sons joined the firm a little later, and until 1842 worked in a fairly prosperous partnership in grazing, whaling, and wool-growing. In the meantime John Batman (q.v.) and John Pascoe Fawkner (q.v.) had settled at Port Phillip with herds and flocks, and the Port Phillip Association had been formed in Tasmania, each member being bound to bring over 1000 sheep within a year. On 26 October 1835 500 sheep and 50 Hereford cattle were landed on the scrubby shore where Williamstown now stands, and, within a radius of ten miles, by January 1836 there had been formed three stations, named Conolly, Swanston, and Solomon after the proprietors. The total white population of the Yarra settlement at this time was under 50, but they had over 100 head of cattle, 1400 sheep, 6 horses, and a stock of poultry. In 1836 John Aitken landed from Tasmania with stock, drove it across country, and formed a station about half-way between Sunbury and Gisborne. In the eyes of the authorities all these settlers were trespassers, and Governor Bourke sent George Stewart to report on the 'invasions.' Stewart was impressed with the importance of the new territory and pledged himself to further the settlers' claims for recognition. Bourke applied for authority to countenance the settlement, and received it; on 9 September 1836 he issued a proclamation notifying the authorization of the settlement at Port Phillip under the same crown lands regulations that were in force in other parts of New South Wales. At the same time Sir T. L. Mitchell reported favourably on the land in the western district, and a number of New South Wales squatters moved their flocks there. In February 1838 another migration took place, and in August 1840 it was estimated that 20,000 cattle were on the road between Yass and Melbourne. Many settlers who had formed stations on the upper Murray in 1836-8 moved on to the Port Phillip district, and over 100,000 sheep crossed the Murrumbidgee in three months. Stockowners flowed in from Tasmania, and the ripely experienced squatters soon brought the country to a producing stage that it otherwise might have taken a quarter of a century to reach. Within two years 250,000 sheep had been transported, about 50 stations formed, and the

greater part of the western district taken up. At first Geelong was the centre of settlement, and in 1837 about 30 stations were formed along the banks of the Moorabool, Barwon, and Leigh rivers, but a little later Melbourne and Portland became points of further settlement. In 1837 four Tasmanian squatters occupied the Colac country, finding one pioneer already there. Early in 1838 eight more took up unoccupied land round about Lake Colac, and Joseph Hawdon and John Hepburn led an expedition from New South Wales and formed near the Yarra the first cattle-station. In the same year Captain Howey took up a station near Gisborne, the first run connecting the squatters from Sydney with those from Tasmania, and in 1839-40 large numbers of stations were formed. Many of the pioneers were the discoverers of the land they afterwards occupied.

In 1838 G. D. Mercer and two others set out beyond the boundaries of settlement and, following up the creeks, discovered the country now occupied by four stations, and took up runs for themselves. A squatter and an overseer discovered the Mount Talbot country, one of the finest runs in the Port Phillip district. In 1847 a run was formed on the edge of the sandy desert forming the boundary of Victoria and South Australia, but for the most part only the richer parts of the country were at this time settled on by the graziers. When 'boiling-down' came into practice, and lean stock became valuable, the poorer country was occupied, and the northern plains and the Wimmera were settled. In 1839 Gippsland was discovered by A. McMillan, who returned in 1840 to form a station. It was 'rediscovered' by Count P. E. de Strzelecki (q.v.) whose glowing accounts of it soon brought 15 licensed and 7 unlicensed squatters from New South Wales, where at this time there was a drought. In 1842, owing to rash speculation, a depression fell upon the settlement (see BANKING) and the price of stock fell alarmingly. Henry O'Brien of Yass suggested the boiling-down of carcases for tallow; depreciation was arrested, and in a few years passed away.

It has been estimated that in 1856 the approximate area of the squatters' runs in Victoria was as follows:—

District.	Approximate Acreage.
Wimmera	9,358,849
Murray	6,132,726
Gippsland	1,845,232
Western Port	6,909,723
Portland Bay	7,103,306
Grant and Bourke	117,980
Total	31,467,816

Under the licences on which the land was held the squatters had certain pre-emptive rights, and up to 1856 they had exercised that right of purchase to the following extent:—

County.	Extent. acres.	Amount. £.
Anglesey	7,680	7,944
Bourke	7,360	8,816
Dalhousie	7,316	7,874
Dundas	10,160	10,555
Evelyn	3,560	3,560
Follett	2,240	2,240
Grant	17,363	18,327
Grenville	16,209	16,296
Hampden	16,800	16,912
Heytesbury	1,920	1,920
Mornington	14,156	14,431
Normanby	21,018	22,096
Polwarth	6,539	7,454
Ripon	13,760	14,011
Talbot	12,800	14,064
Villiers	20,320	20,505
Unnamed	98,520	99,783
Total	277,721	286,788

Following is the value in pounds sterling of the exports of wool and tallow, hides and skins from Victoria prior to 1859:—

Year.	Wool.	Tallow.	Hide and Skins.
	£	£	£
1837	11,369	28	22
1838	21,631	489	117
1839	45,226	396	249
1840	67,902	953	251
1841	85,735	786	561
1842	151,446	975	801

South Australia.—The first stock was landed in 1836 from the ship *John Pirie* by the South Australian Company (see SOUTH AUSTRALIA). It comprised six rams of merino and Leicester breed, two cows, and a few goats. In the same year 70 sheep, and a mare for the use of the manager of the company, were brought from Tasmania. The stock was grazed on the plains round Glenelg, and for a few years certain localities round Adelaide were known as No. 1 sheep station, No. 2 sheep station, etc. In 1837 more stock arrived from the Cape, Tasmania, and elsewhere, and the commissioners made land available on lease at 10s. a square mile, two square miles being allowed for each country section. On 3 April 1838 Joseph Haw-

don and Charles Bonney brought overland from New South Wales 325 bullocks, heifers, cows, and horses. Three months later E. J. Eyre (q.v.) brought 300 head of cattle, and in 1838 a third party under Charles Sturt (q.v.) arrived with 400 head of stock. In addition large numbers of sheep and cattle were sent by ship from New South Wales and Tasmania. To promote further importations a 'Joint Stock Sheep and Cattle Company' was formed with a capital of £20,000, and large purchases were made. In May 1838 the first four bales of wool were exported to England. In January 1839 the first 'special survey' of 4000 acres was applied for by Frederick H. Dutton, for himself, D. Macfarlane, and B. T. Finniss (q.v.), colonists of New South Wales, and in the same year Stephen King, one of the pioneers of the Gawler district, arrived. More stock was brought overland by Eyre in February and later by Captain Hart and J. S. Pullen from Portland Bay. In March one Wetherall arrived with 979 head of cattle and in April Finniss brought 700 head and 2500 sheep. At the end of the year, the Society for the Protection of Flocks and Herds was established.

Besides sheep and cattle, horses were brought in considerable numbers, the New South Wales stock-horse being considered the most suitable. The majority of the draught-horses came from Tasmania, a few thoroughbreds from England, some Arabs from the East Indies, and a number of small but hardy ponies from Lombok and Timor. Some settlers directed their attention to horse-breeding as well as cattle-breeding. J. B. Hack of Mount Barker had 120 horses and 1000 cattle in 1841. At the end of this year the South Australian Company had 20,000 sheep and was considered the largest owner in the colony; F. S. Dutton (q.v.) and C. H. Bagot (q.v.) had 11,000, and Duncan Macfarlane at Mount Barker and George Anstey at Parra had 10,000 each. The cattle held by the company numbered 1160 head; but the largest cattle-owners were Frew and Rankin, who had 1758 head on their station at Strathalbyn. In 1843 boiling-down was introduced and the manufacture of soap and candles was begun on a large scale. As sheep were a glut in the market at the time, thousands were boiled down for their tallow. While the South Australian Company had encouraged closer settlement and had imported much pure-bred stock which improved the industry and the conditions of the settlers generally, it was done with much loss to its own finances. The depression of the meat trade, at its lowest in 1848, was a severe blow, and in 1850 the company disposed of the whole of its flocks and cattle at Bremer and Mount Gambier stations as well as 472 acres at Mount Gambier. The discovery of gold (q.v.) in Victoria revolutionized the meat trade and squatting prospects; mutton and beef advanced to three and four times their previous value. For some years the prices kept up, but another depression in 1869 brought about the resumption of boiling-down. The establishment of the frozen-meat trade finally prevented sheep and cattle from becoming a drug in the market again.

Queensland.—The industry was established when Patrick Leslie in 1840 removed his stock from the New England district of New South Wales to the Darling Downs after exploring that country. Accompanied by 22 ticket-of-leave men, he drove his stock to the Condamine River and formed his stations and out-stations.

1925	255,022	400,423	6,359,240

Later, finding he had taken up too much country, he sold parts of it to various individuals and companies. One man is said to have been there before him, but Leslie is always reckoned the pioneer squatter of Queensland. In January 1840 John Campbell set out with two servants in search of a run and settled on the Gwydir, but his right was disputed. He then took up land at Bebo, and his men built huts while he made his cattle-camps on the other side of the river, becoming by accident the first stock-owner in Queensland, two months before Patrick Leslie passed the station on his way to the Darling Downs. David Colin McConnel followed Leslie's tracks as far as the Severn and then diverged, passing by Tenterfield and Stanthorpe. Crossing the Great Dividing Range, he settled on Cessbrook Creek, a tributary of the upper Brisbane River, in 1841. He was the first to settle with stock on a run east of the main range in Queensland. He brought pedigree shorthorn bulls imported by the Australian Agricultural Company, and, later, himself imported others from England. The herd thus bred still exists. Other squatters speedily followed. In 1841 a succession of pioneers settled on the Darling Downs. Joseph King and James Sibley formed King's Creek station on an affluent of the Condamine; Arthur Hodgson and Gilbert Elliott next settled at Etonvale; Henry Hughes and F. N. Isaac took up Gowrie; Henry S. Russell, Cecil Plains; the Gores occupied Yandalla and Tummaville; and Henry Dennis took up Jondaryan. By 1844 30 stations had been formed on the Darling Downs. All through the forties, fifties, and early sixties, successive waves of occupation flowed over the Queensland border, passed the existing stations, and settled on the great tracts of unoccupied land to the north. This necessitated the opening of fresh ports farther north on the eastern coast and in the Gulf of Carpentaria. A dozen pioneers settled on the lower Brisbane, although it was forbidden until May 1842 by the government's prohibition to settle without licence within 50 miles of the penal establishment at Moreton Bay.

After the Darling Downs, the northern and western watersheds received the pioneers. The Burnett was the first to be settled, the Halys being attracted to its upper reaches, and John

Eales, from Hunter River, settled at Wide Bay. Richard Jones, from Sydney, was the first to pass the range nearer Nanango, and others occupied land on the middle and upper Burnett. In 1853 the Archer family, pioneers of the Burnett district, set out to look for fresh country. Starting from Eidsvold, they passed by Rannes, the outmost station in that direction, occupied by the Leith-Hays, and came upon Gracemere Lake. Pushing on, they discovered and named the Fitzroy River and returned; two years later they established their head-station at Gracemere Lake. Others followed their lead; the Landsboroughs of Raglan settled near Gladstone, and John Young led the way northward and opened up the country between Gladstone and Rockhampton. After Leichhardt made his discoveries (see EXPLORATION BY LAND) pioneers pushed out towards Peak Downs. Among the first were Connor, Fitts, and B. B. Henning. William Stewart in 1861 overlanded from Victoria, and brought the first mob of cattle for two new stations on the Thomson. Both north and west, runs were taken up with astonishing rapidity. James Gibson was the pioneer in the Burke district and the first on the Flinders, where he stocked a number of runs. In 1863 James Rule and Dyson Lacy made a station at Aramac Creek, and in 1864 N. Buchanan crossed the Albert and settled at Beame's Brook station. Others followed on Gregory Downs, Donor's Hill, and in 1865 Edward Palmer, author of *Early Days in North Queensland* (Sydney, 1903), settled at Conobie. Captain John Mackay set out from Armidale in New South Wales in 1860, tracked the Pioneer River to the coast and secured the fertile valley it watered. In the following year he drove his cattle, horses, and bullock-teams overland and in 1862 formed his station.

QUEENSLAND STOCK RETURNS, 1839-1925.

1925	660,093	6,454,653	19,082,252

The Northern Territory was settled from Queensland, the first overlanders being D'Arcy Uhr with cattle, and Dillon Cox with horses, both in 1872. Mobs of cattle followed these pioneers, and by 1877 more than half the suitable land was taken up, though many of the runs were left undeveloped for a number of years. As pastoral occupation advanced, pastoral associations similar to that of the Musgrave Range took up immense areas all over the Territory. All the pastoral land from Port Darwin southeast to the Roper River and the Gulf country was taken up and stocked. Some runs were 6000 miles square and carried 2000 head of 'fats.' Fat cattle were shipped in the eighties from Glencoe to Batavia and Singapore.

The following table gives the numbers of stock in the Northern Territory in various years, commencing with the first available returns:—

NORTHERN TERRITORY STOCK RETURNS, 1880-1925.

Year.	Horses.	Cattle.	Sheep.
1880	2,372	19,720	9,318

1925	44,420	851,351	6,194

See AGRICULTURE, AUSTRALIAN AGRICULTURAL COMPANY, CAMELS, CATTLE, HORSES, PIGS, SHEEP, WOOL.

Paterson, ANDREW BARTON, born near Molong in New South Wales on 17 February 1864, educated at the Sydney Grammar School and trained for the law, at an early age found time to combine with his legal work the writing of cheerful verse inspired by the life of the plain- and hill-stations on which he spent his holidays. In the early nineties his pen-name 'Banjo' became familiar and welcome to readers of the *Bulletin*, and in 1895 his first volume of verse—*The Man From Snowy River*—achieved at a bound the popularity which it has never since lost. He was war correspondent for the *Sydney Morning Herald* in the South African war, saw some of the Boxer war in China, and then became for two years editor of the Sydney *Evening News*, and for another two of its weekly colleague the *Town and Country Journal*. In 1906 he published *An Outback Marriage*, which has great merit as a collection of bush incidents. In the war of 1914-18, as he was over age for active service, he was commissioned lieutenant in the remount service and attached to the Egyptian depot of the Australian Imperial Force, returning to Australia at the end of the war with the rank of major.

Both '*Bulletin* bards,' and both describing to townsmen the genuine life of countryfolk out back, Paterson and Lawson supplemented each other. Lawson's favourite subjects were the swagman, the rouseabout, and the small selector, and his moods were consequently inclined to pessimism or at best to grim endurance. Paterson's bush is the home of the optimist—usually a horseman, squatter, or drover—who takes his troubles in his stride. His literary value is below that of Lawson at his best; but as an interpreter of Australia, whether in cheery verse or in phrases of song that are often shot with true poetry, he is equal to the best of Australian writers, and has a larger sale outside Australia than any other. Up to 1925 90,000 copies of *The Man from Snowy River* had been sold.

Besides the two volumes named above he has published *Rio Grande's Last Race and other verses* (Sydney, 1902), *Saltbush Bill, J.P., and other verses* (Sydney, 1917), *Three Elephant Power and other stories* (Sydney, 1917), and, as editor, *Old Bush Songs* (Sydney, 1905). A collected edition of his verses was published in 1921.

Paterson, WILLIAM (1755-1810), born at Montrose in Scotland on 17 August 1755, at an early age devoted himself to scientific pursuits, more especially the study of botany. In 1777 he visited South Africa and made several expeditions into the Kaffir and Hottentot country east

of the then very limited Dutch settlements; a volume describing these journeys was published in 1789 and dedicated to Sir Joseph Banks. In 1781 he was commissioned ensign in the 98th regiment for service in India (lieutenant, 1783; captain, 1789; major, 1795; lieutenant-colonel, 1798; brevet-colonel, 1808); in 1787 he transferred to the 73rd; two years later he obtained through the influence of Banks a captaincy in the just-raised New South Wales Corps, probably in order to study the botany of a new country in which Banks was interested. He reached Sydney during September 1791, and was sent on to Norfolk Island with its new lieutenant-governor King. Returning at the end of 17 months, he began a series of expeditions into the Blue Mountains, partly to obtain plants for Banks, partly to discover a way across them; in the latter effort he failed, as so many did later, because he entered them by the Grose valley (which he named, though its existence had been known for some years) and was consequently confronted by impracticable rapids along the stream and impassable cliffs (see EXPLORATION BY LAND). When Grose left the colony in 1794 Paterson succeeded to the command of the corps, and from 17 December in that year administered the government until Hunter took it over on 11 September 1795. His administration, while it seemingly satisfied both Hunter and the authorities in London, was weak and characterless, and allowed the military settlers to strengthen their hold on affairs—thus leading up to the perpetual contests with Hunter and King and the final mutiny against Bligh.

In August 1796 Paterson was invalided to England, and during his stay there was promoted lieutenant-colonel and given a fellowship of the Royal Society. Returning to Sydney on 3 November 1799, he resumed command of the corps, and on King's recommendation was in 1801 made lieutenant-governor of the colony. King, it may be noted, describes him as 'a weak, honest man' who 'if he acted from his own ideas of right and wrong would do the right thing'—an estimate confirmed by Paterson's later behaviour. He was, however, spirited enough to challenge Macarthur to a duel, in which he was wounded (see DUELLING).

In June-July 1801 King sent him to explore the Hunter River, the upper part of which was for some time known as the Paterson; and in 1804 he was chosen to plant a settlement at Port Dalrymple in northern Tasmania. There he hoisted the British flag on 11 November, and, exploring the estuary to tide-limit, discovered and eulogized the site of Launceston (q.v.), but inexplicably deferred the establishment of a settlement on it until he had found his first choice, York Town (afterwards called Yorkton), unsuitable. By 1807, however, Launceston (which King wanted to call Patersonia, but was thwarted by the modesty of his subordinate) was occupied, and justifying its choice. Here Paterson—whose jurisdiction extended to lat. 42°S., Collins having the rest of the island in his charge—ruled mildly, more interested in fossils, lerp-insects, and the digestive powers of the Tasmanian wolf than in public affairs, until on 2 March 1808 he heard of the mutiny against Bligh. His first impulse was to proceed to Sydney and take over the government, and he ordered Johnston to send him a vessel; when it arrived, however, it brought information that Foveaux had been made lieutenant-governor (though only during Paterson's stay in Tasmania), and, weary and ill, welcomed the respite and decided to remain outside the turmoil until he should receive definite instructions from London. Foveaux, however, was anxious to shift his responsibility, and on 1 January 1809 Paterson reached Port Jackson, took over the administration on the 9th, and for once acted with firmness: he insisted on Bligh's return to England—and on Johnston's—and confined Bligh to barracks until he agreed to go. (For fuller details of these confused times, see BLIGH, WILLIAM.) This spasm of activity soon ended. Paterson was really ill, and spent most of 1809 recruiting his shattered health in the quiet government house at Parramatta. When Macquarie arrived at the end of the year, Paterson retired into obscurity, embarked with his corps in the *Dromedary* on 12 May 1810, and died aboard her off Cape Horn on 21 June. His conduct in accepting the results of the mutiny instead of restoring Bligh was over-harshly condemned, largely because Foveaux—who in 1808 had assured Paterson that Bligh's conduct had been insufferable—sheltered himself for Macquarie's benefit behind Paterson's alleged approval of the mutineers. But this did not prevent Macquarie from confirming to his widow a grant (made by Foveaux) of 2000 acres of Tasmanian land.

Patey, SIR GEORGE EDWIN, born at Montpellier near Plymouth on 24 February 1859, joined the navy in 1872 (sub-lieutenant, 1878; lieutenant, 1881; commander, 1894; captain, 1900; rear-admiral, 1909; vice-admiral, 1914), served in H.M.S. *Shah* in the Zulu war, and in H.M.S. *Barfleur* during the Cretan insurrection of 1896-7; in 1901-2 he was assistant-director of naval intelligence. In 1910-11 he commanded the second division of the 2nd battle squadron, and in 1912 was selected to command the just-established Australian squadron (see NAVAL DEFENCE). In September 1913 he brought out H.M.A.S. *Australia* (q.v.), took charge of the squadron, and within the next year so trained the young personnel and organized the shore establishments that on the outbreak of war in August 1914 Australian warships took their share of active duty from the first moment without a hitch. The admiralty would not allow Patey to hunt down the German cruiser squadron in the Pacific, whose position he estimated correctly within a fortnight of the commencement of hostilities; instead, he was set to escort expeditions which annexed German island groups, patrol the western Pacific until November, and then take the *Australia* to European waters. In March 1915 he transferred his flag to the *Leviathan* and took command of a squadron (including two Australian light cruisers) which patrolled the coasts of North America and the West Indies; in September 1916 he retired from active service. (M.V.O., 1903; K.C.V.O., 1913; K.C.M.G., 1916.)

Paton, JOHN GIBSON (1824-1907), was born at Kirkmahoe near Dumfries on 24 May 1824 and educated at the parish school, Dumfries Academy, and the Free Church Normal School, Glasgow (D.D., 1891). At 12 he entered his father's business, and in 1847 joined the Glasgow City Mission, to which he was attached for ten years. Responding to a call for missionaries for the New Hebrides, he was ordained at Glasgow, sailed in the *Clutha* in April 1858, accompanied by Joseph Copeland, and landed on Aneityum on 30 August. He settled at Port

Resolution, Tanna, where he endured great hardship and faced many perils. Four years later he visited Australia and collected £3000 towards the cost of a vessel, the *Dayspring*. In 1863 he visited Scotland to obtain missionaries, returning in 1866 and taking up work at Aniwa. The *Dayspring* having been wrecked, Paton visited Australia and New Zealand to collect money to build another. In 1881 he left Aniwa a Christian island and became Foreign Missions agent for the Presbyterian Church of Victoria. In 1884 the Victorian general assembly sent him to Britain to raise money for the purchase of an auxiliary mission ship, to cost £6000. He was successful, returning with £9000, which built the vessel and enabled him to establish new stations. From 1881 to 1901 he toured the world in the interest of the mission, and then made his headquarters at Melbourne. In addition to much translation work, including that of the whole New Testament into the language of Aniwa, he published *The Kanaka Labour Traffic to Queensland* (Melbourne, 1892); *Slavery under the British Flag* (Woodford, 1892); and *The New Hebrides: is France or Britain to Annex them?* (Glasgow, 1885); his *Autobiography* (London, 1889) passed through many editions and contains many interesting particulars of his career. He died at Melbourne on 28 January 1907.

J.C.

Patteson, JOHN COLERIDGE (1827-1871), born in London on 1 April 1827, educated at Eton and Oxford (B.A., 1849), and ordained deacon in 1853, was in 1854 selected by Bishop G. A. Selwyn (q.v.) for missionary work in New Zealand and Melanesia. In February 1861 he was consecrated first bishop of Melanesia, with headquarters in New Zealand, but in 1867 moved his headquarters to Norfolk Island, where the climate was more congenial for native trainees under instruction for missionary work. He protested unavailingly against the evil doings of Queensland and Fijian labour-recruiters in the islands, and in the end fell a victim to their malpractices; on 20 September 1871 the natives of Nukapu (in the Santa Cruz group), desperately angered against all white men, avenged the recent kidnapping of five of their young men by clubbing him to death. His body was set adrift in a canoe, and recovered by the missionary party.

Peacock, SIR ALEXANDER JAMES, born at Creswick in Victoria on 11 June 1861, entered the public service as a teacher in 1874, but after five years turned to politics by way of the Australian Natives' Association, of which he was a director in 1883 and president in 1885-6. In March 1889 he entered the Victorian assembly as member for Allandale, which seat he has held ever since. In November 1890 he joined the Munro ministry without holding a portfolio, and thus commenced a ministerial career which lasted (with short breaks in 1893-4 and 1899-1900) almost continuously until June 1902; from February 1901 to June 1902 he was premier, and again from 1914-17, and in 1924; he held minor offices in 1907-8, 1918-24, and 1925. He has in several ministries done good work as minister for public instruction. (K.C.M.G., 1902.)

Peanuts. The peanut, earthnut, or groundnut, *Arachis hypogaea*, supposed to be a native of the western coast of South America has become naturalized in many parts of the world—India, China, Japan, the United States of America, and other countries—where it is cultivated extensively for commercial purposes. It was introduced into New South Wales before the middle of last century, but no efforts were made to cultivate it commercially until after the war of 1914, although it had been found to thrive admirably in many parts of the Commonwealth. About 1895 trials were made at the government experimental farm, Wollongbar, Richmond River, New South Wales, which demonstrated conclusively that satisfactory yields could be produced in Australia; but although considerable quantities were imported, no attempt was then made to grow them for the market. In Queensland an area of 102 acres was under crop in 1915; this yielded 85,864 lb. and since then the area has been increased. There is now an import duty of 6d. per lb. on shelled and 4d. on unshelled peanuts. There are so many uses for this nut—the production of oil, peanut butter, peanut flour, and in confectionery—that it is likely to be grown in large quantities in Australia.

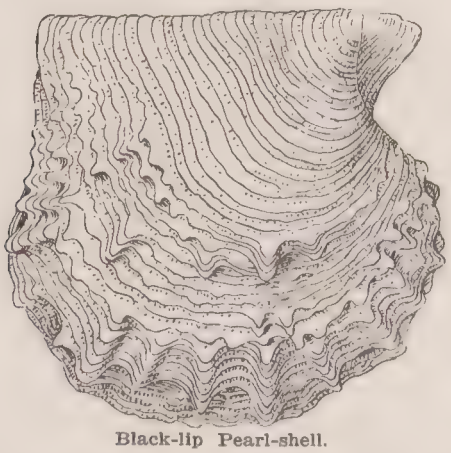
W.S.C.

Pearce, GEORGE FOSTER, born at Mount Barker in South Australia on 14 January 1870, moved to Western Australia in 1892 and was for a time resident on the goldfields. He identified himself closely with the labour movement, and was secretary to the united trades council in Western Australia in 1896 and president in 1899. In 1901 he was elected one of the six representatives of Western Australia in the first federal senate, and has retained his seat ever since. In 1906 he was appointed chairman of committees; he was minister of defence in the first Fisher ministry (1908-9), and the second (1910-13), and held the position continuously in the third of Fisher's ministries and all four of Hughes, until December 1921, thus becoming responsible for the military side of the Australian effort throughout the war of 1914-18, and up to July 1915 for the naval side also. In 1921 he was transferred to the home and territories department, which he held till June 1926 when he was appointed vice-president of the executive council. His political career has well exemplified the sober progressiveness of the pre-war Labour party. His administrative career has mainly consisted in a careful choice of the best available permanent advisers and in giving them an intelligent support; to this steadily pursued policy was due the success of two great experiments in defence conducted mainly under his supervision—the introduction of compulsory military training and the organization and despatch of the Australian Imperial Force in 1914-15.

Pearl Perch. See JEWFISH.

Pearls and Pearling. Several species of oyster have a shell with a nacreous lining, and may exceptionally produce a pearl, but only three species of pearl-oyster are recognized in commerce—the golden-lip, the black-lip, and the Shark Bay shell. By far the most lustrous and valuable is the Golden or Silver-lip (*Pinctada maxima*), which in Australian waters occurs on the tropical coasts between Exmouth Bay on the west and Townsville on the east. This is much the largest of the family, the weight of a pair amounting to over eight pounds. The handsome and valuable pearls that this oyster often

contains are regarded as a by-product; the trade depends on the oyster-shell itself, the mother-of-pearl, which is exported for manufacture into knife-handles and articles of jewellery. The Black-lip (*Pinctada margaritifera*) ranges be-



Black-lip Pearl-shell.

yond Australia to Ceylon and the South Sea islands. Both in size and in the quality of its nacre and pearls it is inferior to *P. maxima*. The Shark Bay shell (*Pinctada carchariarum*) is a small kind, peculiar to the Shark Bay district, and (like the Ceylon shell) is gathered

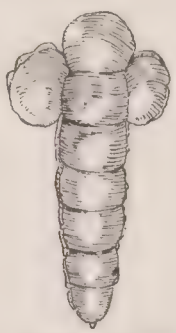
Pinctada carchariarum.

for the pearls, not for the shell. The oysters are separated from the shell and thrown into a tub to rôt; when the mass is softened by decomposition, the contained pearls are strained out uninjured.

The pioneer of Australian pearling was one Tays, an American sailor who settled at Nickol Bay in Western Australia. Recognizing the value of the pearl-shell strewn about in abundance, he began in 1861 to gather it for export. When the beach itself had been stripped of shell, aboriginals were engaged to dive off-shore; when they had reached the limits of their endurance (about 50 feet), diving-dresses were procured for them, so that the shell might be followed into still deeper water. The industry expanded so fast that in 1871 the western fishery employed a fleet of a dozen vessels of from 15 to 90 tons burthen, which collected in the aggregate 180 tons of mother-of-pearl.

The Torres Straits fisheries began in 1868, when William Banner, master of the brig *Julia Percy*, commenced operations at the Warrior Reefs. The industry grew rapidly, and in 1871 ten vessels secured nearly 200 tons of shell. By 1883 the Queensland pearling-fleet consisted of 206 vessels. As the fisheries grew in importance the government was obliged to regulate them by various restrictions and enactments. Both men and boats were licensed, the gear submitted for inspection, and limits placed on the size of the shell and on the depths from which it might be taken. In fair weather and with modern diving-dress a diver may spend two hours at a time in water from eight to ten fathoms deep. In greater depths his stay must be shorter, and in 30 fathoms he risks his life by a visit of more than a few seconds. The oysters are so scattered on the floor of the sea that a good deal of walking is necessary to find them; they lie about, either loose or fastened by strings to a rock. Usually the valves gape apart, and the diver must take care that his fingers are not nipped when they close.

Among famous Australian pearls the 'Southern Cross' is notable. It was found off Baldwin in Western Australia in 1883. It is formed of nine separate pearls, grouped in the form of a cross 1½ inches long; seven form the shaft, two—not well balanced—the arms; the individual pearls are not of great size or beauty, and the gem's value depends on its unusualness. The finest pearl yet found in Australian waters is a drop-shaped gem the size of a sparrow's egg, weighing 100 grams, which was found on the Western Australian coast in 1917. It was named 'The Star of the West' and valued at £14,000.



'Southern Cross' compound pearl.

The average annual product of the pearling industry in 1920-24 was:—pearls, value £48,678; pearl-shell, 2197 tons valued at £301,407. About two-fifths of the product came from Queensland and the rest from Western Australia. There is an infant pearling industry in the Northern Territory, but the production is at present insignificant; in 1924 only fourteen tons were obtained there, and pearls valued at £200 were found.

Pears. See APPLES AND PEARS, FRUIT-GROWING and PLANT-BREEDING.

Pearson, CHARLES HENRY (1830-1894), born at Islington near London on 7 September 1830 and educated at Rugby, King's College, London, and Oriel and Exeter colleges, Oxford (B.A., 1852; M.A., 1854), after a distinguished career as fellow of Oriel (1854-73), professor of modern history at King's College (1855-65), and lecturer on modern history at Trinity College, Cambridge (1869-71), in 1871 migrated to South Australia, which he had already visited in search of health in 1865-6. In 1874 he lectured on history at the university of Melbourne, and in 1875 became the first headmaster of the Melbourne Presbyterian Ladies' College. In 1877 he was made a royal commissioner to investigate edu-

cation in the colony, in 1878 entered Victorian politics as member for Castlemaine, and accompanied Graham Berry (q.v.) on his 'embassy' to England. In Berry's third ministry (1880-1) he was minister without portfolio, and administered the education department in the Gillies-Deakin coalition of 1886-90. From 1883 to 1892 he was member for the East Bourke boroughs. His chief work as minister for education was the separation of secondary from primary education, mainly by (*a*) lowering the limit of compulsion from 15 years of age to 13, thus releasing at the lower age all children not intended to pursue a secondary course, (*b*) founding 200 scholarships annually for primary students intending to enter high schools, and (*c*) establishing 14 technical schools; among his other reforms was the improvement of art teaching in the state schools. As official champion of an educational system which from 1873 onwards had been avowedly 'free, compulsory and secular,' he incurred bitter opposition from the advocates of a denominational system. Leaving office with his colleagues in 1890, he became Australian correspondent of the London *Speaker*, and with his always detached and often caustic criticisms of Australian affairs awoke further ill-feeling against himself. At the elections of 1892 he refused to stand, and in August of that year left Melbourne for England. There he was made permanent secretary to the Victorian agent-general's office; but in 1894 he was informed that the Victorian ministry had decided to retire him—on the ground that their secretary ought to be a sort of export agent and purveyor of Victorian products, not a man of books and ideas. On 29 May he died.

Pearson was a man of the type which is so easily described—and dismissed—as 'unsuited to colonial life.' Cultured and aloof from the petty partisanships of local politics, he certainly found the conditions of colonial life trying. But without him, and a few like him, Australian literary and political life would have been immeasurably poorer; nor would he, probably, have been so valuable in England among a number of learned historians as he was in Melbourne, lonely on a peak but calling others up to him. His principal historical work, done in England, included a *History of England During the Early and Middle Ages* (London, 1867) and *Historical Maps of England During the First Thirteen Centuries* (London, 1867); the literary fruit of his Australian career was *National Life and Character* (London, 1893), a pessimistic prophecy which has come unexpectedly true in certain details, while its central contention—that the world's future lies with the yellow and black races—is still mere hypothesis.

Stebbing's *Charles Henry Pearson* (London, 1900) includes autobiographical matter for the English period of his life.

Pedder, Sir John Lewis (1784-1859), born in England in 1784 and educated at the university of Cambridge (LL.B., 1822), had already studied for the bar and had been admitted at the Middle Temple in 1820. On 18 August 1823 he was appointed chief justice of Tasmania, and reached Hobart on 22 March 1824, bringing with him the new charter of justice for the colony. On 10 May he opened the first sessions of the supreme court. He soon struck out for himself, refusing to follow the chief justice of New South Wales (Francis Forbes) in granting trials by civilian juries, which he considered unconstitutional. In 1825, when Tasmania ceased to be an appanage of New South Wales, Pedder was appointed to both the executive and the legislative council of the colony—positions not easy to reconcile with his tenure of the chief justiceship. Arthur got on well with him, although he had to complain of his meticulousness—'life is much too short to wait for his opinions and decisions'—as a councillor. With Franklin nearly anyone could get on. But Denison was of a different temperament, and in 1848 Pedder and he came into violent collision. The legislative council had passed an act under which dogs were taxed, and Pedder and his colleagues on the bench ruled that it was unconstitutional, because the council had no power to impose taxes for other than local purposes—a decision which also invalidated the acts imposing customs duties. Denison contended that the chief justice had neglected his duty, not having certified to the illegality of the measures within a fortnight of their enactment (as was the regular procedure), and tried to suspend Pedder, but the members of the executive council shrank from this action. Asked to take leave of absence till the matter had been referred to the authorities in England, Pedder refused thus to help the governor out of his difficulty. In the end the colonial office upheld Pedder, and gave Denison what Lady Denison described as 'an awful rap over the knuckles.' On 1 August 1854 Pedder retired, after 31 years' service, returned to England, and died there in 1859. (Kt. Bach., 1838.) T.D.

Pediculidae. See Sucking-lice.

Peel, Thomas, a near relative of Sir Robert Peel the statesman, was one of a body of capitalists who in 1828 formed an association for establishing a settlement at Swan River in Western Australia. They proposed, in return for a grant of four million acres of land, to send out 10,000 settlers with sufficient stock to keep them going; but the British parliament did not care to countenance colonization on so large a scale, and cut down the terms until all the promoters except Peel dropped out. He was in the end granted (*a*) a special reserve of 250,000 acres if he landed at least 400 settlers before 1 November 1829, (*b*) a further 750,000 acres in proportion to any further capital he might invest. As he did not land at Swan River until early in December 1829, and brought with him only 300 settlers, his special grant of land lapsed, but an area of 250,000 acres (known as Cockburn Sound Location 16) was provisionally assigned to him. Inefficiency and ignorance of local conditions rapidly brought about the failure of his scheme. His settlers obtained land independently, his stock wandered away, and a considerable quantity of the goods and chattels that he had brought with him rotted on Fremantle beach. As a recompense, however, for his attempt, his title to the Cockburn Sound location was confirmed in 1834. He settled down at Mandurah and died there, a disappointed, bitter, and comparatively poor man, in 1864. J.S.B.

Peel River Land Company. See Australian Agricultural Company.

Peerage, Australian. In 1853 W. C. Wentworth's select committee, appointed by the legislative council of New South Wales to draft a constitution bill (see Constitutions), recommended the creation of peers with hereditary titles to form a body from which members of the upper house under responsible government should be drawn. In 1852 a similar committee

had found great difficulty in devising a constitution for the upper house, and, though a tentative suggestion for a nominee chamber had been made, it was agreed that the subject required further deliberation. The committee of 1853 finally drafted two clauses, the object of which was explained at length in a report presented to the legislative council on 28 July 1853:

. . . Your Committee . . . desire to have a form of Government based on the analogies of the British Constitution. They have no wish to sow the seeds of a future democracy; and until they are satisfied that the nominated, or the future elective Council, which they recommend, will not effect the object they have in view, of placing a safe revising, deliberative, and conservative element between the Lower House and Her Majesty's Representative in this Colony they do not feel inclined to hazard the experiment of an Upper House, based on a General Elective Franchise. They are the less disposed to make the experiment as such a Franchise, if once created, will be difficult to be recalled.

Actuated by these views, your Committee have introduced into the Bill 'to confer a Constitution on the Colony, and to grant a Civil List to Her Majesty,' two clauses, which, to a certain extent, are framed in accordance with analogous clauses to be found in the Imperial Act, 31 Geo. III, c. 31, 'for making more effectual provision for the Government of the Province of Quebec.' That Act authorizes the Crown, whenever it thinks proper to confer any hereditary title of honor, rank, or dignity, to annex thereto an hereditary right of being summoned to the Legislative Council. Your Committee are not prepared to recommend the introduction into this Colony of a right by descent to a seat in the Upper House; but are of opinion that the creation of hereditary titles, leaving it to the option of the Crown to annex to the title of the first Patentee a seat for life in such House, and conferring on the original Patentees and their descendants inheritors of their titles a power to elect a certain number of their order to form in conjunction with the original Patentees then living, the Upper House of Parliament, would be a great improvement upon any form of Legislative Council hitherto tried or recommended in any British colony. They conceive that an Upper House framed on this principle, whilst it would be free from the objections which have been urged against the House of Lords, on the ground of the hereditary right of Legislation which they exercise, would lay the foundation of an aristocracy, which, from their fortune, birth, leisure, and the superior education these advantages would superinduce, would soon supply elements for the formation of an Upper House, modelled, as far as circumstances will admit, upon the analogies of the British Constitution. Such a House would be a close imitation of the elective portion of the House of Lords, which is supplied from the Irish and Scotch peerage; nor is it the least of the advantages which would arise from the creation of a titled order, that it would necessarily form one of the strongest inducements not only to respectable families to remain in this Colony, but to the upper classes of the United Kingdom and other countries who are desirous to emigrate, to choose it for their future abode.

On 29 July the *Empire* (Henry Parkes's newspaper) called on all citizens to oppose the two clauses in the draft bill providing for a colonial aristocracy with legislative functions 'which while it kept us slaves, would make us the laughing stock of every civilised nation.' A committee was formed to organize opposition, and on 15 August the disputed clauses were condemned at a meeting attended by many members of the existing legislative council, and resolutions passed in favour of a representative legislature consisting of two chambers elected by popular franchise. On the following day Wentworth moved the second reading of the constitution bill, which was carried on 2 September; but the opposition to his peerage proposals could not be ignored, and by 7 December (when the bill entered its committee stage) he had reluctantly agreed to abandon them, accepting in their stead the nominee principle for the upper house.

In 1918 Sir John Forrest was created a peer of the United Kingdom for services rendered to the Empire in Australia; in a sense, therefore, he may be called the only Australian peer. He died without issue.

Peewee. See MAGPIE-LARK.

Pelican, a very large aquatic bird (*Pelecanus conspicillatus*), the only member of the family Pelecanidae found in Australia. Its plumage is mainly white, the flight-feathers of the wings and the tail being black. Beneath the long beak is a large flesh-coloured pouch which is capable of being enormously distended to hold a large catch if the bird is successful in fishing. The Australian pelican has the distinction of being the largest member of the family, which has an almost world-wide distribution. It also differs from all other pelicans in that the patch of naked skin round the eye is separated from the bill by a feathered tract. It occurs in suitable localities throughout Australia, Tasmania, and New Guinea, chiefly inhabiting lakes and rivers, but sometimes appearing also on the sea-coast. It breeds on small islands off the

Pelican (*length* 36 *in.*).

coast, and in swamps in the interior. In southern Australia its numbers have been greatly reduced by fishermen and others, who regard it as an enemy, but the remnant now receive protection in most of their breeding localities. Pelicans, when once fairly started from the water, are strong fliers, and delight in circling at a great height in the air. They are sociable in habits, and often form large flocks.

The Australian pelican, like the black swan, was first seen by the Dutch explorer Vlamingh in 1697, on the Swan River in Western Australia. He mentions them in his narrative under the expressive old Dutch name of 'Kropganzen' (crop-geese). Two years later Dampier met with them in Shark Bay. W.B.A.

Pelsart, FRANCIS, a Dutch master mariner known only as the commander of the merchant-vessel *Batavia*, which in 1628-9 made a disastrous voyage from Holland towards the Dutch Indies. She left the Texel on 28 October 1628 in company with two other vessels, part of an expedition of 11 in all. Encountering severe weather, she found herself on 4 June 1629 alone off a little-known and very dangerous coast—the Houtman Abrolhos that lie off Geraldton in Western Australia—and just before sunrise

struck on a reef at their southern end, going to pieces some days later. Most of the provisions were salvaged, and the greater part of the crew and passengers reached two small islands in safety, but without any considerable supply of water. Pelsart, after a vain search through the neighbouring islets, decked the only boat left to him and made for the mainland. After coasting along for about 100 miles without finding any river or reliable water-supply, he determined to head for Batavia, and reached that port on 5 July; the governor lent him the frigate *Sardam*, and he returned to rescue the castaways. But during his absence a certain Jerome Cornelis, the supercargo of the *Batavia*, had made himself leader of a section of the crew, planned to seize eight chests of silver money that were part of the wrecked vessel's cargo, and murdered or outraged all who would not follow him to a career of piracy except a small party under a soldier named Weybehays. Pelsart on his return was forewarned by Weybehays (who had by good luck captured Cornelis), and with a little care managed to place the rest of the mutineers in irons; a few days later he called a council of war and on its advice hanged the lot, except two whom he put ashore on the mainland and who were never heard of again. He recovered five of the eight treasure-chests, and on 28 October sailed for Batavia. See AUSTRALIA, DISCOVERY OF. W.J.

Penguins, marine flightless birds of the family Spheniscidae, peculiar to the southern hemisphere, and most numerous in the Antarctic and sub-Antarctic regions. Several southern forms occasionally straggle as far as north as the coasts of Tasmania and southern Australia; but

Little Penguin (*length* 18 *in.*).

only one species, the Little or Fairy Penguin (*Eudyptula minor*), is resident in Australian seas, breeding in great numbers on some of the islands off the southern coast, and ranging north as far as Moreton Bay on the east coast and the Swan River on the west. W.B.A.

Pennant-fishes (*Alectis*), also known as 'diamond trevally' and 'silvery moon-fish' on account of their curious form and coloration, have greatly compressed and deep, angular bodies, with long filaments trailing backward from their dorsal and anal fins. Their form changes considerably with age, but they are brilliantly silver at all stages of growth. The genus includes two tropical species, ranging throughout the Indian and Pacific oceans—one even extends to the Atlantic. They are allied to the trevally (q.v.), and occasionally attain a length of nearly five feet. A.R.McC.

Pensions, OLD-AGE, INVALID, AND WIDOWS'. An old-age pensions scheme brought before the New Zealand parliament in 1896 proposed to allow 10s. a week to any aged person whose income—other than from personal exertion—was less than £52 a year. This bill did not pass. It was introduced in an altered form in 1897 (after a general election) and was rejected again; in 1898 it became law. The act granted a pension during good conduct to needy persons 65 years old and over. Although New South Wales was already spending £580,000 in charitable enterprises, in 1900 its parliament decided to introduce a system of old-age pensions; this was chiefly due to the exertions in 1897-9 of John Cash Neild, then representing Paddington in the legislative assembly, whose experience of the actuarial side of life-assurance business made him a valuable advocate. Victoria, however, was first in the field, for early in 1899 Sir George Turner, then premier, sent Robert Best and W. A. Trenwith to New Zealand to take note of newly-passed experimental laws there. They reported specially on the old-age pension system, and Sir George introduced a bill which was a copy of the New Zealand act, with certain additions intended to make for economy; but the Turner ministry fell in 1899, and nothing was done till it returned to office in 1900, when the bill was passed. It came into force on 1 January 1901.

In New South Wales Sir William Lyne on 13 September 1900 carried in the legislative assembly a resolution empowering him to bring in an old-age pensions bill; two months later the measure passed through parliament, but did not come into operation till 1 July 1901. Sir William frankly admitted that it was copied from the New Zealand law 'with certain important modifications.' The maximum pension was £26 a year, £1 being struck off for every £1 of other income in excess of £27. Any person earning £1 per week was debarred altogether. Married couples living together were entitled to only three-fourths of the two pensions; those living apart were allowed the full amount for each. A novelty in the Lyne act was that the officials administering the law were empowered to consider applications from needy persons 60 years old and upwards who were disabled by sickness or accident. Application for a pension-certificate was to be made to a board of three officials whose enquiries were to be private. Every £15 worth of property owned by a pensioner diminished the pension by £1, so that a person owning £390 was disqualified altogether. To qualify for a pension the applicant had to be a British subject who had lived in the colony for at least 25 years continuously —'continuously' meaning that his or her cumulative absences had not exceeded two years in the 25. In the case of Australians, residence in another State counted as residence in New South Wales, provided that the other State made reciprocal arrangements. Naturalized aliens must have been naturalized ten years before they could apply, and aborigines were classed with Asiatics and excluded altogether. The act forbade pensioners to live in charitable institutions; in this it differed from the law of New Zealand, where local poor-law boards were expressly forbidden to refuse to admit them.

The Victorian act, being intended to serve as a stop-gap while parliament and the ministry devised another, ran for six months only. Makeshift as it was, it affirmed the principle of old-age pensions, but there its merits began and ended. It provided that on and after 18 January 1901 every Victorian who had lived 20 years in the colony and was at least 65 years of age and poor, might apply to a justice of the peace

or police-magistrate for a pension of 1s. a day for four weeks in advance; during that period enquiry was made into the applicant's character and circumstances, and if the case was genuine the grant was confirmed. Persons under 65 might also claim pensions on the ground that their health had been ruined by working in mines or at some unhealthy trade. Alexander Peacock, Turner's successor in the premiership, pointed out the grave defects of this act, and substituted one which came into force on 7 December 1901 and cost the Victorian government £283,000 in pensions in the year ending June 1902. This act is notable for the number of its precautions and reservations, and for the care with which it tried to confine pensions to the enfeebled and utterly necessitous. It retained the clause in favour of those whose health had been injured by an unhealthy occupation—but no pension was to be paid under this section until the State treasurer had approved of it in writing. All claims were to be heard in open court (in this Victoria followed New Zealand, not New South Wales), but the examination was to be before commissioners, not magistrates. Notice of the hearing was to be sent to the police and to all charitable institutions in the neighbourhood, and the 'fullest evidence may be taken—whether strictly legal or not—as to the claim of the claimant.' The pension granted was a sum sufficient to bring a pensioner's income from all sources up to 8s. a week; an exemption of 2s. a week was allowed on earnings from personal exertion. If a claimant appeared capable of earning or partly earning his living, the pensions commissioner could either refuse the claim, or could grant less than 8s. a week. To be entitled to the two shillings exemption, the petitioner must have no more than £25 in goods of any kind. Applicants had to prove that they had made reasonable efforts to maintain themselves and, if they had a family, must show 'that the husband, wife, father, mother, or children of the claimant, or any or all of them, are unable to provide for or maintain the claimant.' Members of the claimant's family must show cause why they should not contribute to the claimant's support. Finally, no one could receive a pension-certificate unless he had executed a deed-poll undertaking—on demand—to transfer to the government all his real property; the treasurer might then sell the property, and deduct from the proceeds all sums paid to the owner by way of pension. These harsh restrictions resulted from the hopeless failure of Turner's temporary measure; some were necessary, and influenced both the New Zealand and New South Wales systems. The only other State in the Commonwealth to pass a pensions act was Queensland, whose act became law in July 1908.

The State acts were superseded by the Commonwealth invalid and old-age pensions act of 1908, which provided for the payment of old-age pensions throughout Australia from 1 July 1909, and of invalid pensions from 1 December 1910. The general administration of the act is in the hands of a commissioner, with a deputy commissioner in each State, who are empowered to summon witnesses, receive evidence, and require the production of relevant documents. The States are divided into districts, each in charge of a registrar who receives and investigates claims and keeps the necessary records. The age qualification is that laid down in the State acts, except that the age-limit in the event of permanent incapacitation for work is 60 years whereas for an invalid pension it is 16 years. The residential qualification for the old-age pension, first fixed at 25 years, has been altered to 20 years' continuous residence; for the invalid pension at least five years are required. The word 'continuous' has the same meaning as in the State acts. The applicant must be residing in Australia on the date of application, and must have become incapacitated while in Australia. The rate of payment is fixed by the commissioner or deputy commissioner; originally it was not to exceed £26 a year, and must not make the pensioner's total income exceed £52 a year; where an applicant was in receipt of board and lodging, this counted as an income of 5s. a week. In 1916 these amounts were altered to £32, £58 10s., and 7s. 6d. respectively; in 1919 the rate of pension was raised to £39 a year, the maximum amount of property to £65, and the estimated value of board and lodging to 10s. In 1920 special provision under the invalid pensions act was made 'for a permanently blind person, by which the amount of his pension may be at such a rate (not exceeding £39) a year, as will make his income, together with the pension, equal to an amount not exceeding £221 a year or such other amount as is declared to be a basic wage.'

Payments received by way of benefit from any registered friendly society, or during illness, infirmity, or old age, from any trade-union, provident or other society, are not treated as income. The pension may be reduced by £1 a year for every complete £10 by which the net capital value of the pensioner's property is in excess of £50. If both husband and wife are pensioners, the deduction in the case of each is £1 for every £10 by which the net capital value exceeds £25; if legally separated, the deduction for a single person applies. From the value of accumulated property is deducted the capital value of the pensioner's home, and all encumbrances on the property. Accumulated property (whether in or out of the Commonwealth) to the value of £310 disqualifies for a pension, as does the applicant's direct or indirect deprivation of himself of such property with the object of obtaining a pension. In the case of husband and wife, except when living apart, the net capital value of the accumulated property of each is deemed to be half the total net capital value of the accumulated property of both, and the amount of property allowed, prior to deduction, is £50 if including, and £25 if not including, a home. Good character is an essential for qualifying as a pensioner. For war-pensions see REPATRIATION.

The following table shows the working of the act since 1 July 1909:—

Year ending 30 June	Number of Pensioners.		Total payment.	Cost of administration.
	Old Age.	Invalid.		
			£	£
1910	65,492	.....	1,497,485	37,146
1911	75,502	7,451	1,871,240	39,244
1912	79,071	10,763	2,155,481	41,794
1913	82,943	13,739	2,302,335	44,523
1914	87,780	16,865	2,592,201	47,015
1915	90,892	20,417	2,731,939	48,018
1916	91,783	23,439	2,891,597	44,401
1917	93,672	26,781	3,554,135	54,393
1918	95,387	29,912	3,793,037	54,355
1919	95,969	31,999	3,936,615	63,280
1920	99,170	35,231	4,484,304	74,120
1921	102,415	37,981	5,150,241	88,271
1922	105,096	39,019	5,380,034	93,608
1923	107,389	40,064	5,423,016	87,910
1924	113,054	42,617	6,426,752	92,366
1925	117,516	44,840	6,896,401	94,486

J.V.C.-B.

Widows' Pensions.—The Widows' Pensions Act of New South Wales was passed by the Lang (Labour) government in 1925, and came into operation on 24 February 1926. At that date it was the only act of its kind in the Commonwealth. A pension is payable under the act to a widow domiciled in New South Wales at the date of her husband's death, residing in the State at the date of her application for the pensions certificate, having so resided continuously for three years previously, and having at the date of her application a child or children under the age of 14 years wholly or mainly dependent upon her for support. Continuous residence is not deemed to have been interrupted if the claimant's absences did not exceed in the aggregate a tenth of the total period of residence, or if she proves that during the period of her absences her family or home was in New South Wales. It is further stipulated that she must be of 'good moral character and sober habits,' and that the pension must be properly used. The act applies to women who became widows before the commencement of the act as well as to those who became widows subsequently, but the pension is not payable to aliens, to Asiatics not born in Australia, or to aboriginal natives of Africa, the islands of the Pacific, or New Zealand. It is at the rate of £1 a week for the widow and 10s. in respect of each child under the age of 14 years wholly or mainly dependent upon her. If the widow's net income exceeds £78 a year, the pension is reducible by £1 a year for each £1 by which the £78 is exceeded, but rent up to £78 a year paid by the widow is not deducted in the calculation of income. No deduction from the pension is made on account of the widow's ownership of a house, provided she lives therein; of furniture or personal effects; or of any amount exceeding 25 per cent of the earnings of a child or children over 14 years of age residing with her. Stepchildren, children legally adopted before the commencement of widowhood, or illegitimate children of the claimant not born during her widowhood are included in the benefits of the act. Claims are lodged with the clerk of petty sessions nearest to the place of abode, who makes the necessary enquiries and submits each claim to a police or stipendiary magistrate. He in turn makes his recommendation, to the registrar of widows' pensions. One of the chief objects of the act is to enable widowed mothers to remain at home and look after their children, instead of having to go out to work at the risk of neglecting them. The pension is granted for a period of one year, at the close of which application must be renewed. It must be forfeited when the pensioner becomes qualified to receive an old-age or invalid pension under a federal act. By 30 June 1926 the number of pensions granted was 4433, and the sum paid in respect of these £126,466; it was estimated that the total cost of the pensions would be £500,000 a year. On 31 March 1925 there were 65,500 widows in the State, with 35,600 dependent children; the estimated number of widows in 1926 was 66,500. The census of 4 April 1921 classified the widows of the State into the following age-groups:—under 30, 1788; 30-45, 9149; 45-60, 18,037; 60 and over, 31,727. The New Zealand widows' pensions scheme is on a lower scale, £52 a year being allowed to a widow with one child under 15, and £26 a year for each additional child under 15, the maximum allowance payable being £208 a year. L.G.W.

Pepper Tree. See MAGNOLIACEAE.

Perch. The English perch (*Perca fluviatilis*) has been introduced into many parts of Australia, but has not established itself in any numbers. Australian waters have yielded no indigenous species of the family Percidae, of which the English perch is typical; but the name has been locally applied to many widely different species, for which see BANDED SEA PERCH, BLACKFISH, EMPEROR BREAM, FRESHWATER PERCH, GIANT PERCH, GOLDEN PERCH, JEWFISH, MACQUARIE PERCH, ORANGE PERCH, RED PERCH, RED ROCK COD, and SILVER PERCH. A.R.McC.

Peripatus a primitive genus of arthropods so distinct from other arthropods that the class Prototracheata (or Onychophora) has been created for it alone. While indubitably an arthropod, since it breathes through special tubes (tracheae) like the majority of insects, its structure is in several other respects assimilated to that of the Chaetopoda or segmented worms; it is thus one of the rare links between distinct phyla of animals that help us to understand the meaning of evolution in the Darwinian sense. [*Ceratodus*, q.v., is another.]

Peripatus, though rare, is widely distributed; species are found in South Africa, the West Indies, South America, New Zealand, Sumatra, Borneo, and the Malay Peninsula, as well as in various parts of Australia. Bouvier, indeed, on anatomical grounds divides the Onychophora into several genera, confining the name *Peripatus* to the South American species, and classing the Australian and New Zealand species (except the oviparous forms to be mentioned below) under a new genus *Peripatoides*. For many years it was supposed that all the species were viviparous. Most of them certainly are; but in 1889 Arthur Dendy discovered that two Victorian species (one of which extends to Tasmania) and two or three species found in New Zealand are oviparous, the eggs possessing strongly-marked insect characters. This was important evidence of the relationship of *Peripatus* to the Insecta. For the oviparous form Dendy founded the genus *Ooperipatus*, of which the species *O. oviparus* occurs in Victoria, New South Wales, and Queensland, *O. insignis* in Victoria and Tasmania, and *O. paradoxus*, a very fine species, in Queensland. The females of *Ooperipatus* are characterized by the possession of a large fleshy ovipositor, which is lacking in the viviparous *Peripatoides orientalis*, the species most common in New South Wales, and in *P. gilesi* from Western Australia. The males of the two genera are, in the dark-coloured forms, quite indistinguishable from one another. But in New South Wales *P. orientalis* varies in colour from deep uniform black to light tawny-brown.

Ooperipatus insignis (x 6).

The food of *Peripatus* consists of insects, wood-lice, and the like, termites being a favourite article of diet. All the soft parts are eaten, including the legs of small insects. The antennae appear to be endowed with a sense analogous

to that of smell. The skin is cast at somewhat irregular intervals. In the case of young born in captivity, the first ecdysis occurs when the creatures are between one and two weeks old. The skin splits down the median dorsal line and its removal is aided by the animal's jaws. After being shed the skin is usually swallowed.

Peripatus is provided with an elaborate slime-secreting and discharging apparatus, consisting of a pair of large glands connected with papillae, one at each side of the mouth. The slime is used as a means of defence, or for securing prey, and is emitted from both papillae simultaneously with sufficient force to project it several inches. It is extremely viscid, and so embarrasses an enemy or hampers a struggling insect. The breeding-season of *P. orientalis* lasts from about the middle of November to the middle of March, individual females giving birth to their litter during about a month. They are about 5 millimetres in length when born, and over a period of 12 months grow at the average rate of rather less than 1 millimetre per month. *Peripatus* is a very sociable creature; its individuals do not molest one another, and love to crowd together in congenial lurking-places. Several may frequently be seen feeding in perfect harmony on one insect.

See Bouvier in *Annales des Sciences Naturalistes* (1907); Dendy in the *Quarterly Journal of Microscopic Science* (1902) and in *Zoologische Anzeigungen* (1906); and Dendy, Fletcher, and Steel in *Proceedings* of the Linnean Society of New South Wales, 1894-6. T.S.

Perlaria, an order of aquatic insects known as stone-flies, a very ancient group with no very near relatives in existence, though on the one side they show affinities with the Orthoptera and on the other with the oldest holometabolous orders (see INSECTS). They may be recognized by their habit of folding the wings closely down along and above the abdomen; the long slender antennae project forward, and the long cerci backward in the same line. The larvae are aquatic, and superficially not unlike those of may-flies, from which they may be distinguished by their possessing only two caudal filaments instead of three, and by the lack of the leaf-like, paired gills along the sides of the abdomen.

This order is abundant in colder regions, including Tasmania and New Zealand, where the beautiful Eustheniidae have their headquarters. A number of species of the type-genus *Eusthenia*, found in Tasmania, are certainly the most remarkable of all Perlaria. The best-known is *E. spectabilis*. Two beautiful (but rarer) species of this genus are shown on plate xix, *Eusthenia lacustris* (fig. 15) and *E. violacea* (fig. 16). The larvae of this genus are fierce, active, dark-green creatures, living upon the under-side of rocks in swift streams. They are furnished with gills in the form of a series of paired filaments upon the abdomen, resembling those of Megaloptera.

The only other family represented at all commonly in Australia is the Leptoperlidae, small inconspicuous insects very rarely seen by collectors. They emerge in the winter and early spring, and may be found sitting upon the stalks of reeds or grass, from which they are very seldom seen to fly. Several species have been described from Tasmania, but only two from the mainland. They are, however, abundant enough in their season, and the author has nearly 30 unnamed species in his collection. *Dinotoperla carpenteri* is a small blackish species found resting on grass-stems near water in the Sydney district; it is shown at rest in the text-figure. Their larvae are tiny inert creatures that cling

Dinotoperla carpenteri (at rest).

close to rocks under water, simulating growths of weed or moss. They are furnished with a beautiful tuft of pink gills round the anus.

See Sharp in *Cambridge Natural History*, and Froggatt's *Australian Insects*. R.J.T.

Perry, CHARLES (1807-1891), born on 17 February 1807 at Hackney near London and educated at Harrow and Trinity College, Cambridge (B.A., 1828; M.A., 1831; D.D., 1837) after studying for the bar entered the Anglican ministry (deacon, 1833; priest, 1836) and lived at Cambridge as fellow and tutor of his college (1829-41) and vicar of St. Paul's church (1842-7). On 29 June 1847 he was consecrated first bishop of Melbourne, and was installed there in St. James's cathedral on 28 January 1848. At his arrival there were only three Anglican clergy in the Port Phillip district; within a few years his diocese was the centre of the gold-rushes, and, having to create amid that turmoil a system of Church organization, he initiated in Australia the modern practice of government through an assembly composed partly of clergy and partly of laymen elected by the parishes. During his episcopate he stimulated the building of more than 300 churches in the diocese. In 1874 he returned to England, and in 1876 resigned the see; after a short holiday he became in 1878 chaplain to the order of St. Michael and St. George and prebendary and canon of Llandaff. He retired in 1889 and died on 2 December 1891. See CHURCH OF ENGLAND.

Perth, the capital of Western Australia, lies in latitude 31° 57′ S. and longitude 115° 50′ E. on the banks of the Swan River about 10 miles from its mouth. The site was chosen by Captain James Stirling (q.v.) when the colony was established in 1829, and the town was named Perth after the old capital city of Scotland and in honour of Sir George Murray, at that time secretary of state for war and the colonies, who was born in Perthshire and sat for that county in the house of commons. The town was founded on 12 August 1829, the birthday of King George IV; a rapid survey of the townsite was then undertaken, and the first allotments were offered for sale on 5 September following. During that month the officials and settlers, who had been temporarily accommodated on Garden Island, moved to the mainland, and by the end of the year the infant city had become a straggling village with a population of about 300.

Its progress, according to modern notions, was extremely slow, but in that it only reflected the progress of the colony generally. By the middle of 1837, eight years after its foundation, over 400 town allotments had been sold, and about 350 houses had been erected; four walls and a roof fulfilled all requirements, and even light and ventilation were secondary considerations. This absence of architectural pretensions was a distinguishing feature of Perth for many years; no attempt was made until after the introduction of the convict-system to replace the crude four-square buildings with anything more ornate. Want of money in those early days hampered progress even in such essentials as road-formation, but in 1840 the first step towards a modern policy was carried out by the construction of a causeway-bridge over the river-flats, thus bringing Perth into closer communication with outlying settlements.

It was not until 1856 that Perth, by the establishment of the bishopric, was constituted a city. Up to that time, and for many years after, local government was in the hands of a body called the 'town trust.' In 1871 a municipal institutions act was passed, and the city came under the rule of a city council; but its presiding officer was still called 'chairman,' until in 1880 he was given the more dignified title of 'mayor.' In 1864 the city was divided into three wards, and in 1867 the foundation-stone of the town-hall was laid by Governor Hampton; the building was completed in May 1870, and opened by Sir Frederick Weld.

Up to this time Western Australia had lagged behind the rest of the civilized world in modern facilities; in January 1869 there was not a single mile of telegraph-line or railway in the colony. In that year two private citizens, Messrs. Stirling and Cumming, erected a private telegraph-line between Perth and Fremantle, and opened it in June for public business. This stirred the government to action, and by 1872 Perth was connected by telegraph with Albany, Bunbury, and Toodyay. Further extensions were made, and at the beginning of 1875 the first pole of an overland line to Adelaide was erected; the line was completed by the end of 1877, and Perth was brought into telegraphic communication not only with the capitals of the eastern colonies, but through Adelaide with the cable-systems of the world. In June 1879 the first sod was turned of a railway intended to run from Fremantle through Perth to Guildford. This line, opened in 1881, formed the first section of that great network of railways which now connects the capital with practically the whole of the settled area of the State. Telephone facilities were not available in Perth until the end of 1887, but were quickly afterwards extended to Fremantle.

In 1889 a private company began the construction of a water-supply service from a catchment area in the Darling ranges. These works were purchased by the government in 1896 and placed under the control of a board, which in 1909 gave way to a department established to control water-supply, sewerage, and drainage throughout the metropolitan area.

The development of Perth into a modern city —and of Western Australia into a modern State —may be said to date from the gold discoveries of the early nineties. The placid life of the community was upset by the gold-seekers, many of whom came from cities replete with every modern requirement, and were dissatisfied with the antiquated buildings of Perth and the antiquated methods of its rulers. One by one the old-time buildings gave way to modern structures, not always architecturally correct, but on the whole along right lines. With the exception of St. George's-terrace—one of the finest thoroughfares in the Commonwealth—the streets are narrow from the modern standpoint, but the city council and the town-planning association are alive to that fact and are acting in concert to remedy it. The city is admirably provided with lungs—foremost among them being The King's Park, with an area of nearly 1000 acres.

Traffic facilities are met by electric trams and motor-buses (the former controlled by the government), and by a frequent suburban train-service reaching out to Fremantle on the one side and Midland Junction on the other. These facilities have brought into existence a metropolitan area stretching through a distance of over 20 miles east and west, mainly along the northern side of the river. Tram and ferry services, too, are rapidly making the south side desirable for residences. As with all other State capitals, the population of the metropolitan area is growing more rapidly than that of the country; at the end of 1925 it contained 179,388 out of a total State population of 372,183.

With cultural institutions Perth is well supplied. In 1876 a boys' high school was opened with government assistance. In 1889 the public library came into existence to commemorate Queen Victoria's jubilee; the museum and art gallery, sections of the same memorial, were opened in 1895. The university was established in 1911 and opened in temporary buildings in 1913—it is gradually being transferred to a permanent home at Crawley. The first theatre—the Theatre Royal—was built in 1897, and His Majesty's Theatre soon afterwards; others were built later on. The principal concert-hall, Queen's Hall, is owned by the Methodist Church.

FREMANTLE, the seaport of Perth, dates from the arrival of the first immigrant-ship in 1829. During the course of that year nearly a score of ships arrived at Swan River, and the port assumed the proportions of a town more quickly than the capital itself. The first gaol was erected there in 1830, the first newspaper published in the colony was issued there in 1831, and the first horse-race run in 1833. A regular service of boats was soon established from

Fremantle through the capital to Guildford; though a bush-track between the port and Perth existed almost from the beginning of the colony, no definite road was made until 1845. In 1850 Fremantle became a landing-place for convicts, and most of the buildings required for the convict administration were erected there. Railway communication with Perth was established in 1881, in 1883 the town became a municipality, and its town-hall was opened in 1887. Harbour improvements were commenced in 1892, and in 1898 were so far complete that large steamers berthed within the mouth of the river. In 1906 electric tram and lighting services were initiated by the municipality. The town-hall and the Anglican, Roman Catholic, and Methodist churches have some architectural merit.

J.S.B.

Petalostigma, a genus of the family Euphorbiaceae, consisting of one species endemic in Australia, which ranges from New South Wales to Queensland and Western Australia. *P. quadriloculare* (Crab-tree, Native Quince, Emu-apple, Quinine Tree—all these names being shared by other plants) is a moderate-sized tree. The branches, under-sides of the leaves, and small, clustered flowers are clothed with loose silky hairs; fruit orange-coloured, ½ inch in diameter. The stem-bark contains a camphor-like essential oil, and a bitter principle—reputed to have properties like those of quinine—belonging to the glucosides. Brownish-yellow dyes made from the bark have been experimentally used for dying cotton and woollen fabrics. The hard, brownish wood resembles that of the English laburnum; its wavy grain gives it a pleasing appearance when polished.

Peter Peter. See FLYCATCHERS.

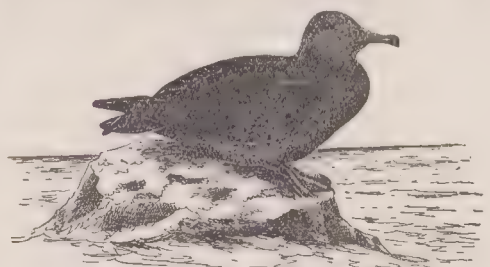
Pethebridge, SIR SAMUEL AUGUSTUS (1862-1918), born at Brisbane on 3 August 1862, educated at state schools in Brisbane and Townsville, and for a time privately, was sent as a boy for health's sake to Cape Bowling-green lighthouse, Queensland. Deriving thence a passionate love of ships, he entered in 1876 the Queensland ports and harbours department, and, subsequently joining the naval brigade of that State, served in the gunboats *Gayundah* and *Paluma* (lieutenant, 1894; commander, 1903). Upon the inauguration of the Commonwealth, being then secretary of the marine department of Queensland, he was chosen as the first chief clerk of the defence department, of which R. Muirhead Collins (afterwards official secretary to the high commissioner in London) was secretary and permanent head. When Collins went to London, Pethebridge succeeded him, and held that position at the outbreak of the war in 1914. He was in November 1914 appointed to command the expedition intended to take over from the Japanese the control of the Marshalls, Carolines, and Ladrones, formerly German possessions in the north-western Pacific. Just before the expedition sailed, a popular movement in Japan caused the government of that country to reverse its decision to give up the islands, and Pethebridge's force was accordingly diverted to the relief of the expedition which, under Colonel William Holmes, occupied German New Guinea. There Pethebridge succeeded Holmes as administrator (colonel, 1914; brigadier-general, 1916) and, until his death on 25 January 1918, largely moulded the policy of the Commonwealth government in relation to the occupied territory.

C.E.W.B.

Petrels, marine birds of the families Hydrobatidae, Procellariidae, and Pelecanoididae, which with the albatrosses (Diomedeidae) constitute the order Tubinares. Members of this order are found throughout the world, and are specially numerous in the southern hemisphere.

Petrels are exclusively oceanic birds; though some do not travel very far from shore, the majority range throughout great areas of ocean. At the breeding-season they assemble in great numbers on islands, excavating burrows in the ground, or selecting crevices among rocks in which the hen-bird lays a single white egg. When at the breeding-grounds they are almost entirely nocturnal; during the day-time one bird may be found in each burrow, but as darkness falls their mates begin to arrive from the sea—throughout the night there is a constant coming and going, the air over the colony being full of birds, while those in the burrows as well as those in flight utter curious, mournful cries. When dawn appears, half the birds leave again for the sea, and silence reigns once more.

By far the best-known of Australian petrels is the Short-tailed Shearwater (*Puffinus tenuirostris*)—commonly known as Mutton-bird—which breeds in immense numbers on the islands of Bass Strait and off the coasts of Tasmania, Victoria, and South Australia. Flinders calculated that a flock seen by him in Bass Strait, contained 132 million birds. The population of Cape Barren Island is entirely dependent on mutton-birds for its livelihood; over half a million young birds are collected annually and salted for food, the great majority being sent to Melbourne and Sydney for sale. The Bass Strait mutton-bird is a sooty-brown petrel of moderate size. Several other species with similar coloration and habits occur on other parts of the Australian coast-line, though at present they are not utilized for food. All the mutton-birds are members of the genus *Puffinus* and of the family Procellariidae. Other members of the



Mutton-bird (*length* 14 *in.*).

same family that breed on the Australian coast are the White-winged Petrel (*Pterodroma leucoptera*), which nests beneath the tangled scrub vegetation on Cabbage-tree Island in Port Stephens, and the little gray-blue Dove-petrel (*Prion turtur*), which nests in crevices among rocks on the islands of Bass Strait. Others, again, are seen in Australian seas chiefly during the winter, though their breeding-grounds are farther to the south. Of these the Giant Petrel (*Macronectes giganteus*) is nearly as large as an albatross. This species is usually of a uniform sooty-black colour, but some individuals are almost entirely white; yet they are not albinos,

since their eyes are of the normal colour and they generally have a number of dark feathers scattered through their plumage. The white form is rare in Australian seas, but becomes commoner towards the Antarctic continent. Another petrel of this family, familiar to voyagers, is the so-called Cape Pigeon (*Daption capense*), whose chequered black-and-white plumage is unlike that of any other bird.

Of the Hydrobatidae (storm-petrels, Mother Carey's chickens) several species occur in Australian seas, but only one, the White-faced Storm-petrel (*Pelagodroma marina*), is known to breed within their limits. There is a large colony of these little birds on Mud Island in Port Phillip, and other colonies inhabit islands along the southern half of the Australian coast.

The diving-petrels (Pelecanoididae) are represented in Australian seas by a single species (*Pelecanoides urinatrix*), which breeds among rocks on the islands of Bass Strait and Tasmania.

W.B.A.

Petrie, ANDREW (1798-1872), born in Fifeshire, Scotland, in June 1798, was induced to migrate to New South Wales in 1831 on the representations of Dr. Lang (q.v.). He worked in Sydney as a civil engineer, and in 1837 was sent to Moreton Bay as government superintendent (clerk of works), travelling by the *James Watt*, the first steamer to enter what are now Queensland waters. He subsequently became the builder of a large portion of early Brisbane. In 1838, while on an excursion with Major Cotton, the commandant, Petrie and his companions were lost for three days near the present Mount Petrie. In 1842 with Henry Stuart Russell and others he took the first boat along the Mary River and rescued two 'wild' white men—James Bracefield or Bracefell (the blacks called him Wondi, 'great talker'), and a still more remarkable personality, James Davis (Duramboi, 'kangaroo-rat'), a Scot who had escaped from the penal settlement at Moreton Bay as a lad 13 years old, and lived with the aborigines for 16 years. The farewelling of Davis by the blacks on his return to civilization constitutes one of the most dramatic of minor episodes in Australian history; Russell (*Genesis of Queensland*, pp. 284-5) records that when Davis embarked blacks appeared from behind every tree and wailed piteously, while Davis stood quivering in the boat and shouting them a promise to return in three months—'when the moon has come back to you three times, I shall be here.' (See WILD WHITE MEN.) Petrie (in 1838) was the first to discover the bunya-bunya pine (see PINES), which according to Russell was in Brisbane named *Pinus Petriana*. J. C. Bidwill (q.v.) afterwards brought in the first seedlings and sent them to Kew Gardens, London, where they were classified as belonging to the genus *Araucaria* and officially named *A. Bidwilli*. For the last 24 years of his life Andrew Petrie was blind; he died at Brisbane in February 1872. Petrie's Bight on the Brisbane River is named after him.

A.H.C.

Petrie, THOMAS (1831-1910), best-known son of the above, was born in Edinburgh and brought when three months old to New South Wales. From early childhood Petrie fraternized with the aborigines and learned to speak their languages; ultimately he became well known to thousands of wild blacks and was granted privileges extended to no other man outside the tribes. He frequently prevented conflict between whites and blacks, having firm faith in the goodwill and reliability of the aborigines if kindly treated; and sometimes alone, sometimes with Davis, he did valuable work in opening up tracks through the ranges. He was the only white man (except a few escaped convicts like Bracefield and Davis) allowed to be present at feasts of the bon-yi (bunya nut); when a boy of 14 he 'went bush' with a tribe for a fortnight on one of these picturesque picnics. Gifted with a remarkable memory for detail, in his later years he related his experiences with the aborigines, and a wealth of information concerning their customs, to his daughter Constance, by whom they were published as *Tom Petrie's Reminiscences* (Brisbane, 1904). Further information relating to the work of the Petries will be found in H. S. Russell's *Genesis of Queensland* (Sydney, 1888).

Petroleum. See OIL.

Petrophila, a genus of the family Proteaceae, consisting of extra-tropical shrubs, endemic in Australia and mostly in its western areas. The flowers are white or yellow, collected in cone-like heads; corolla regular, tube slender and separating into 4 petals from the base; anthers free, the connective produced into a small appendage; style surmounted by a brush; fruit a compressed nut, with a tuft of long hairs on the margin enclosed in the persistent woody cone-scales; leaves rigid, entire or divided, flat or cylindrical, and often charmingly decorative.

Phalangers. See OPOSSUMS.

Phanerogams. See BOTANY.

Phaseolus, a genus of the family Leguminosae, consisting of dwarf or twining annuals or perennials, widely distributed in warm regions. Three species are indigenous to Australia, *P. vulgaris*, *P. truxillensis*, and *P. mungo*; the last has yellow flowers, and is known as Green Gram or Mung-bean—names given to it in India, where it has long been cultivated and used as food for man and beast. The flour of the green variety has been used in that country as a substitute for soap. *P. vulgaris* is the French or Kidney Bean of the kitchen-garden.

Phasmidae. See STICK-INSECTS AND LEAF-INSECTS.

Pheasant, Mountain and Native. See LYRE-BIRDS and MOUND-BIRDS.

Pheasant, Swamp. See CUCKOOS.

Phebalium, a genus of the family Rutaceae, consisting chiefly of shrubs with small white or yellow flowers and leaves often clothed with scurfy scales. With the exception of one species in New Zealand, the genus is endemic in Australia. The calyx is 5-toothed; petals 5, with inflexed tips; stamens 10. *P. Billardieri* is a handsome shrub (occasionally a small tree); its leaves are covered on the under-side with minute silvery scales, and its small flowers, produced in pyramidal sprays, make a fine display. It grows in brush gullies, but readily adapts itself to ordinary garden conditions. Its timber somewhat resembles that of red cedar, but is of greater density and lighter colour. *P. dentatum* is an ornamental shrub, with clusters of small yellow flowers, and narrow leaves with blunt teeth on the margin. All species contain a more or less acrid oil; *P. argenteum*, a tall shrub

from south-western Australia, secretes this in such profusion that it is known locally as 'blister-plant.'

Philately. In 1837 Rowland Hill published in England a pamphlet showing that the average cost of conveying a letter or newspaper in Great Britain was about 1½ pence. A copy of this pamphlet reached New South Wales shortly after, and on 7 September 1838 James Raymond, then postmaster-general, wrote to the New South Wales colonial secretary in the following terms:—'Having attentively perused the suggestions of Mr. Rowland Hill on the subject of introducing stamped covers as a means of simplifying and effecting a reduction in postage, I have endeavoured to perfect an envelope which I do myself the honour to submit for the inspection of His Excellency the Governor.' Raymond's plan was to sell to the public at 1d. each sheets of paper impressed with the seal of the general post-office; a letter written on one of these sheets could be folded and sealed, and would then be passed through the post-office for distribution within the town delivery of Sydney, free of any other charge. As the town postage-rate was at that time 2d., Raymond's proposal was to reduce the postage by one-half and supply paper free. Governor Gipps minuted the paper 'Let the experiment be tried, but the price must be fixed at 1½d. the single cover, or 1s. 3d. per dozen.' The public were informed of the adoption of the stamped cover by *Gazette* notice dated 1 November 1838. New South Wales therefore put into practical operation the two great principles of Rowland Hill's reform nearly two years before Britain issued the first adhesive stamp and stamped envelopes (May 1840). In January 1841 the price of the New South Wales letter-sheet was reduced to 1s. per dozen or 8s. per 100; these postal conveniences remained in use until the issue of adhesive postage-stamps and the introduction of compulsory prepayment of postage in 1850.

These innovations were authorized on 12 October 1849. Little time was available for preparing dies for the postage-stamps, but Raymond obtained from local engravers tenders for engraving plates. The work was eventually entrusted to three artists, Robert Clayton furnishing a copper plate containing 25 engravings of a penny stamp, John Carmichael a copper plate containing 24 engravings of the twopenny stamp, and H. C. Jervis a copper plate containing 25 engravings of the threepenny stamp. From these plates a supply of stamps was printed by Charles Kay of Union-street, Sydney, under the supervision of a board consisting of the auditor-general, the colonial storekeeper, and the postmaster-general. The stamps, gummed and ready for use, were issued to the public in time for employment in prepaying postage on 1 January 1850. The design adopted for all three values was an adaptation of the reverse of the colonial seal (see SEALS AND ARMORIAL BEARINGS), the original medallion for which had been modelled by Josiah Wedgwood in clay sent to him from Australia. Collins (*Account of the English Colony in New South Wales*, 1804) describes the reverse of the seal as 'a representation of convicts landing at Botany Bay, received by Industry, who, surrounded by her attributes—a bale of merchandise, a beehive, a pickaxe, and a shovel—is releasing them from their fetters, and pointing to oxen ploughing, and a town rising on the summit of a hill, with a fort for its protection. The masts of a ship are seen in the bay.' The inscriptions were '*Sigillum Nov. Camb. Aust.*' with the motto '*Sic fortis Etruria crevit*' beneath the central design.

The penny stamp was printed in red; the twopenny in blue, and the threepenny in green.

Early stamp-collectors (1860-2) imagined that the design of these stamps represented a view of Sydney, and that they were used only for local postage. They were termed 'Sydney Views,' and are still colloquially known by that name. The issue enjoyed a brief existence, being replaced in 1851-2 by stamps bearing a portrait of Queen Victoria with a laurel wreath; this series is known as the 'laureated' issue, and consisted of the same denominations as the first issue with two additional values—sixpence, and eightpence, printed in brown and yellow respectively. The plates of the 1d., 2d., and 3d. were of steel, containing 50 engravings each. The 6d. and 8d. plates were of copper, the former containing 25 and the latter 50 engravings. John Carmichael engraved the first four values, and H. C. Jervis the 8d.

These two issues have long held the highest place in the esteem of philatelists, not only on account of their quaint designs, rich colouring, and comparative rarity, but because there are as many varieties of type as there were engravings on a plate—the most skilful engraver cannot exactly reproduce any design in hand-engraving. In 1865 Edward L. Pemberton published an article describing and differentiating the main varieties of the 1d. and 2d. Sydney Views; during 1867-9 he published other articles showing that many different plates had been engraved. In 1878 Dr. Legrand proved that there were two plates of the 1d., each containing 25 types, the first plate being described as 'without clouds' and the second 'with clouds' (the 'clouds' were lines of shading in the space above the 'view'). M. P. Castle in 1884 described five plates of the 2d., and arranged them in the correct order of issue. In 1887 T. K. Tapling in collaboration with Judge F. A. Philbrick reconstructed all the plates of the Sydney Views from single stamps, pairs and blocks; the 1d. plate, they found, contained 25 types, arranged in five horizontal rows of five stamps. This plate, however, had been entirely re-engraved, the position of the stamps remaining relatively the same, but the details of the design being so altered, as, together with the insertion of 'clouds,' to constitute an easily distinguishable group of 25 types. The 2d. plate was found to contain 24 types arranged in two horizontal rows of 12 stamps; engraved at first with vertical lines in the spandrels, it was at an early date re-engraved, the lines being horizontal. Three subsequent re-engravings of the same plate were all reconstructed, each showing features common to every stamp on the plate, but differentiated from the preceding or following plates. The 3d. plate was shown to contain 25 types arranged in five rows of five, as in the case of the 1d. This plate was not re-engraved. Further, the authors listed and described the numerous varieties of paper on which the various plates were printed, and the shades of colour associated with each plate and paper. These results were published by the Philatelic Society of London in its catalogue of the *Stamps of Oceania* (1887), accompanied by autotype illustrations of the reconstructed plates. Subsequent investigations by Dr. Houison and A. F. Basset Hull (who had the advantage of access to official records in Sydney) established beyond all doubt the accuracy of the work of the European philatelists.

For the Laureated series Tapling and Philbrick correctly reconstructed the plate of the 1d.; showed that there were two plates of the 2d., one steel and the other copper, and that the steel plate was wholly re-engraved, all three plates being reconstructed; correctly placed the 50 types of the 3d. plate; showed that there were an original and a re-engraved plate of the 6d.; and, with one or two errors in relative position, reconstructed the plate of the 8d. Years later the original plates of the 2d. (copper), 6d. and 8d. were discovered, and impressions taken from them showed the correctness of Tapling and Philbrick's arrangements, with slight discrepancies in the 8d.

The locally engraved and printed stamps of New South Wales included also a registration label, produced in two colours from two steel plates—one of the central portrait of the Queen, and the other of the inscribed label—engraved by John Carmichael; there were 50 stamps to the plate, all varying in minute detail. This plate also was reconstructed by Tapling and Philbrick, the subsequent discovery of the original plate showing that only two stamps had been misplaced. Registration stamps were first issued in 1856, and the distinctive stamp was withdrawn in December 1867.

The method of producing stamps by hand-engraving on copper or steel plates was unsatisfactory for two reasons—first, the impossibility of uniform reproduction of design, second, the slow process of printing from small plates. Steps were taken early in 1852 to obtain from England steel plates containing mechanically reproduced impressions, and in February 1854 stamps of 6d. and 1s. were printed in the colony from plates engraved by Perkins, Bacon & Co. of London. During the two following years additional values of 1d., 2d., 3d., 5d., and 8d. were issued. The three lower values were of the ordinary size, but the higher values were large square stamps of ornate design and elaborate engraving; all bore a portrait of the Queen in profile, wearing a diadem. This series is known as the 'Diadem' issue, and its philatelic interest is largely due to the fact that it was first issued imperforate, and was subsequently perforated. The paper on which these stamps were printed bore as watermarks double-lined figures corresponding to the value of the stamp printed thereon. This safeguard against forgery had been initiated early in 1854, the three lower values of the laureated series having been printed on paper watermarked with the figures 1, 2, and 3; in printing the diadem series, paper with the appropriate watermark was used until a shortage occurred, and then some printings of the 2d., 6d., and 1s. were made on paper designed for other values—the 6d. with watermarks 5, 8, and 12, the 2d. with watermark 5, and the 1s. with watermark 8. These varieties are not errors—they were officially authorized as emergency printings. On the other hand there are three varieties of watermark which, from their extreme rarity and the fact that no record of their authorization can be found, may properly be classed as errors. These are the 2d. with watermark 1 and 8, and the 3d. with watermark 2. Probably only one sheet of each was printed.

The designs of the square stamps were adapted from sketches supplied by S. Levinge, a clerk in the Sydney post-office. When in 1859 it was proposed to provide a 5s. stamp, Levinge prepared a highly ornate design, and expressed a hope that the design would be adhered to, however much the drawing might be improved upon. The engraving was entrusted to Perkins, Bacon & Co., who produced a beautiful die, but transformed a waratah into a combination of the rose, shamrock, and thistle. The 5s. stamp was printed in the colony from the steel plate engraved in England, and was issued in 1861. In the same year an electrotype die and plate for printing 2d. stamps were ordered from De la Rue & Co., London, and the first supply of stamps was printed, gummed, and perforated by the engravers; later supplies were produced at the government printing-office at Sydney. This value was followed by others at intervals, denominations of 1d., 4d., 10d., 6d., and 1s. appearing between 1864 and 1876. The steel dies were in each case engraved by De la Rue & Co.; and the first plates of the three first-mentioned values and the 1s. were sent out with the dies. The 6d. plate was made at the government printing-office at Sydney. Subsequent issues for New South Wales were engraved in the colony, and printed from locally made electroplates at the government printing-office. A temporary issue of high-value stamps was made in 1885, the long rectangular 'Stamp Duty' stamps of 5s., 10s., and £1 (engraved by De la Rue & Co.), being overprinted with the word 'POSTAGE,' issued primarily for prepayment of telegrams, and subsequently pressed into general postal use.

In 1888 the centenary of the colony was commemorated by the issue of a new series of postage-stamps. The designs were selected from a number sent in by local artists in response to an advertisement issued by the postmaster-general. The dies were engraved and the electroplates prepared by the government printer at Sydney. Each of the 'Centennial' stamps bore a different design, although the words 'One hundred years' were common to all.

With the introduction of universal postal union rates at the end of 1890, it became necessary to provide several new denominations. For the 2½d. value a die and plate were engraved by the government printer, the design being symbolical of the world-wide ramifications of the union; the other values were produced by printing from the recently obsolete De la Rue plates in distinctive colours, with the new denomination indicated by an overprint in black. The first surcharged stamp of this colony was the 9d. of 1871, which was made from the 10d. plate, printed in a different colour and overprinted 'NINEPENCE.' In 1897 a series of three stamps was issued to commemorate Queen Victoria's diamond jubilee; dies and plates were engraved at the government printing-office. A vote of philatelists gave this New South Wales 2½d. stamp the distinction of being among the ugliest in the world. In the same year special stamps were issued at 1s. and 2s. 6d., the difference between the postal value (1d. and 2½d. respectively), and the sale-price being devoted to the funds of the local hospitals. These were large stamps of highly ornate appearance, produced by lithography at the government printing-office.

Victoria. Although the Port Phillip district was not officially separated from the parent colony until 1 July 1851, distinctive postage-stamps bearing the legend 'Victoria' were issued in January 1850. The design consisted of a half-length portrait of Queen Victoria, holding the orb and sceptre. Dies for three values of 1d., 2d., and 3d. were engraved on a steel plate by Thomas Ham, a local engraver, who made lithographic transfers from the dies, and printed

the stamps by that process. The die of the 2d. was twice re-engraved in certain details of border or background, and these constitute the only types properly so called. In the process of making the transfers and laying them on the lithographic stones Ham and subsequent printers produced a number of varieties, resulting from defective impressions, repairs, etc., all of which have been described in detail by philatelic writers. The 'half-length' series was followed in 1852 by a larger 2d. stamp, bearing a full-length picture of the Queen on a throne, with the value in words beneath; the name of the colony was omitted. The plate was engraved by Ham on copper, and contained 50 stamps, all of which differed in type, there being a letter in each lower corner so arranged that no two stamps contained the same two letters. In 1854 stamps were lithographed from transfers made from this plate. In 1854-5 two stamps for special service were issued, one for registered letters, value one shilling, and the other for too-late letters, value sixpence; these were engraved locally on boxwood by Samuel Calvert, and printed in two colours. In 1854 ordinary postage-stamps of 6d. and 2s. were engraved and printed by Calvert, and a 1s. stamp of small octagonal shape was lithographed by Campbell and Ferguson. In 1856 two steel plates were engraved by Perkins, Bacon & Co. of London, the design being 'Queen on Throne' with the name of the colony above; the values were 1d. and 6d., and a supply of stamps was printed on paper watermarked with a star, and sent out with the plates—which, however, were never used for printing in the colony. A series bearing a portrait of the Queen in profile, with sheep, a ship, and other emblems of colonial industry in the corners, known as the 'Emblems,' was engraved and printed from electroplates by Calvert Brothers of Melbourne.

Numerous issues followed, the dies being engraved locally and electroplates made at the government printing-office, with two exceptions; these were the laureated series of 1863-4, the plates of which were made by the government printer at Sydney, and the 2d. of 1870, the die of which was engraved by De la Rue & Co. in London. In 1885 stamps formerly issued for payment of stamp duties were rendered available for postage, and a new series of stamps from ½d. to 1s. 6d. was issued, bearing the inscription 'Stamp Duty,' but available for both postal and fiscal purposes.

In 1853 *Tasmania* issued postage-stamps, two plates for values of 1d. and 4d. being engraved on copper by C. W. Coard, and printed at the *Hobart Town Courier* office on unwatermarked paper. These were quaint designs, having a small profile of the Queen in the centre, surrounded by the name 'Van Diemen's Land' and the value in words. The 1d. was rectangular with hollowed corners, the 4d. octagonal. Of the higher value two plates were engraved, differing slightly in detail. All three plates contained 24 types which are easily plateable. These were followed in 1855 by handsome stamps of 1d., 2d., and 4d., engraved on steel and printed from steel plates by Perkins, Bacon & Co. of London on paper watermarked with a star. The plates were sent out with the English-printed stamps, and thereafter supplies were printed locally, first on unwatermarked paper and later on paper specially manufactured in England bearing watermarks of figures corresponding with the values. In 1856 the name of the colony was changed to 'Tasmania,' and two new stamps of 6d. and 1s. were engraved on steel by the London firm, supplies printed on paper watermarked 6 and 12, being sent out with the plates, from which supplies were subsequently printed locally. There were thus five denominations in use up to 1870, three bearing the old and two bearing the new name of the colony. Although the issues up to 1869 were unperforated, many firms had their sheets perforated or rouletted; a number of varieties of these unofficial perforations exist. In 1870 De la Rue & Co. of London were commissioned to prepare electroplates for stamps of 1d., 2d., 4d., and 10d.; these were sent out to the colony, and supplies were printed from them on paper, borrowed from New South Wales, bearing small figures of value as watermarks. Later a paper was imported bearing the letters 'T A S' as a watermark, and values of 3d., 9d., and 5s. were added. In 1878 the 1d. and 2d. stamps, together with a new value of 8d. were procured from De la Rue & Co. The postal union rates necessitated the adoption of two new values in 1889-91, and ½d. and 2½d. stamps were produced by overprinting those values on the 1d. and 9d. stamps respectively. A permanent ½d. die and electroplate were procured from Victoria, and the stamps were printed locally. In 1892 a new design was adopted, having a small portrait of the Queen in ornamental frame as a 'key' plate for all values, with the denomination printed in a cartouche in another colour. This series of ten values from ½d. to £1, was electrotyped and printed by De la Rue & Co. In 1896 a handsome set of pictorial stamps was issued, printed from engraved plates by De la Rue & Co.; these were of large size, and illustrated some of the most beautiful island scenes. Later, supplies were printed in the colony, both from the English-made plates, and from local zincograph reproductions.

In 1879 postal and fiscal stamps were made available for either purpose, and fiscal stamps of 1863 (with a design of St. George and the Dragon, copied from the sovereign) were authorized for postal use, as well as the 'stamp duty' series, engraved and printed by De la Rue & Co., which had for design a platypus on the bank of a stream.

Western Australia issued its first postage-stamp in August 1854; it was engraved on steel by Perkins, Bacon & Co., the design being a swan swimming to the left in an oblong inscribed frame. The first supply was printed by the engravers in black. New values of 4d. and 1s. were made in the colony by the government printer, who took lithographic transfers of the swan, and enclosed it in an octagonal frame for the 4d. and an oval frame for the 1s. A transfer of the 4d. had the frame inverted; a few of these stamps, known as the 'Inverted Swan,' are still in existence, and as much as £800 has been paid for a used specimen. Two more values, 2d. and 6d., were lithographed at the government printing-office in 1857, and in 1860 printings were locally made from steel plates engraved in London, of 2d., 4d., and 6d. denominations. The local efforts not being deemed altogether satisfactory, Perkins, Bacon & Co. were commissioned to print supplies up till 1864; the contract was then transferred to De la Rue & Co., who printed from Perkins, Bacon & Co.'s steel plates for many years. In 1872 a new value of 3d. was added, the die and electroplate being made by De la Rue & Co. Between 1885 and 1893 the steel-plate stamps were gradually superseded by De la Rue's electrotyped stamps—bright-coloured prints with design of a European swan. In

this colony, also, revenue stamps were authorized for postal use, and the two telegraph-stamps were also utilized.

The first postage-stamps of *South Australia* were issued in January 1855. They were engraved on steel by Perkins, Bacon & Co., the design consisting of a diademed portrait of the Queen on an engine-turned background. These stamps were first printed by the engravers on paper watermarked with a large star; the colours were very rich, and the stamps were issued imperforate. Later supplies were printed in the colony and issued imperforate, rouletted, and perforated in successive years. The English-printed values were 1d., 2d., and 6d. Plates for 1s., 4d., 9d., and 2s. values were subsequently supplied, and stamps were printed therefrom in the colony. New values were created by using different colours and overprinting the 9d. 'TEN-PENCE,' the 4d. '3-PENCE,' and the 9d. '8-PENCE.' The steel-plate stamps were to some extent superseded by an issue engraved and electrotyped by De la Rue & Company, and printed in the colony on paper watermarked with a crown over the letters S.A. In 1887-93 stamps of new types inscribed 'Postage & Revenue,' were issued for both postal and fiscal use. The series ranged up to £20, and the denominations from 2s. 6d. upwards were large rectangular stamps with a portrait of the Queen in the centre. In 1894 two stamps were designed by Tannenberg of Melbourne, and the plates made by Sands & McDougall of that city. The values were 2½d. and 5d., the designs comprising a small portrait of the Queen, and (*a*) a kangaroo (2½d.), (*b*) the colonial arms (5d.).

Queensland was the last of the colonies to issue postage-stamps. Separated from New South Wales by an order-in-council dated 6 June 1859, the 'Moreton Bay district' was erected into a colony; but the stamps of New South Wales were purchased at cost of printing and issued by the postal department of the new colony until distinctive stamps could be procured from England. Perkins, Bacon & Co. engraved the dies and prepared the steel plates, printing the first supplies of 'Queensland' stamps on star-watermarked paper; these consisted of 1d., 2d., 3d., 6d., 1s., and registered stamps, the design being an elegant full-face portrait of Her Majesty in an inscribed oval with engine-turned spandrels. The plates were sent out with the stamps, three values being issued in 1860, and subsequent supplies were printed in the colony on both plain and variously watermarked papers. In 1866 two new values, 4d. and 5s., were produced by lithography from impressions from the steel dies of 3d. and 1s. The alterations in the values were made by hand on the stone, and there are many varieties in the lettering. In 1879 a die for producing electrotypes was engraved by W. Bell of Sydney, electros were made by W. Knight of the government printing-office at Brisbane, and from these 1d. and 2d. stamps were printed. The design was a crude profile portrait of the Queen in inscribed oval. Owing to the primitive means at Knight's disposal, the electros were prepared in groups of four, showing varieties of type and lettering. These two stamps were followed by 4d., 6d., and 1s. values of the same design. In 1881 more high values (2s., 2s. 6d., 5s., 10s., and 20s.) were produced by lithography from transfers from the original 1s. die. These stamps were available for both postal and fiscal use. In 1882 a steel die for a 2d. stamp was procured from Bradbury, Wilkinson & Co. of London. From this die electroplates for 1d., 2d., 4d., 6d., and 1s. values were prepared by Knight, the plates being made up of groups of four as in the previous issue; numerous varieties of type exist. In the same year a set of five steel plates was procured from the same English firm for printing the values from 2s. to £1. The stamps were of strikingly handsome design and elaborate execution, the full-face portrait of the 1860 stamps being repeated, and the remainder of the design consisting of inscriptions, figures of value in each corner, and fine ornamental details of engraving; the colours also were rich. During 1887-1900 values of ½d., 2½d., and 5d. were added, and several alterations in the general design of the other values were made, figures of value being added in the angles, and the shaded background being removed from the central portrait.

With the issue of the postage and revenue high values in 1881 the then current 'stamp duty' series was authorized for postal use, and advantage was taken of the opportunity to use up for postage any unused examples of the obsolete duty-stamps.

When in 1901 all postal and telegraphic services were transferred to the Commonwealth, the distinctive State stamp-issues were still retained, as this facilitated the working of a clause in the constitution which provided that for ten years the accounts of the six States must be kept separately. Stamps were issued through the Commonwealth post-offices, but as a rule each State printed its own, and the stamps of any one State were not valid in another. Two stamps, value 9d., were issued with the inscription 'Commonwealth,' but each bore in addition the name of the State (New South Wales or Queensland) for which it was valid. In 1912, however, the statutory period having elapsed, stamps of any State were made valid throughout Australia, and it became possible to use, say, Victorian stamps to frank letters from Queensland to Western Australia; collectors took a delight in making varied combinations to illustrate the validity of all issues everywhere.

In January 1913 appeared the first general Australian issue, engraved locally and printed from electroplates at the government printing-office in Melbourne—the design being an outline map of Australia on a shaded background, with a kangaroo in the centre. The series comprised 15 denominations ranging from ½d. to £2, the four highest values being printed in two colours. Exception was taken to the design in some quarters because it did not follow the usual colonial pattern by including the head of the reigning monarch; consequently in December 1913 (a new ministry having come into power) a penny stamp was issued bearing the head of King George surrounded by wattle-blossom, with a kangaroo and an emu at the sides. The first issue (one million) was printed from an engraved steel die, and to prevent speculation among collectors it was ordered that no buyer should be supplied with more than six; enterprising collectors visited all the offices within reach and secured a quota at each, so that the restriction effected little. It was intended to extend this series through all existing denominations, but a second change of ministry and the outbreak of war put an end to all ambitious plans, and the only other steel-engraved issue was a 6d. stamp bearing a kookaburra. The new penny stamp was afterwards issued with a slightly altered design printed from electroplates, and ½d., 1½d., 2d., 2½d., 4d., 4½d.,

5d., and 1s. 4d. stamps of the same design followed, but for all other values the kangaroo type still stands.

In the history of Australian philately probably the most important events have been the donations by Henry Luke White (q.v.) of Belltrees to the Mitchell Library in Sydney; in June 1917 he gave his New South Wales collection, and in 1923 his collections of Queensland, Tasmanian, and Western Australian stamps, a moderate valuation of the whole being £30,000.

See Basset Hull's *Stamps of Tasmania* (1890) and *Postage Stamps of New South Wales* (1911), and Houison's *History of the Post Office* (1890). Of the many philatelic journals the *Australian Philatelist* is probably the most informative. It has recently ceased to exist, but the *Australian Stamp Journal* is still current. A.F.B.H.

Phillip, ARTHUR (1738-1814), born in London on 11 October 1738, was trained for the naval service at Greenwich, in 1753 was apprenticed aboard a ship trading to Greenland, and in 1755 joined the navy (midshipman, 1755; lieutenant, 1762; commander, 1779; captain, 1781; rear-admiral, 1801; vice-admiral, 1809). He saw service in the Mediterranean with Byng's disastrous expedition, and also in the West Indies, particularly at the capture of Havana. In 1763 he went on half-pay, and farmed land in the outskirts of the New Forest. When war broke out between Spain and Portugal in 1774 he offered his services to Portugal, and during the next four years earned encomiums from the Portuguese government; the outbreak of the war with France in 1778 brought him back to England, and to service with various squadrons in British and East Indian waters. In 1784 he was again on half-pay, but in 1786 was chosen by Lord Sydney—then secretary of state for the home department—to lead the expedition destined for Botany Bay.

The reason for this choice is not clear—Howe, the first lord of the admiralty, was captious about it—but its justification was complete. On 24 October 1786 Phillip hoisted his flag as commodore in H.M.S. *Sirius*, and from that moment devoted himself wholly to assuring the success of the expedition. No detail was too small, nor was any suggestion too vague, to escape his close attention; every difficulty which he propounded to his superiors was accompanied by a proposal for its solution. The *Historical Records of New South Wales* (vol. 1, part ii) include a mass of letters and memoranda wherein, among notes about saddles for explorers and grindstones and small tin lamps for presenting to native chiefs, there occur at intervals such aphorisms as:—

> I would not wish convicts to lay the foundations of an empire. . . . The laws of this country will, of course, be introduced in [New] South Wales, and there is one that I would wish to take place from the moment his Majesty's forces take possession of the country: That there can be no slavery in a free land, and consequently no slaves.

His solution of the capital punishment problem is also noteworthy: 'I would wish to confine the criminal till an opportunity offered of delivering him as a prisoner to the natives of New Zealand, and let them eat him. The dread of this will operate much stronger than the fear of death.'

On 12 May 1787 the 'First Fleet,' which had been assembled off Portsmouth, set sail and passed the Needles bound for New South Wales—which appeared on Phillip's chart as New Holland. The fleet consisted of H.M.S. *Sirius* (on which Phillip had John Hunter as 'second captain'), H.M. armed brig *Supply*, the transports *Alexander, Scarborough, Charlotte, Friendship, Lady Penrhyn,* and *Prince of Wales,* and the victualling ships *Borrowdale, Golden Grove,* and *Fishburn,* carrying provisions, tools, and equipment. On arrival at Botany Bay Phillip was to take up the office of captain-general and governor-in-chief of New South Wales; he had on his ship, as lieutenant-governor designate, Major Robert Ross in command of 197 marines. The outward voyage is described under FIRST FLEET. Phillip in the *Supply* (to which he had transferred himself) reached Botany Bay on 18 January 1788, and went ashore on the northern side immediately on arrival. He was met by a party of armed natives, who responded to his signs of friendship by throwing down their weapons and accepting presents of beads and red baize. An examination of the bay, with its low-lying and marshy shores, convinced him that it was unsuitable for a settlement. Accordingly he placed Ross in charge there, and on 22 January, taking Hunter and other officers, set out on a boat-expedition to examine Port Jackson—which had been named by Cook as he sailed along the coast, and described in his journal as 'a bay or harbour in which there appeared to be a good anchorage.' Examining the several coves as rapidly as possible, Phillip fixed upon one which had the twofold advantage of deep water close to the shore and a running stream of fresh water. This he named Sydney Cove. He returned to Botany Bay on 24 January and saw to his astonishment two ships under the French flag beating up off the mouth of the bay. They proved to be the *Boussole* and the *Astrolabe* on a voyage of discovery under the command of La Pérouse (q.v.). Phillip, however, was in a hurry to get back to Port Jackson, and left the visitors to be dealt with by Hunter and King; he himself went on board the *Supply* and took her round to Port Jackson on 25 January, leaving Hunter to follow with the transports on the morning of the 26th. On that day a party was landed in Sydney Cove, the British flag was unfurled, toasts were drunk, and volleys fired. The formal proclamation of the colony did not take place until 7 February.

Poor soil and inefficient labour hampered Phillip in his efforts to make the settlement self-supporting. Writing to Evan Nepean, the under-secretary to the admiralty, he declared that 'if fifty farmers were sent out with their families they would do more in one year to render the colony independent of the mother country than a thousand convicts.' That letter contained the first suggestion for the importation of free emigrants. At first Phillip lived in a canvas house which he had brought out with him; afterwards a stone house was built for him on a site now in Bridge-street. Brick houses were constructed for the officers, log huts, plastered, for the convicts, and barracks for the soldiers; a hospital was also built.

From the outset Phillip was confronted with the food-problem. On 14 February he sent Lieutenant King in the *Supply* with a party of soldiers and convicts to form a settlement at Norfolk Island, which had been discovered by Cook; during the voyage Lieutenant Ball, in command of the *Supply,* discovered a small island 440 miles east of Sydney, named it Lord Howe Island, and annexed it to New South Wales—of which it is still a dependency. The settlement of Norfolk Island left Phillip with

fewer mouths to feed in Sydney, but on the thickly-wooded shores of Port Jackson he found no land suitable for cultivation. In quest of cultivable land he sailed along the coast to Broken Bay (q.v.) in March 1788; he expected to find a great river flowing into it (as indeed there is), but heavy rains compelled him to return to Sydney Cove without penetrating the estuary. His other exploring journeys are described under EXPLORATION BY LAND. But little land of agricultural value was discovered, the convict labourers were indolent and sometimes recalcitrant, and the spectre of famine appeared in the first year of the settlement. In June the few head of cattle strayed and were lost; most of the other imported live stock were already dead; this was possibly no great loss, as in September Phillip reported that the colony was not in a state to support any considerable quantity of live stock, and that his supply of seed-wheat for the coming year was miserably deficient. From that time to the arrival of the transport *Lady Juliana*, followed by the *Justinian*, in June 1790 famine was always impending. Phillip cut down the rations of salt pork, flour, and rice—which in any case, having been brought out with the expedition, were almost unfit for food—and sent the *Sirius* to the Cape for provisions. She brought back a small quantity of flour, but narrowly escaped shipwreck on the voyage. He then determined to send her to China for food as soon as she returned with the *Supply* from Norfolk Island—but she never returned, being wrecked on the island. Hunter and the crew were saved. Rations at Sydney Cove were cut down for every man, including the governor. Phillip collected a party of convicts, provided them with muskets, and sent them out into the bush to shoot kangaroos—they shot three in three weeks. He sent other convicts to catch fish—but had to put armed guards in every boat to prevent the ravenous fishermen from eating their catch. He then sent Lieutenant Ball in the *Supply* to Batavia for provisions, and by her forwarded despatches to London apprising the British ministry of his desperate situation. The stock of provisions dwindled fast. The people grew so weak from want of food that they could not work, and several died of starvation. Phillip hung on grimly. On 3 June 1790—two months after the *Supply* had sailed—the *Lady Juliana* arrived from London with a cargo of flour and a consignment of prisoners. Her master reported that the 44-gun ship *Guardian*, with provisions and stores, had collided with an iceberg south of the Cape; Lieutenant Riou had navigated her back to Cape Town, and transferred his flour to the *Lady Juliana*. A fortnight afterwards the *Justinian* arrived with a full cargo of provisions, and the famine was over. The *Guardian* reached Sydney shortly afterwards with the transports of the second fleet.

Phillip's attitude towards the aborigines was well defined by Bradley: 'the Governor's plan with respect to the Natives, was, if possible, to cultivate an acquaintance with them without their having an Idea of our great superiority over them, that their Confidence and Friendship might be more firmly fixed.' Tench, commenting on the comparative failure of the plan, asserts that 'all ranks of men have tried to effect it, by every reasonable effort from which success might have been expected . . . in the higher stations this has been eminently conspicuous.' Phillip began by effecting in December 1788 the capture of a native named Arabanoo, whom he placed in his own house and endeavoured to train as an interpreter, but lost through smallpox in the following May just as he was beginning to be useful. In November 1789 two other natives, Colebee and Bennelong, were captured, but both escaped; in the summer of 1790 they were seen at Manly, and Phillip with Collins and Waterhouse went there by boat to parley with them. While he was speaking to Bennelong an old black named Willemering—who apparently thought that the whites were about to capture others of his people—advanced with threatening gestures towards Phillip, who continued to walk forward calmly. The black threw a spear; the barbed point struck Phillip above the collar-bone, and came out at his back; whereupon the party, being unarmed, retreated to the boat amid a shower of spears that luckily hit no one. Before Phillip could go aboard the shaft of the spear had to be broken off. When the party reached Sydney Cove, the assistant surgeon (Balmain) extracted the spear-head, which had missed the vital organs, and in six weeks Phillip had completely recovered. He refused to punish Willemering, but Bennelong and Colebee gave the offender a sound beating. Bennelong and another black, named Yemmerawanyea, accompanied Phillip when he left Sydney in December 1792. Yemmerawanyea died in England, but Bennelong returned to Sydney.

Phillip's wish to conciliate the natives proved unattainable. Tench—who was in favour of friendliness—ascribed the failure to the aboriginal temperament:—'they either fear, or despise us too much, to be anxious for a closer connection . . . the fickle, jealous, wavering disposition of the people we have to deal with.' The belief that some misbehaviour of La Pérouse's French crews had provoked hostilities he dismisses as absurd. It is probable that the natives' distrust of the whites—which occasionally developed into active hostility—was caused, as in so many other new European colonies, by mutual ignorance of national customs. The aboriginal view of property, especially of property in food-supplies, was not understood by the colonists, who must have trespassed repeatedly on native food-preserves; on the other hand the natives looked on sheep and cattle as varieties of kangaroo, and saw no harm in taking their share. In the end Phillip was driven—probably much against his will—to send out punitive expeditions in order to stop the murder of isolated working-parties (see DAWES, WILLIAM); but at the same time he strictly forbade all 'persons not expressly ordered out for that purpose, ever to fire on any native, except in his own defence, or to molest him in any shape.'

Among other details of administrative organization Phillip divided the settlement into four sections, appointed a night-watch, set up courts of civil and criminal jurisdiction, and made regulations for the maintenance of public order—which brought him into conflict with Ross. Always he kept firmly before him the need of developing agriculture, so that James Ruse (q.v.) was given a small grant of land at Parramatta, on which he 'sowed the first graines.'

Having established farms at Parramatta, conferred grants of land on various officers and settlers, and introduced the system of assigning the services of prisoners to holders of agricultural land, Phillip desired to return to England; but when he pleaded ill-health his resignation was accepted. On 11 December 1792 he embarked in the *Atlantic*, and on arrival in England in 1793 was awarded a pension of £500 in recog-

nition of his services. He died at Bath on 31 August 1814, and was buried in the church of St. Nicholas at Bathampton.

Phillip's cool, determined courage saved the infant settlement at Sydney Cove from being blotted out by starvation. By developing agriculture he made the settlement self-supporting. As an administrator he transformed a naturally disorderly mob into a sober and well-disciplined community. As an explorer he opened up fertile areas that enabled the colony to raise its own food. Australia owes much to officers of the British navy; to Arthur Phillip, a naval officer of the best type, she owes her very existence as a British community. See NEW SOUTH WALES.

Philp, SIR ROBERT (1851-1922), was born in Glasgow on 28 December 1851, brought to Queensland when ten years old, and educated at the Normal school in Brisbane. In 1863 he began a commercial career, and after 11 years' service with Bright Brothers migrated to Townsville and joined James Burns (q.v.) managing the Townsville business from 1877 onwards and in 1883 becoming a partner in the well-known firm of Burns, Philp and Company. In 1886 he entered politics and thenceforward devoted most of his time to them. As a supporter of Sir T. McIlwraith and his policy of making the northern areas of Queensland into a new colony, Philp won the Musgrave seat in 1886 and one of the two Townsville seats in 1888; the latter he held continuously until 1915. In 1893 he joined the Nelson ministry as secretary for mines and public works, and remained a minister under Nelson, Byrnes, and Dickson until the end of March 1899, holding at various times the portfolios of mines, works, public instruction, and railways, and eventually becoming treasurer; this office he held from March 1898 to December 1899, making his name as a straightforward and clear-thinking —if decidedly conservative—administrator. In December 1899 the first Labour ministry of Queensland held office for seven days; then Philp came back as premier for nearly four years, led the opposition from September 1903 to November 1908, enjoyed a short premiership from that month till the following February, and returned to opposition until November; he then formed a coalition with his rival William Kidston and, declining a portfolio, supported him and his successor Digby Denham as a private member until his defeat at Townsville in 1915. He then retired from politics, returned to commercial pursuits, and died at Brisbane on 17 June 1922. He was warden of the council of the university of Queensland from 1916 until his death. (K.C.M.G., 1915.)

Phosphate. See MANURES and MINERALOGY.

Phyllanthus, a large and widespread genus of the family Euphorbiaceae, consisting of trees, shrubs, or herbs with insignificant unisexual flowers. Thirty-nine species, ranging from east to west over warm regions, are indigenous to Australia. *P. Ferdinandi* (White Beech, Pencil Cedar, the 'tow-war' of the Queensland aborigines) is a medium-sized tree, with bronze-green leaves that turn red in autumn. The compressed fruit-capsules (known to children as 'cheeses') are ruddy and ornamental. The timber is close-grained and of a soft gray colour, and easy to work; it is used for staves, but warps somewhat in drying. *P. Gastroemi* is an ornamental shrub with slender, pendulous branches, whose oval leaves (arranged in pairs) impart a mimosa-like appearance to the foliage.

Pigeon, Blue. See CUCKOO-SHRIKES AND CATERPILLAR-EATERS.

Pigeon, Cape. See PETRELS.

Pigeons, birds of the order Columbiformes, which is represented throughout the world but is most numerous in the Australian region. About 25 species of pigeon occur in Australia, including representatives of three families—Columbidae, Turturidae, and Treronidae.

The first-named family contains only two Australian species, the White-headed Pigeon or 'Baldy' (*Columba norfolciensis*), and the Pheasant-tailed or Brown Pigeon (*Macropygia phasianella*)—both of them confined to the scrubs of eastern Australia.

Of the 15 Australian species of Turturidae, all but one are peculiar to Australia, the exception being the Green-winged Pigeon (*Chalcophaps chrysochlora*), whose range includes eastern and northern Australia and the Moluccas.

Wonga Pigeon (*length* 15 *in.*).

The largest member of the family is the Wonga Pigeon (*Leucosarcia melanoleuca*), an inhabitant of the scrubs of eastern Australia from Cape York to Victoria. Perhaps the best-known of all the Australian pigeons is the Bronze-wing (*Phaps chalcoptera*), found in open forest country throughout the continent, and much sought after by sportsmen; the allied Brush Bronze-wing (*P. elegans*) inhabits the coastal scrubs of eastern Australia, and extends to Tasmania. This was the first Australian land-bird to be met with by Europeans. Pelsart (q.v.), describing the fauna of the Houtman Abrolhos group in 1629, mentions that in the two largest islands (now called the Wallaby Islands) in addition to 'large numbers of a species of cats, which are very strange creatures,' (the wallabies) 'we also found a number of grey turtle-doves.' As this pigeon is still plentiful and breeds on

the islands, and no other species occurs there, it seems certain that Pelsart refers to the brush bronze-wing.

Most of the remaining members of the family are inland birds and live principally on the ground, feeding on the seeds of grapes and desert shrubs. In the evenings and early mornings they visit waterholes in great numbers to drink, and many Australian explorers have been

Bronze-wing Pigeon (*length* 13½ *in.*).

indebted to them for a hint as to where water could be found. Forms confined to the interior are the Harlequin Pigeon or Flock-pigeon (*Histriophaps histrionica*), the Crested Bronze-wing (*Ocyphaps lophotes*), two species of partridge-pigeon (*Geophaps*), two plumed pigeons (*Lophophaps*), and two rock-pigeons (*Petrophassa*).

The small pigeons generally known as doves are also members of this family. There are three indigenous species, the Peaceful Dove or Ground-dove (*Geopelia placida*), found throughout eastern and northern Australia, the Diamond-dove (*G. cuneata*), and the Barred-shouldered or Mangrove-dove (*G. humeralis*), commonest in the north. Two species of turtle-dove have been introduced, and are now thoroughly acclimatized in the neighbourhood of the large cities. The Indian Turtle-dove (*Turtur suratensis*)—commonly called the Java Dove—is one of the most familiar birds in Melbourne, Sydney, Brisbane, and Perth; the Senegal Turtle-dove (*T. senegalensis*) is common about the last-mentioned city.

Fruit-pigeons (Treronidae) are specially characteristic of the forests and jungles of southern Asia and the Malay Archipelago, but eight species occur in the coastal scrubs of northern and eastern Australia. Most are birds of brilliant plumage, vying with parrots in splendour. The best-known is the Nutmeg or Torres Straits Pigeon (*Myristicivora spilorrhoa*) which annually reaches northern Queensland in enormous numbers, breeding principally on islands off the coast and flying daily in great flocks to the mainland to feed in the scrubs. Its white plumage, relieved only by some black in the wings and tail, and its habit of flying low over the water, give it a great resemblance to a sea-bird. Another interesting Australian fruit-pigeon is the Top-knot Pigeon (*Lopholaimus antarcticus*), which derives its name from a curious double crest on the head. It occurs all along the east coast, and was first met with on the Endeavour River during Captain Cook's first voyage, when a number were shot for food.

W.B.A.

Pigfish. See WRASSES.

Pigs. The pig succeeds admirably in Australia and, with the exception of a few rare local outbreaks of preventable sickness, is remarkably healthy. He has made himself perfectly at home in the continent, running wild in many areas, such as the Macquarie marshes and the 'watercourses' in the north-west of New South Wales, the interior of northern Queensland, and the northern portion of the Northern Territory. In some places his appearance has reverted to that of his ancient progenitors, but for the most part the improved type has been preserved to a remarkable degree, especially in the Northern Territory, where food is abundant and easy to obtain. The wild pig's choicest delicacy is the root of the water-lilies which abound in the lagoons and billabongs. Although extremely wild when at large, when brought in he fattens well for market purposes.

Pigs were introduced into Australia along with the first white settlers. On 1 May 1788 there were 49 hogs and 25 pigs in the settlement, but by 1791 only 47 were left. In order to save expense in breeding stock, most of the government pigs were distributed to farmers. The production of swine's flesh in the early days was a matter of considerable importance, as fresh beef and mutton were practically unprocurable. In 1800 the swine numbered 2390; in 1817 they had increased to 17,842, and next year to 24,822. In 1826 James Atkinson, in his *State of Agriculture and Grazing in New South Wales*, discoursed much upon pigs:—'In seasons when the maize crop is abundant a great quantity of fine pork is fattened upon that grain, which is given to them whole; in the higher districts peas are much used, also potatoes, rye and barley which are given in a raw state . . . Pork fluctuates much in price but usually fetches from 6d. to 9d. per pound.' In 1821 there were nearly 34,000 pigs in the colony, 66,000 in 1842, 121,000 in 1851; but the unsteadiness of the rise since then is remarkable, not corresponding in any way to rainfall records or the other phenomena that affect live stock. Thus 1872, 1880, 1890, and 1904 were good pig years followed by falls, whereas for cattle, sheep, and horses they were moderate years followed by rises. In 1904, 1911, and 1917 Australia owned over a million pigs—in 1917 was attained the maximum number, 1,169,365. In proportion to population the number of pigs has of recent years much diminished; in 1880 there were four pigs to every 11 inhabitants, in 1923 only four to every 25.

Breeds.—For many years pig-breeding was carried on with the utmost carelessness. In 1870 the official report of the intercolonial exhibition, in its section dealing with pigs, lamented that 'Nothing very definite can be stated as to the particular breeds. A few gentlemen have

Drawn by Neville W. Cayley.

(*Lopholaimus antarcticus*).

White-headed Pigeon
(*Columba norfolciensis*).

Nutmeg Pigeon
(*Myristicivora spilorrhoa*).

kept special breeds in stock, and with regard to the produce of their own farms have maintained a pure race, or crossed them for particular reasons. But, as a rule, the farmers pay no attention whatever to the breed of pigs, nor has any systematic attempt been made to determine whether particular kinds are specially adapted to different parts of the Colony.' At that exhibition prizes were offered not for any particular breed of pig, but for large breeds, small breeds, long-bodied pig, for boar of any age, sow of any age, sow and litter, and fat pig. A breed greatly in favour then and earlier was the Old China, traces of which may still occasionally be found; the American Poland-China also came into prominence at that time. Since then, however, great care has been bestowed on improving the breeds of pig, as well as the methods of curing bacon.

The principal breeds suitable to Australian conditions are:—the *Berkshire*, which is the favourite, thrives everywhere, and is unaffected by extremes of climate; the *Large, Middle*, and *Small Yorkshire*, all quick-growing and early-maturing breeds, good bacon-pigs, producing lean meat; the *Tamworth*, specially valuable for crossing with fat breeds; the *Large Black*, a bacon-pig, giving well-streaked bacon of firm texture; the *Poland-China* (an American breed), having fat carcases and fattening quickly, and consequently of special value for pork-production. The best crosses are the Berkshire and Middle York cross—a special favourite in Queensland, where it can be fattened up for sale in seven months—and the Tamworth and Poland-China cross. Classifying the breeds according to colour, the best modern breeds are: —*Black*: Berkshire, Large Black, and Poland-China. *White*: Large and Middle Yorkshire. *Red*: Tamworth.

Statistics:—

	Number of Pigs, 1924-5.	Bacon and Ham. lb.
New South Wales	339,669	21,115,901
Victoria	288,509	21,993,869
Queensland	156,163	15,640,561
South Australia	80,988	5,374,457
Western Australia	66,375	2,797,151
Tasmania	47,305	2,428,966
Northern Territory ...	609	—
Federal Capital...	—	—
Total	979,618	69,350,905

The value of exported pig-products in 1924-5 was:—Bacon and ham, £124,891; lard and refined fats, £42,744.

W.S.C.

Piguenit, CHARLES WILLIAM (1836-1914), born at Hobart on 27 August 1836, in 1849 entered the Tasmanian survey service and in the course of his duties made several arduous journeys in the western highlands of the colony, often sketching the wild scenery through which he travelled. In 1872 he retired from the service, and began to revisit his old haunts in order to paint them. In 1874 he thus traversed the Huon and Gordon valleys, in 1876-80 the south-eastern and eastern districts; in 1876 his picture of Mount Ida above Lake St. Clair was bought by James Agnew (q.v.), and thenceforward his skill as a painter was generally recognized. In 1880 he settled in Sydney and helped to found the Art Society of New South Wales (see ART). In 1887-8 he revisited Tasmania and made pictures of Derwent valley and West Coast scenery which attracted much attention, so that the colonial government put a vote on the estimates to purchase eight of his monochrome paintings for the Hobart gallery. In 1901 he was awarded the Wynne prize at Sydney (see ART GALLERIES), and in 1903 was commissioned by the trustees of the Sydney gallery to paint Mount Kosciusko. During a visit to England in 1898 he painted several landscapes which were bought and engraved by Henry Graves and Company, then the principal engravers in London; during a second visit in 1900 he did a good deal of work in North Wales, and exhibited at the Old Salon in Paris. Probably his best work is 'The Valley of the Upper Murray,' which hangs in the Australian Club at Sydney. He died at Hunter's Hill near Sydney on 17 July 1914.

Pilbarite. See MINERALOGY.

Pilchard. The Australian pilchard (*Sardinia neopilchardus*) is scarcely distinct from the pilchard of Europe. It occurs periodically in vast shoals on the coasts of south-eastern Australia and Tasmania, and provides an abundant food-supply for large fishes which pursue the shoals as they migrate northward. Otherwise little definite information is available about their habits and migrations. They have occasionally appeared in such numbers as to be procurable by the ton by simply dipping them out of the sea with buckets. They range northwards into the waters of southern Queensland, and round the southern coast of Western Australia. No organized effort has been made to capture and market the Australian pilchard. The young of the European species (known as sardines) are tinned, and huge supplies are imported into Australia each year, but the locally-procurable sardine is entirely neglected.

Pilot-bird, a bird (*Pycnoptilus floccosus*) about six inches long, the sole member of its genus, confined to south-eastern Australia. Its classification is quite uncertain; it has usually been placed among the Timaliidae, and is probably related (as suggested by G. M. Mathews) to ground-wrens, field-wrens, and scrub-wrens.

The pilot-bird lives in secluded gullies, where it passes most of its time on the ground, hopping

Pilot-bird (*length 6½ in.*).

about among tangled vegetation in search of insects and seeds. One of its clear calls, which can be heard for a considerable distance, resembles the words 'guinea-a-week'—a name by which it is sometimes known. The name 'pilot-bird' was bestowed on it because it frequently accompanies the lyre-bird to pick up scraps unearthed by the latter, just as the pilot-fish attends on sharks.

The pilot-bird is dark chocolate-brown above, rufous on the breast, and white beneath, with a patch of chestnut below the tail. It builds a dome-shaped nest of grass and leaves, with the entrance at the side, among thick undergrowth near the ground. The two eggs are purplish-brown, with some blackish marks on the larger end.

W.B.A.

Pilot-fish, an oceanic species (*Naucrates ductor*) that roams the seas of the world throughout temperate and tropical regions. It commonly associates with sharks, and popular belief credits it with the habit of piloting them into safety when danger threatens—it is even supposed to render the same service to ships. Its association with both sharks and ships, however, is due to the supply of food-scraps available from their leavings. The pilot-fish is strikingly marked with broad, blackish cross-bars upon a whitish ground-colour; its torpedo-shaped body is admirably adapted for speed, offering but little resistance to the water, and so enabling it both to keep pace with, and to avoid the attacks of, its giant associates. It grows to a length of about two feet. See SUCKING-FISH.

A.R.McC.

Pimelea. See THYMELACEAE.

Pimpernel, English. See NOXIOUS PLANTS.

Pinchgut, a small rocky island in Port Jackson named by the aborigines Mattewaya and officially known since 1856 as Fort Denison, was when the first settlers arrived a gray, weather-beaten rock rising perpendicularly in a slender column 75 feet above the water. Phillip called it Rock Island and found it a convenient place on which to maroon refractory convicts; from their sufferings when thus exposed on a bread-and-water diet in full view of all the Port Jackson shipping the island got its more usual and colloquial name. Hunter occasionally used it for hanging a criminal 'in chains;' but the spectacle scared the natives and did not in any way terrify the other convicts, so the practice was abandoned. In 1839 Major Barney (see MILITARY DEFENCE) recommended that the island should be used as the site of a battery for harbour defence, and in 1840 cut it down almost to water-level for that purpose, but the British authorities refused to let him do more. In 1855 Sir William Denison, just made governor of New South Wales, revived the Barney defence-scheme (though it was long out of date) and constructed on Pinchgut the central fort, which he named Fort Denison; as soon, however, as his influence was removed, the inner harbour forts were abandoned and attention was concentrated on those nearer the harbour mouth. Fort Denison, therefore, with its antiquated martello tower, was never in active use, and became merely a storehouse for discarded cannon and ammunition. When the Commonwealth took over defence the stores were gradually removed and the island handed back to New South Wales. It is now maintained as a place of pseudo-historical interest, and used for harbour signals and for the display of fireworks on gala nights; proposals have been made to place on it a gigantic statue after the pattern of the statue of Liberty in New York harbour.

Pineapples. See FRUIT-GROWING.

Pines. This name is popularly given to a number of different trees belonging to the families Pinaceae and Taxaceae. *Pinus* (the true pine) is not represented in Australian indigenous flora. Of the Pinaceae the genus *Agathis* extends to Malaysia and New Zealand; two species are endemic in Queensland. *A. robusta* (Queensland Kauri) is a coastal tree 80-130 feet high, with a timber very like that of the Kauri pine of New Zealand (*A. australis*). *Araucaria* represents a form of vegetation, distinguished by simplicity of structure, now extinct in many parts of the world; it is most abundant in New Caledonia,

Araucaria Bidwilli

and extends to Papua and South America; one species inhabits Norfolk Island and two are indigenous to Australia. *A. Bidwilli* (the Bunya-bunya of Queensland) is often cultivated as an ornamental tree in the other States. The large seeds are sweet before they are ripe, but when fully matured taste like roasted chestnuts. Once in three years they are very plentiful, and the aborigines used to assemble from long distances to feast upon them. Each tribe had its own particular set of trees, of which a certain number were allotted to each family and handed down from generation to generation; the bunya, indeed, was the only hereditary property the aborigines were known to possess, and was therefore protected by law. The food is roasted and eaten in large quantities, and appears to have a fattening effect. Contrary to their usual habit, the aborigines sometimes stored the nuts, hiding them in a waterhole for a month or two. The tree has a useful timber, and exudes a pure, clear resin. *A. Cunninghami* (Hoop, Moreton Bay, or Richmond River Pine) ranges from northern New South Wales into Queensland. It

yields a valuable timber (of which the mountain-grown is preferable to the coastal) and exudes an almost colourless resin, which sometimes hangs in amber-coloured pendants 3 feet long and 6-12 inches wide, smelling like Canada balsam. *A. excelsa* (Norfolk Island Pine) is naturally limited to that island, but has been widely planted throughout southern Australia; it is especially suitable for exposed sea-coast stations. *Arthrotaxis* is limited to Tasmania, where three species (small to medium-sized trees) grow in the western mountain district. *A. cupressoides* is the original King William (or King Billy) Pine, named in honour of William IV. *Callitris*, among whose species are the black (or red) pine, the white (or common) pine, and the Middle Harbour pine, is treated separately.

Of the Taxaceae five genera are indigenous to Australia. *Dachrydium* has one indigenous species, *D. Franklini*, the famous Huon Pine of Tasmania, named in honour of Sir John Franklin. Owing to the durability of its timber (which is specially adapted for boat-building), it has been greatly in demand, and is now becoming scarce, the species being limited to Tasmania. The genus *Phyllocladus* (in which phyllodes take the place of true leaves) extends to Malaysia and New Zealand; one species only, *P. rhomboidalis* (Celery-top Pine), is endemic in Tasmania. It is a stately tree of 50-60 feet, with a timber much in request for ships' masts and spars. *Podocarpus*, extending to South America and eastern Asia, comprises 6 indigenous species, which have edible fruits known as 'damsons,' consisting of the fleshy fruit-stalk expanding into a receptacle upon which the seed is seated. *P. elata* (She-pine or Brown Pine) is a large tree, ranging from New South Wales into Queensland, with a tough interlocked timber, fine in the grain and not readily attacked by white ants. *P. spinulosa*, endemic in New South Wales, is a spreading bush with prickly-pointed leaves; the fruits, mixed with those of the native currant, are made into puddings. *P. Ladei* (Mount Sturgeon Pine) is a large tree, found in Queensland. *P. alpina* is a straggling undershrub, found at high elevations in Tasmania and on the Australian Alps. The only species found in Western Australia is *P. Drouyiana*, which in the south-west is considered an indication of poor land, and is known locally as 'emu-berry.'

Pipe-fishes. See SEA-HORSES.

Piper, JOHN (1773-1851), born at Maybole, Ayrshire, in Scotland, entered the army on 20 April 1791 as an ensign in the New South Wales Corps (lieutenant, 1795; captain, 1800; captaincy confirmed by war office, 1806). Arriving in Sydney on 14 February 1792, in the vessel that brought out Grose, he was in 1793 sent on duty to Norfolk Island, but in 1797 went home on leave and, when he returned in 1799, was kept at headquarters and allotted grants of land. When Paterson in September 1801 challenged John Macarthur (q.v.) to a duel, Piper acted as Macarthur's second, and was put under arrest by King; a subsequent court martial, however, acquitted him of any breach of discipline, and in 1804 (after two years' service at Parramatta) he was again sent to Norfolk Island, of which he was commandant from 1805 to 1810, 'with great credit to himself'—to quote Macquarie—'and the satisfaction of the Governors-in-chief of this Territory.' He also gained Macquarie's favour by his wise and just advice with reference to claims arising out of the removal of Norfolk Island settlers to Tasmania.

Leaving Sydney on 19 October 1811, he took Macquarie's despatches to England and was for about a year placed in charge of the 100th regiment, then stationed at Winchester. But he was anxious to return to Australia, and early in 1813 retired from the army and secured from Bathurst the appointment of 'naval officer'—i.e. harbour-master and collector of customs—at Sydney. There he settled down, living at first on the western side of Sydney Cove, and using Vaucluse House as a week-end cottage. He then moved to Burwood, and finally built himself a fine house on Point Piper, then known as 'Eliza,' 'Elizabeth,' or 'Elizabeth Henrietta' Point. His hobby was horse-breeding and racing, and until 1821 he was a steward of the Sydney Jockey Club. Through Macquarie's and Brisbane's terms he held his office undisturbed, efficient on the whole, and extremely popular, but (as might be expected from such a 'good fellow') inclined to laxity in the collection of moneys due to the government. Consequently, when Darling arrived in 1826, full of zeal and contempt for Brisbane's leniency, he almost at once fell foul of Piper both in his capacity of naval officer and in that of president of the bank of New South Wales. Enquiries showed that the bank had granted its friends 'great and improvident accommodation,' and that the naval office (partly because Piper's staff was quite inadequate to its multifarious duties) had failed to collect a good deal of revenue. In 1827, therefore, Piper resigned his presidency and was retired from the position of naval officer—which was abolished in favour of a regular customs establishment. To pay off arrears due to the government he was compelled to sell all his Sydney properties (including Vaucluse House) as well as his suburban and country farms. He retained, however, a large estate near Bathurst, called Alloway Bank, and settled there for the rest of his life, entertaining Darling there in 1829—a clear proof that the mistakes he had made in Sydney were not regarded as affecting his personal honour. At Bathurst he was visited by old friends high in public life, whose confidant and adviser he was; and there he died on 30 June 1851.

His popularity, especially among sea-going men, is shown by the repeated occurrence of his name on the map; it is borne by a river in Tasmania, a cape and some islands in the Northern Territory, and several localities near Sydney.

Piperaceae, a family of herbs, shrubs or climbers widely distributed in temperate, but chiefly in or near tropical, regions. Two genera are indigenous to Australia; *Piper*, one of them, has seven indigenous species. The flowers are small, in terminal spikes. *P. Novae-hollandiae* (Climbing or Native Pepper) creeps like ivy up the trunks of the tallest trees. It affords a stimulus to the mucous membrane; its active principle is a brownish oily fluid, with a pleasant aromatic taste and a benumbing effect on the tongue, even in small quantities. The wood is coarse-grained, and pungently-scented when newly cut. *P. hederaceum*, also a climber, is a good honey-yielding plant. The genus *Piperomia*, of which five species are known, consists of small, inconspicuous herbs.

'Pipes,' the name given to certain scurrilous papers which were circulated in the earlier days of the colony of New South Wales, lampooning high-placed officials or other well-known persons. The word is a slang term, and is the noun of the verb 'to pipe,' that is, to watch a man and in

some way victimize him. The first 'pipes' were circulated in 1803 against Governor King, whose efforts to prevent the sale of rum (see RUM, TRAFFIC IN) met with much hostility. The authors at first contented themselves with making 'most seditious drawings . . . in the barrack yard.' The next day an 'anonymous seditious paper made its appearance, said to have been found in the yard of Capt'n Kemp's barrack.' Two days later a 'paper of the same kind was found near an officer's barrack,' and after another three days 'another paper of a still more seditious nature was found, as said, in a chaise belonging to Lieut. Hobby, of the New South Wales Corps, who...took it to Parramatta, where he read it and published it to different persons.' A copy was obtained by Ensign Bayley from Major Johnston, 'which he also did his utmost to disseminate.' King immediately ordered the officers to be tried by court martial. As the court consisted of brother officers, the charges were dismissed, leaving the governor to complain bitterly to Lord Hobart that 'a Governor has very little chance of justice where he is so situated, having only one Corps, and but a sufficiency of officers to sit [as] a Court-Martial, and being unable to manage the prosecution in person.' The excerpts given below show the nature of the 'pipes' in question. The first was sent to Captain Abbott 'and the rest of the officers' after the recovery of the governor from a serious illness, and purports to be a conversation between eight officials; two verses put into the mouths of John Harris and Samuel Marsden are here quoted:—

H-r-s.

To every loyal Christian feeling heart
The earnest news I hastily impart;
Congratulate you all, Te Deum sing!
Escaped from death and gibbet is our K——g!

. . . . .

M-rs-n.

He now resumes his old indignant sway,
And gives this notice: That on every day,
Sundays excepted, will be exposed to vend
All public stores that Government may send,
As well as those in hand;—'twill make him rich,
And save the howling pains of dying in a ditch.

'Keep shop' in the second verse of the following refers to the fact that on Mondays Governor King used to superintend the exchange of government stores for the settlers' grain.

Extempore Allegro

My power to make great
O'er the laws and the State,
  Commander-in-Chief I'll assume;
Local rank, I persist,
Is in my own gift [fist],
  To doubt it who dare shall presume?

On Monday keep shop,
In two hours time stop,
  To relax from such kingly fatigue,
To pillage the store
And rob Government more
  Than a host of good thieves—by intrigue.

For infamous acts from my birth I'd an itch,
  My fate I foretold but too sure;
  Tho' a rope I deserved, which is justly my due,
I shall actually die in a ditch—
                And be dammed!

The lampoon circulated by Lieutenant Thomas Hobby contained the following:—

——————— Pitt and Portland are out,
Then says K—g, "I soon shall be put to the rout;
But damn me, while powerful, I'll do what I can,
According to what I proposed as a plan,
To make all subservient, humble, and poor,
Take women and children all off from the store,
Crush all independence and poverty plant,
Ruin, tense, and distress, and make every one want.
If my power was not stinted, I'd make the world shake,
Give serjeants commissions and officers break,
Which already I've tried, but in vain showed my spite,
And bit my own tongue when nought else I could bite.
I'd civilians give trust, confide in new faces,
Make magistrates of them and give them new places.
No servant of mine shall know what remorse is,
And my cook takes her pleasure on Government horses.
The convicts I'd starve, and sell all their rations,
As well as their slops, for my private occasions.
The salaries of superintendents are mine,
If e'er they neglect to secure them in time.
From the orphan collection I take what I dare,
Of whalers' investments I own I've a share.
Tythes, taxes, and quit-rents unto me belong,
And duties on spirits I claim as my own.
Such pickings are surely beyond all resistance,
And such as I covet for future subsistence."

It ended with the words:—

Blush! grandeur, blush! Proud courts, withdraw your blaze!
Ye little stars, hide your diminished rays.

In September 1817 Lieutenant-colonel Molle libelled D'Arcy Wentworth in a letter to Macquarie complaining that Wentworth had 'grossly insulted and threatened' him. Wentworth was in consequence placed under close arrest on 9 September. Soon after, there was found in the barrack-yard a scurrilous lampoon which was attributed to him, but was afterwards admitted to be from the pen of his son. No copy of the lampoon is to be found, but the following dialogue between Cacomanus (Alexander Riley) and Janufacies (Molle) gives a fair notion of the original 'pipe.'

Cacomanus Loquitur

Dear Janu, I hear that the rascally Pipe,
Which, alas, gave YOUR Honour so dreadful a wipe,
Has created such Laughter all over the town
That a Death Blow is given to all your renown,
And instead of believing that wonderful Story
You tell us so often o'erwhelmed you with Glory,
The people—such rascals, Oh may they be damned!—
Refuse any longer by us to be crammed,
And believe that your *Laurels* all turn out at last
To be stolen from the Brow of the brave *Pendregrast.*
And many of those whose favor we've Courted
Swear that Justice must sleep, since you're not here transported.
And the wretches so prone are to ridicule after
That your Medal from Egypt excites them to Laughter,
And they say, when you talk of the Pyramid *Pile,*
That the fact is well Known, you ne'er crossed the *Nile*;
And I know not, indeed, how this point you'll recover.
But they swear, you came when the fighting was over,
And that, e'en if you swore it until you were tired,
You never in Action saw a *Shot fired,*
And, more, that your Medal should from you be torn,
As you know it is ordered they no more are worn.
For that Wellington's Heroes alone have obtained
Distinctions that *Valor* and Bloodshed have gained,
While those gained like yours, 'stead of hon'ring the bearer,
Reflect everlasting disgrace on the Wearer.
Say, what shall we do, how recover your fame?
Or shall we despise it? 'tis but a name—

Janufacies Respondet

Oh! this terrible Pipe! What a downfall is here,
That all is detected, alas, is quite *clear.*
Farewell to all boastings of Storm and of *Breach*;
The *Drill* and the Review are now all I can reach,
And in future, Dear Caco, I fear 'tis my Doom
To confine all my stormings to *Subs'* barrack-room,

Where with power supreme, I can storm without *measure*
And writing Desk Locks can break open at pleasure.
How cruel my fate! All my searches in Vain;
The wicked *Pipe Maker* despises my Pain,
While, secure in his Covert, he laughs at my trouble,
At the loss of my fame, which you think but a *bubble*.
But, Dear Cacomanus, how dreadful the thrust
The Vile Pipe Maker gave when the Bubble he burst
And all my Vain glories. Seringapatam
All gone to the *Devil*, not valued *one damn*.

The rest of the dialogue is in the same vein. Macquarie is referred to as 'Sandy,' D'Arcy Wentworth as 'Medicus,' Molle is 'Janufacies' (i.e. Double-faced).

Wentworth also lampooned his father without compunction, as the following pipes show:—

On hearing that a ci-devant Quack Doctor was actively employed in circulating the Bank Bills of a Certain Magistrate, who had formerly rendered the Doctor the same Service in distributing his Hand Bills:—

Par nobile Fratrum
"Hail, gratitude! blest attribute of Heaven."
Milton

In days of Yore, the Count was used to stop
Each passing stranger, and of Daffy's shop
Into his hand would slip a puffing Bill,
Swearing besides the virtue of the Pill.
So Daffy's turn 'tis now, to set afloat
His old acquaintance's new One pound Note.
Peter Paste Pot.

Impromptu

On seeing a person officiating as a Magistrate, who was recognised by the Author as having formerly been engaged, in his Capacity of Bill Sticker, in placarding the puffing Bills of the celebrated Dr. Leake.

Non sic olim
Remember thee, alas, poor Ghost! *Hamlet*

Divinity, Law, and Physic—as they say—
Stand in Mutual relation of Brother.
It is thus that the Count then distributes one day
His Physic, his Law on Another. Quiz.

Hint to a certain Magistrate, who terribly threatened the Pipe Maker:—

Tantacne animis caelestibus irae?
Dread Sir: how cruel in such Doggerel Rymes,
T' expose to Vulgar Eye the good old times,
When you, Industrious Man, by Labour hard
And Paste, and Hand Bill, gained but poor reward.
Take my advice, the *piper* to Appal,
Whene'er you meet him, stick him against the *wall*.
Dick Dab.

On hearing that a certain Magistrate devoured a prodigious Quantity of Plum pudding, at a late dinner at Government House:—

Propositi tenax
A certain great Count, at a dinner of late
Ate of pudding, they say, at least a pound weight.
No wonder; for can we forget it in haste,
How much of his Life he had Dabbled in Paste?
Ben Brush

Another curious pipe, which was plastered on posts of the town, reads:—

Doctor Halloran is a coward, he having by letter insulted and challenged a young man to meet him which was excepted (*sic*) but the Doctor's boasted courage failed him

July 30 1824
For further particulars Enquire Wics clap match and pup Fir Seal skins

A carelessly printed brochure entitled *To Bourke's Statue* was circulated in the fifties. It declared itself to be 'an appropriate effusion . . . . unceremoniously dedicated by Ichneumon, anxious to instruct his Grandmothers in the inductive science of sucking eggs,' comprised 31 pages, and lampooned most of the leaders of the day. It was found out afterwards that it was the work of T. L. Mitchell, jun.

Sir T. L. Mitchell (the poet's father), finding a copy of the pamphlet on his desk, read it with great gusto until he came upon:—

See him of aspect dire and haughty gait,
As though himself were a triumvirate,
Who dreams of honors, forges Bomerang screws
And wakes in anger Camoen's lofty muse;
Who damns the language that cooked such rhyme
(To spoil the Lusiad were a heinous crime:)
Your childish choler but provokes a sneer,
And makes you small, the very smallest beer.
With Sisyphic attempts Fame's temple try,
No niche is there for eccentricity—
High *roads Colossus*, once was yours the power
To move each bullock team as coach and four.
Why did you fail, when yours the ironed man
To make the 'high hills hop' as hop'd 'Bashan?'
Go grave your maps, in survey you succeed;
Where praise is worthy, let me grant the meed,
Thousands of men and money shout for land,
But here as elsewhere work is at a stand.—

It will be seen from these specimens that 'pipes' had but small claim to literary merit. The verses are mostly doggerel, although it is probable that their authors sometimes thought otherwise. Latin was almost an essential of the education of the time, and the writers are fond of airing their little schoolboy tags of that language. It was also the day of punning, and care was taken that a pun should not be overlooked for want of underlining or italics. If, for instance, we meet with '*Highroads Colossus*,' we are to think of the Colossus of Rhodes. The spelling is not always of the best, and a challenge may be 'excepted;' the punctuation, whether of the manuscript copies (now in the Mitchell Library at Sydney) or of such sheets as got into print, is generally hopeless, and it is tolerably clear that the hands which copied the 'pipes' were not those which first wrote them —a sufficiently comprehensible precaution.

J. V. C.-B.

Piping Crow. See MAGPIES.

Pipits. See LARKS AND PIPITS.

Pipturus, a small genus of the family Urticaceae, dispersed over Malaysia. *P. argenteus* (Native Mulberry or Queensland Grass-cloth Plant), is a tree which may reach a height of 50 feet. It is the 'coomeroo-coomeroo' of the aborigines, who use the white berries as a food. The inner bark affords a fibre of fine texture and great strength, but is rather difficult to prepare. It grows in the brush forests of New South Wales and Queensland.

Pitcairn Island. See BOUNTY, MUTINY OF THE.

Pitcher-plant, a name popularly applied to species of *Nepenthes*, a large genus of the family Nepenthaceae, widely spread over tropical Asia and Malaysia, and especially abundant in northern Borneo. The few species endemic in Australia are practically confined to the Cape York Peninsula; they are shrubs or undershrubs with herb-like branches full of spiral vessels. The stems are diffuse, or climbing by means of tendrils on the ends of the leaves; base of the leaf-stalk winged and stem-clasping; the midrib produced either into a tendril or a pendulous pitcher provided with a lid, the margin of whose orifice is thickened and usually has an external spur; flowers small, green, in clusters.

The Western Australian Pitcher-plant is *Cephalotus follicularis*, belonging to the family Saxifragaceae; it bears ordinary as well as

pitcher-shaped leaves, the latter being formed by a pouching from the upper surface of the ordinary leaves. Glands on the interior of the

Western Australian Pitcher-plant.

pouch secrete—as do those of the *Nepenthes* species—a sweet fluid with digestive properties.

Pittas, small and brilliantly coloured terrestrial birds, with short tails and long legs, belonging to the family Pittidae. They are most abundant in the Malay Archipelago, but extend north to China and west to West Africa. 'Pitta' is the Telugu name for one of the species. Three species occur in Australia; two are confined to

Noisy Pitta (*length* 8½ *in.*).

the north of the continent, the third, the Noisy Pitta or Dragoon-bird (*Pitta versicolor*), extends south along the east coast to northern New South Wales. This species has a black head, deep-green back, black tail and wing-quills, and buff-coloured breast; there are patches of brilliant metallic blue on the shoulders, of bright scarlet under the tail, and of white on the wings. It frequents the densest parts of the scrubs, feeding on insects, snails and fruits, and would rarely be seen if it did not draw attention to itself by a loud call (resembling the words 'walk to work') which it constantly repeats.

W.B.A.

Pittosporaceae, a family of trees, shrubs, or climbing plants. Eight genera, containing 50 species, are indigenous to Australia. The flowers are of various colours; fruit a capsule. *Hymenosporum,* with one species (*H. flavum*) extending from northern New South Wales into Queensland, is a highly ornamental slender tree with showy yellow flowers, often to be seen in gardens. *Bursaria spinosa* (Blackthorn) is a spiny shrub (or small tree) with sprays of small white flowers, extending throughout the Commonwealth. It has a white wood. Sheep are fond of the leaves, but, owing to the strong thorns, can only nibble the ends of the branches. It is unfortunately very liable to attack by a waxy scale (*Coccus*), and hence is one of the very few native plants proclaimed a pest at the instigation of fruit-growers. *Marianthus* has 14 species, chiefly found in the western areas, mostly prostrate or twining undershrubs with blue, white, or reddish flowers. *Citriobatus* has two species confined to eastern Australia—rigid, much-branched shrubs armed with thorns. *C. pauciflorus* (Orange-thorn) has an edible, orange-coloured berry well known to the aborigines; it has been suggested as a hedge-plant, but, like so many of the Pittosporaceae, is a prey of insect-pests. *Billardiera* is a largely western endemic genus of 8 species, mostly climbers with showy flowers; *B. scandens* (which ranges from South Australia to Queensland) has an elongated fruit called by children 'dumplings,' acid and not unpleasant when ripe. *Sollya,* with 2 species, is exclusively western. *S. heterophylla,* a commonly cultivated twiner, has nodding clusters of bright blue flowers. *Cheiranthera* is endemic, largely western. *C. linearis,* a low twiggy shrub often seen in gardens, has pretty blue flowers and extends from Western Australia to Queensland. See PITTOSPORUM.

Pittosporum, a large genus of the family Pittosporaceae, consisting of trees or shrubs dispersed over the warmer regions of Africa, Asia, Malaysia, and New Zealand; the species indigenous to Australia are mostly endemic. The leaves are usually entire; flowers more or less tubular; seeds embedded in a viscous or resinous substance. *P. undulatum,* indigenous to eastern Australia, is largely grown as an ornamental tree, whose unisexual flowers (the sexes borne on different trees) are heralds of spring in New South Wales. It has been suggested that the oil obtained from these might make a suitable basis for a perfume, the tree yielding a gum resin with a powerful odour of turpentine. The bark contains medicinal properties, and yields a fair percentage of both tannic and gallic acids; the timber is sought after by wood-turners. The tree, when introduced into the Azores as a wind-break for the orange-groves, was found to withstand the strongest gales. *P. phillyraeoides,* the Narrow-leaved *Pittosporum* or Butter-bush, is a small, graceful tree with willowy leaves, pendulous branches, and yellow flowers. The compressed capsules open out flat in two valves, exposing a bright yellow interior, to which the ruby-coloured seeds adhere by the aid of a gummy resin. The tree, which has a light, hard wood,

flourishes inland across the breadth of the continent, but is in some danger of extermination by grazing stock (see FODDER-PLANTS). The bitter seeds are used as food by the aborigines.

P. phillyraeoides.

P. bicolor (White-wood of Tasmania) was used by the aborigines for making clubs, and is now used for axe-handles, billiard-cues, etc.

Pituri. See ABORIGINES and DUBOISIA.

Plagianthus, a genus of the family Malvaceae, consisting of shrubs with undivided leaves and clusters of small white flowers; its ten species are confined to Australia and New Zealand. *P. sidoides* (exclusively Tasmanian, and known as the Tasmanian Kurrajong) is a quick-growing shrub that produces strong fibre. *P. pulchellus* (Hemp-bush), found in Victoria, Tasmania and New South Wales, yields a soft glossy fibre which would make good yarn.

Plain Currant. See TILIACEAE.

Plain-wanderer, a terrestrial bird (*Pedionomus torquatus*) about six inches in length, peculiar to south-eastern Australia; one of the most anomalous of Australian birds. Superficially it shows considerable resemblance to some of the small African bustards; its eggs, which are four in number and pear-shaped, closely resemble those of certain waders; but study of its internal anatomy by Dr. H. Gadow confirms the view, already adopted by Gould, that it is most nearly related to the button-quails, and it is now given family rank as the sole member of the Pedionomidae, and placed in the order Turniciformes.

The plain-wanderer is an inhabitant of open country and is solitary in habits, associating in pairs in the breeding-season, but not forming flocks like its relatives the quail. When disturbed, it usually runs rapidly like a rail, and is not easily flushed. Its flight is comparatively weak. Its coloration is mottled brown, with a black, white-spotted collar round the neck and a chest-

Plain-wanderer (*length 6 in.*).

nut patch on the breast. It stands upright, so as to peer over the top of the herbage. Its food consists of insects and seeds. Unfortunately, like most Australian terrestrial birds, it is rapidly becoming a rarity, being unable to stand the combined attacks of the man with a gun and the introduced fox and cat. W.B.A.

Planarians. See FLAT-WORMS and LAND PLANARIANS.

Planipennia, an order of insects including lacewings and ant-lions. It is well represented in Australia, about 250 species having so far been described. It is characterized by the wing-venation of the imago, in which the veins are typically split up into small branchlets along the wing-margin, and the dominance of the radial sector is generally very pronounced, a large number of parallel branches of this sector being present and occupying a large central area of the wing. The mandibles and maxillae of the larva fit together, and act as a pair of sucking-tubes. The pupa is always enclosed in a cocoon—which is unique in being spun from the larva's anus, instead of from its mouth, as in other cases.

More families are represented in Australia than in any other region of the world. Of special interest are the archaic Ithonidae, heavy-bodied moth-like insects, whose larvae burrow in sandy soil, and much resemble those of the scarabaeid beetles on which they prey. Another family not found outside Australia is the Nymphidae, which are closely related to the ancestors of the Myrmeleontidae. The well-known *Nymphes myrmeleonides* is still not uncommon at times; it is a very graceful orange-brown insect, with a strong musk-like odour.

The lovely silky lacewings (Psychopsidae) have their headquarters in Australia, 12 species being known there. One of the most beautiful is *Psychopsis elegans,* shown on plate xix, fig. 24. The larva is an extraordinary creature with big jaws, which hides in the crevices of the bark

of forest trees. The finest species in this family is *Megapsychops illidgei.*

The Sisyridae (spongilla-flies) are a very archaic family of small lacewings, whose larvae feed upon freshwater sponges. Four species are known in Australia. The Coniopterygidae are minute lacewings with snow-white wings, superficially resembling the Aleurodidae among the Homoptera. Australia has more than a dozen species; *Parasemidalis farinosa* is very abundant in some places.

The dainty little Hemerobiidae are well represented, especially by the hook-tip lacewings of the genera *Drepanacra* and *Drepanomina,* whose larvae feed upon lerp-insects on wattle and eucalyptus trees. The Chrysopidae (golden-eyes) are very abundant, though few have been described. These are among the most beneficial of all insects, their larvae destroying scale-insects and aphides wholesale. The rare insects of the sub-family Apochrysinae are also represented by a single species, *Oligochrysa gracilis.*

The remarkable Mantispidae, which have a close superficial resemblance to mantids, are not uncommon. Their larvae feed upon spiders' eggs. The largest species is *Mantispa australasiae,* which expands to more than two inches. *Calomantispa spectabilis,* from eastern Australia (shown on plate xix, fig. 26) is a little gem.

The slender and delicate lacewings of the family Osmylidae are not uncommon in Australia. *Porismus strigatus,* shown on plate xix, fig. 25, is a very pretty yellow-and-black species, often found in numbers on the trunks of trees. Its larva is long and slender, with very long jaws, and lives under the bark of trees. Most species are prettily-marked brown lacewings of the genera *Stenosmylus* and *Oedosmylus.*

Australia, especially in its dry central areas, has a large number of species of the true ant-lions (Myrmeleontidae), q.v. The allied Ascalaphidae are day-flying insects, with knobbed antennae resembling those of butterflies. Probably the most interesting and archaic genus in the world is *Stilbopteryx,* of which three species are known; their antennae are short, and they fly about swiftly in the dusk of evening, like large dragonflies. *S. napoleo,* from Western Australia, is shown on plate xix, fig. 28. The larva is a formidable-looking, black, spiny creature with an enormous head and jaws. Our commonest ascalaphids belong to the genera *Suhpalacsa* (a would-be humorous reversion of the European generic name *Ascalaphus*) and *Acmonotus.*

The delicate Nemopteridae, with their thread-like hind-wings, are confined to Western Australia and northern Queensland. The finest species is *Chasmopteryx hutti* (Spoon-winged Lacewing), a rare insect found occasionally near Perth.

See papers by Esben, Petersen, Froggatt, and Tillyard in the *Proceedings* of the Linnean Society of New South Wales. R.J.T.

Plant-breeding. Among the methods by which new varieties of plants are created, either naturally or artificially, is hybridization —taking pollen from the anthers of a flower of one species and placing it on the stigma of the flower of another distantly related. Thus the pollen of the Dog Daisy (*Chrysanthemum maximum*) of Europe, placed on the stigma of the Japanese Ox-eye Daisy (*C. Nipponicum*) produced seed from which was raised the well-known shasta daisy. The dog daisy was the male parent, the ox-eye daisy the female.

Plant-breeders also use the term for cross-breeding between two flowers of the same species (e.g. Farrer with his wheats), and for the raising of new plants by self-fertilization, followed by careful selection, or by cross-fertilization between two varieties or hybrids. Moreover, this transference of pollen may occur naturally, by the action of wind or insects. Among natural Australian hybrids the most noteworthy is probably the cross between the Kurrajong (*Brachychiton populneum*) and the Illawarra Flame-tree (*B. acerifolium*) which was given by von Mueller the name *B. populneo-acerifolium* and is commonly known as the Red-flowering Kurrajong. Among natural *Eucalyptus* hybrids is the cross between the Gray Ironbark (*E. paniculata*) and the Gray Box (*E. hemiphloia*) which has been given the specific name of *hybrida.* Several other eucalypt hybrids are recorded by J. H. Maiden.

In artificial hybridization the work of W. J. Farrer (q.v.) on wheats stands alone for its great economic value. In fruit-culture there has been no outstanding work, but excellent results have been achieved partly from chance seedlings and partly through careful selection —notably the 'Granny Smith' apple and 'Packham's Triumph' pear in New South Wales, and the 'Winter Cole' pear in Victoria. In floriculture several Australian hybridists have raised new plants of great value. Thomas W. Pockett has bred decorative Japanese *chrysanthemums* at Healesville in Victoria. At Bulla in the same State a new strain of *roses* has been raised by Alister Clark; he began with the pollen of *Rosa gigantea,* which has given to many new roses its charming foliage, vigorous habit of growth, and immunity from disease. Chief among these creations are 'Jessie Clark' and 'Black Boy' (climbers), 'Kitty Kininmouth' (pillar), 'Sunny South' and 'Lorraine Lee' (bushes), and 'Borderer' and 'Fancy Free' (dwarfs). In *daffodils* Leonard Buckland of Camperdown in Victoria has specialized in a red-cupped *Narcissus incomparabilis,* D. V. West of Casterton in trumpets of the 'Prince Alfred' type, and Alister Clark in the *Leedsi* varieties. H. B. B. Bradley of Sydney raised a new strain of *Hippeastrum,* breeding and culling them rigidly over a period of 35 years; he also, by crossing *Crinum Macowni* with *C. magnificum,* produced the finest hybrids of this genus yet raised. At his death all the plants and seedlings he had raised were presented by his widow to the State, and are now in the Sydney botanic gardens.

Among other Australian hybrids of note are *Hibiscus* George Harwood (*liliflorus* x General Courtegis), raised by G. Harwood; *Hibiscus* Rosy Morn (*liliflorus* x Conqueror), by William Selkirk; *Watsonia* Lady Fawkes (*rosea* x *coccinea*), by C. Weston; *Anthurium* T. Godwin (*andreanum* x *ornatum*), by A. D'Arcy; *Anthurium* Sir Hugh Dixson (King of Holland x *ornatum*), by T. Godwin. E.N.W.

Platypus, or Duckbilled Platypus, vernacular name of *Ornithorhynchus anatinus* (once known as *O. paradoxus*), one of the three known representatives of the mammalian sub-class Monotremata, the most primitive of mammals (see plate xxxviii). It has a short, thick trunk and short, powerful limbs. A full-grown male is about two feet long, a female 19 inches; of this length

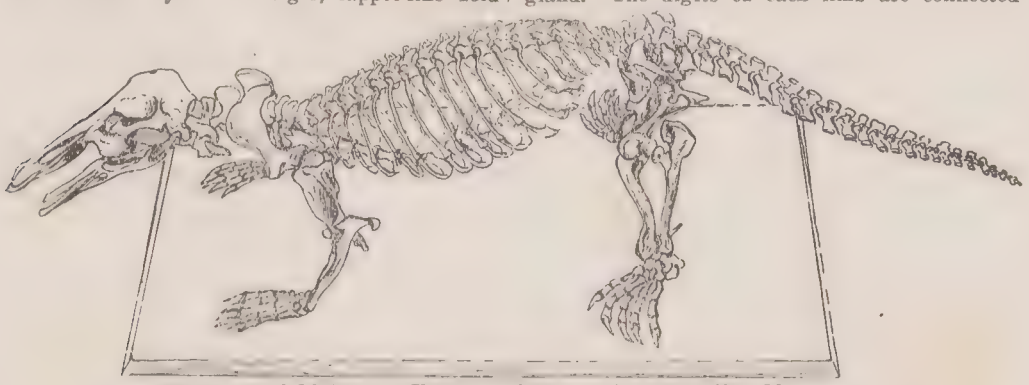
PLATYPUS BURROW

From model by H. Burrell.

Bird's-eye view of river-bank, showing platypus burrow winding 40 feet from entrance to nesting-cavity. (Scale about ¼ inch to 1 foot.)

the tail accounts for about six inches (male) or five (female). The whole surface, except the bill and feet, is covered with a coat of velvety fur, a rich brown above and grayish-white below. The snout and upper jaw are developed into a structure roughly resembling the bill of a duck, and are covered with a smooth hairless integument, black above and flesh-coloured or cream below, often mottled with dark-slate markings, and develops into a free flap at the base in front of the eyes. A larger, lappet-like fold covers the lower portion of the face, so that the animal's face is protected by the two flaps. Small, bead-like eyes and the absence of conspicuous outer ears enhance the duck-like appearance of the head. The mouth is a wide aperture, the tongue not protrusible. Both pairs of limbs are short, with five digits on each limb, all terminating in horny claws. On the inner side of the hind-limbs occur large curved and pointed horny spurs, connected with an internal gland. The digits of each limb are connected



Skeleton of Platypus. From specimen in the Australian Museum.

by a leathery flap, which in the fore-limbs extends beyond the ends of the claws; but the extension is flexible, so that it can be readily folded inwards when the animal is burrowing. These flaps convert the limbs of the platypus into very efficient swimming-organs; at the same time the strong claws adapt them for use in excavating the burrows in which the animal takes refuge. The tail is somewhat flattened, and, except in old animals, thickly covered with fur towards the end.

The burrows of the platypus—first explored by Dr. George Bennett, who described them in his *Gatherings of a Naturalist in Australasia*, and more recently by Harry Burrell, who describes them below—are excavated in the banks of streams. They are of two kinds, living-burrows and breeding-burrows. See MONOTREMES.

W.A.H.

Investigators and observers have described the platypus as 'swimming' about the surface of a pool with its sensitive beak below the surface of the water. Their observations must have been made in daylight, when these nocturnal animals are most cautious and almost sightless. At that time the platypus deliberately semi-submerges itself, so as not to expose above water any more of its body than is absolutely necessary for comfort while grinding its food, listening, and breathing. It is merely floating, turning, and loitering, while it leisurely masticates the assorted foods previously collected and stowed away in the true cheek-pouches by the aid of twin horny projections of the tongue.

Progress along a river or pool is made principally while the animal is puddling in the muddy bottom, fossicking for food; and swimming is indulged in only when it is sounding, or ascending for an occasional breath of air while it drifts. The time spent below is regulated by the quantity of food discovered during the submergences, which range from one to five minutes (averaging two). Six minutes' entire submersion means death, even to a robust platypus.

As far as is known, the animal, while puddling, relies entirely on the sensitive touch of its lips (the projecting sensitive skin that surrounds the bill) to secure its prey. The small eye-and-ear orifice is tightly enclosed in a lengthy slit which acts as eyelid and ear-lid in one, preventing the entrance of sediment. The nostrils, situated dorsally and close to the midline of the fore part of the nuzzling muzzle, are kept free from silt and sediment by an occasional exhalation of air which has been stored in the animal's lungs. Out of the five senses serviceable above water, four are completely dispensed with (or short-circuited) below, and energy is concentrated on the delicate sense of touch. The platypus does not de-pouch its assorted tit-bits for mastication until it ascends to the surface; there it systematically separates and devours the palatable food, and rejects at leisure the haphazardly collected foreign matter. When above water, the sense of hearing at least is remarkably acute. The platypus is semi-nocturnal in habit, and does not venture out during the day, except in lean seasons, when food is scarce. At such times the writer has repeatedly tested the eyesight of floating platypus, and has proved that they can see slightly at midday, especially at close quarters and when their attention has been first attracted by some unusual sound.

The platypus does swim along the surface, but not in the manner recorded by previous observers. Only during the breeding-season—or in the stillness of night, when the animal's sight is normal—does it disport itself obviously, with impunity, and regardless of all diurnal enemies. When not in quest of food, it swims rather rapidly on the surface, somewhat like a wary duck making for its nest. Action, attitude, and pace are duck-like. A portion of the back, and the bristly hairs of the tail, are exposed above the surface; the neck is comparatively sleek and erect, and the head is carried parallel with the stream. The stroke action of the fore-limbs is dog-paddle-like—by one limb at a time; and possibly alternate movements of the hind-legs occur at the same time. Action is continuous and noiseless. A shocked or infuriated platypus can, practically speaking, run

along the surface of the water, and resembles a heavy sea-bird, when suddenly surprised, scurrying along calm waters.

A platypus can bite with its ridged mandible, and will do so if exasperated, whether in captivity or at large; what is more, it will deliberately charge and savagely snap at its tormentor, snarling or hissing the while. Nesting material is cut up with the mandibles, and stiff stems and bark fractured and fuzzed to desire, to furnish and fit the rounded nesting-cavity.

The female platypus alone is responsible for all parental duties, such as excavating the breeding-burrow, tending the young, and (possibly) making the snug bird-like nest. The male, like most mammals, is simply a 'hanger-on;' he is certainly so during the rutting-season, which usually includes the months of July, August, and September. The movable spur of a male platypus is so placed that it can be used as a thumb wherewith to embrace the ankles of the female; this is, indeed, its chief use—except for combat with pugnacious rivals. All young, when hatched, are fitted with spurs; but in immature females they disappear, and the sac-like sockets that take their place are either the sockets in which they worked or the spurs themselves, altered by introversion so as to receive the tip of the male spur during copulation.

The kidney-shaped poison-glands connected with the spurs are concealed beneath muscles that lie at the dorsal aspect of the lumbar region; a duct runs from each along the hind-leg to the hollow spur. The orifice of the duct is situated slightly to one side of the spur-point, and under natural conditions the poison is ejected in measured doses. The platypus does not strike; he grips, taking hold with his curved claws and pressing the under-surface of the foot closely against his adversary, while with a powerful twist of the ankle he drives his spur probe-fashion into the part grasped, and ejects the poison. The whole action ludicrously resembles a hearty hand-shake—a friendly grip, followed by a squeeze of the hand with the in-turned thumb thrust against the palm.

Burrows.—The ordinary burrow is a simple affair, always with an entrance above the water-level, but occasionally with another under water. It is made (usually beneath the roots of a red gum) in the bank of some long, deep pool where food is likely to be plentiful. But the breeding-burrow is a very different matter. A quiet part of the stream is selected—preferably a shady pool with steep, sloping banks strengthened by the roots of eucalypts or river-oaks, and margined with reeds. When first put into the face of a bank, the entrance to a breeding-burrow varies in height from six inches to 15 feet above the then water-level. The selected site is conspicuous, and not camouflaged by herbage, although herbage may be growing abundantly close to the bare patch in which the animal has begun to tunnel. The shape of the entrance (and of the tunnel as a whole) corresponds with the cross-section of the animal's body, rounded above and flattened below. The tunnel ranges from 14 to 60 feet in length, winding erratically to left or right as obstacles and earth conditions compel; it averages 15 inches below the surface, following the sloping contour of the bank, and terminates as soon as a subsoil is met with in which the rounded nesting-cavity can be formed without fear of collapse. Provision for ventilation in a breeding-burrow, if not a lost art, is certainly overlooked.

The burrow illustrated on plate xxxix trends to the left until the roots of a she-oak are met with, then veers to the right until she sounds a somewhat similar obstacle (root of gum-tree), thence on a clear run until striking inferior soil (at mattock handle) where it terminates in a blind end. Here the animal backs out clear of the first rock soundings, then forges ahead in an opposite direction between rocks, and on again up the bank, where the burrow comes to another blind end on the platypus sounding a rabbit burrow. Backing out from this unforeseen obstacle, she digs her way between more rocks, and heads once more for the summit of the bank, only to sound the rabbit burrow again; but this time the haphazard rodent's burrow is found sufficiently elevated to induce her to tunnel under it, still keeping 12 inches of soil above her workings and rising ultimately at the other side (close to shovel) to her customary level. Here she puts in her last winding lead, carefully avoiding the roots of a felled tree on the right (near the top corner of the collector's excavation) and makes her nesting cavity 12 inches beneath the virgin surface of the steep slope. The three small cavities in the burrow not already mentioned are 'pug-pits,' from which the soil is taken for the purpose of forming the pugs when the burrow is in use. In the plate the soil is removed to expose the system of tunnelling, the area being about 12 feet x 24 and the depth 1 foot.

A platypus, when burrowing, folds its swimming membrane back into the palm of its splayed fore-paws, leaving the broad cutting-claws free to excavate the earth. After it has burrowed a short distance inwards, it tamps the loose earth back into the section of tunnel already excavated. Not until the nesting-cavity is at least partly excavated can the animal turn round comfortably in its quarters; then it immediately traverses its subway to clear away all freshly scattered soil from the main entrance. It next brings in nesting material—any suitable litter of growth obtainable close at hand, such as the fibrous roots of willows and reeds, willow-switches, strips of soft bark, reed-stems and flags, couch-grass trailers, and eucalypt twigs. Most nests are composed principally of eucalypt leaves and couch-grass trailers. When the nest is completed, the platypus proceeds to pug the subway sections, two to four in number. Entering the tunnel from outside, she scratches fine earth from the side-wall at the first bend, and with it pugs up section number 1 by backing and flicking with her tail. At the next convenient turn she creates a similar pit and pug-up, and so on until she reaches the terminal chamber; the final pug is securely arranged within a few inches of the now practically air-tight cavity. Then she wriggles herself comfortably into the centre of the snug bulky nest, coils up into a ball, and deposits her egg or eggs between her webbed palms on the slightly concave smooth surface of her tail—which, when clasped to the body, provides a temporary pouch. Forthwith she goes to sleep—probably not to awake until the eggs have been hatched and the young are about a week old, by which time her capacious milk-glands have developed sufficiently to nourish her progeny through the perforated skin on either side of her abdomen.

When the young ones have grown sufficiently robust to suck, the mother frequently leaves them securely pugged up in the chamber while she goes feeding. When they are beginning to

grow fur, and up to the time when they deliberately forsake the burrow for more convenient quarters, she does not enter the nest at all—at least during the day. But from the time when the nest is complete until the young are able to see and almost to fend for themselves, she always, when leaving or entering the burrow, pugs up the subway securely behind her, first tunnelling through and then backing to trowel (or flick) the disturbed pug again into position.

The female platypus lays from one to three eggs, two being the normal clutch. Twin eggs are always found adhering to each other, side by side. In the case of triplets, each egg may adhere to both its neighbours, forming a complete cluster; but this is not invariable. The average length of egg is 16 mm. (about two-thirds of an inch), breadth 12 mm. (nearly ½-inch), length of newly hatched young, 18 mm. (seven-tenths of an inch).

See Burrell's *Life History of the Platypus* (Sydney, 1926). H.B.

Playford, THOMAS (1837-1915), born in London on 26 November 1837, was brought by his parents to Adelaide when only six years old. His father (also a Thomas Playford, born in 1795) served in the army when young, and was present at Waterloo, but in later life became a Methodist minister and for 30 years officiated at a church in Adelaide. The son was educated at Mitcham, and for some years was a farmer and gardener at Mitcham and Norton's Summit. In 1868 he was returned to the legislative assembly from Onkaparinga as a land reformer, and helped H. B. Strangways (q.v.) to carry his land act of 1869; in 1871-5 he was out of parliament, but in the latter year was elected for East Torrens, transferred himself in 1887 to Newcastle (South Australia), and in 1890 returned to East Torrens and sat for that constituency till 1894. During those years he frequently held office—as commissioner of crown lands in the Boucaut ministries of 1875-6 and 1877-8, the Morgan ministry of 1878-81, and the Colton ministry of 1884-5 (in which he was for a time commissioner of public works), as premier (with C. C. Kingston as his right-hand man) in 1887-9 and 1890-2, and as treasurer in the Kingston ministry of 1893-9. During his 1887-9 premiership he carried the first South Australian protective tariff. He resigned the treasurership in 1894 to become agent-general for the colony, and held that position for four years. Meanwhile he had actively interested himself in the federal movement, had represented his colony on the federal council in 1889, at the Melbourne conference of 1890 (as leader of the opposition), and in the convention of 1891, and on his way to England in 1894 had attended the colonial conference at Ottawa. In the conference of 1890 he was a leading figure, heartily supporting federation within the Empire, but correcting, by a full exposition of the practical difficulties, the exuberant eloquence of other delegates; the value of his work there and at the convention of 1891 is well explained in Wise's *Making of the Australian Commonwealth.* Returning to South Australia in 1898, he was in 1901 elected to the federal senate and was vice-president of the council in the Deakin ministry of 1903-4, and minister for defence in that of 1905-8, but was defeated at the elections of 1906 and resigned his office and left politics in January 1907. He died at Adelaide on 19 April 1915.

Plectoptera, a very ancient order of insects, usually known as may-flies or ephemerae, which has no near relatives existing and no affinities to any other order except the Odonata. It is represented by about 500 species of delicate gauze-winged creatures whose vernacular name implies their brief existence in the adult stage. Australia has no conspicuous species, and only 16 in all have so far been described, though it would be possible without much trouble to obtain a good many more.

Of the seven families into which the order is divided only three—the Leptophlebiidae, Siphlonuridae, and Baëtidae—are known in Australia; the last-mentioned family is represented only by three minute species introduced from Malaysia. The Siphlonuridae are abundant and of large size in New Zealand, and similar forms may be looked for in all elevated regions of south-eastern Australia; fine larvae, indeed, have already been found on the Blue Mountains of New South Wales and in Tasmania, but have not yet been bred out. Only two species have as yet been described—*Coloburiscus haleuticus* from Victoria, and *Tasmanophlebia lacustris* from Tasmania (shown on plate xix, fig. 14). All the other species described belong to the Leptophlebiidae, the genus *Thraulus* claiming one, *Euphyurus* two, and the dominant genus *Atalophlebia* eight—but this is only a fraction of the actual number belonging to this genus in Australia. The larvae are conspicuous objects in all running creeks, very active, and often found clinging to the under-side of rocks where the current is fast. They may be distinguished at once by their three very long, slender caudal filaments, and by the six or seven pairs of tracheal gills arranged segmentally along the sides of the abdomen. Each gill consists of a pair of leaflets, usually lanceolate in form; but in some species one of them may be deeply multifid. The larvae have strong mandibles, and are carnivorous, feeding upon living or dead insect-larvae and frequently indulging in cannibalism; many have a very complicated colour-pattern of browns and blacks. The sub-imagines are always dull-coloured, the wings being either brown or ochreous. They fly straight out of the water, and rest upon a rock or the leaf of a tree for about two days. At the end of this time the imago emerges, a glittering, clear-winged creature which loves to dance in the evening sunlight over the rock-pools. These imagines certainly live a week or more, which is longer than

Atalophlebia australica (at rest).

usual for this order. The commonest species is *Atalophlebia australica,* a fly of about ¾ inch expanse, with a rich brown body and a dark brown band along the costa of the fore-wings. The hind-wings are, as usual, very small; the two outer caudal filaments are immensely long and strong, but the middle one is either absent or much reduced in size. This species is figured (enlarged) in the text-figure.

Süd-west Australiens (1907) and *Results of Mjoberg's Swedish Scientific Expeditions to Australia* (1917). R.J.T.

Plovers. See WADERS.

Plum, a name applied to several trees outside the genus *Prunus*, which is not represented in Australia. The black plum is a *Cargillea* (see EBENACEAE); the Queensland and sour plums are species of *Owenia* (q.v.).

Plums. See FRUIT-GROWING.

Plunkett, JOHN HUBERT (1802-1869), born in county Roscommon in Ireland in June 1802, educated at Trinity College, Dublin (B.A., 1824), and called to the Irish bar in 1826, threw himself at once into the agitation for Catholic emancipation and by his influence determined in favour of the Irish Catholics a critical election in 1830. In 1831 he was appointed solicitor-general of New South Wales, and reached Sydney in June 1832. In 1833 he was directed, much against his will, to relieve John Kinchela (q.v.) of all court work, and in 1836 succeeded him as attorney-general; this position he held for nearly 20 years, including a visit to England in 1841-3, during which he was consulted about the framing of the 1842 act for the better government of the colonies. He was a member of the old legislative council from 1836 to 1841. In August 1843 he was appointed a nominee member of the new council, but for a few months did not take his seat owing to an irregularity in the appointment. In 1848 he became chairman of the board of national education. In 1856, on the grant of responsible government to the colony, he retired on a pension, but stood for election to the new assembly and was returned by two constituencies, choosing to sit for Argyle. In January 1857 he resigned this seat on appointment to the legislative council, of which he was made president. In February 1858, however, he quarrelled with the premier (Charles Cowper) over an educational matter, was removed from the chairmanship of the board, and resigned his other offices, returning to the assembly (1858-60) as member first for Cumberland and then for West Sydney, and then retiring to the council, of which he was a member till his death. He represented the Martin ministry in the council from October 1863 to February 1865, and—having been reconciled to Cowper—in the hope of diminishing the evils of party government joined the succeeding Cowper ministry in August 1865 as attorney-general; but when, on the fall of that ministry the next year, he found himself unable to effect a Martin-Cowper coalition, he left politics and spent most of his remaining years in Melbourne, where he died on 9 May 1869. In 1835 he published at his own expense *The Australian Magistrate*, and in 1863 *The Evidence of Accomplices*. He was one of the original members of the senate of the university of Sydney, and from 1865 till his death was vice-chancellor.

Podargus. See FROGMOUTHS AND NIGHTJARS.

Poison-bush, a name applied (with distinguishing epithets) to indigenous plants of several families, sometimes inaccurately, sometimes because at certain seasons they are toxic though normally harmless. The bloom poison-bush is an *Oxylobium*, as is the box poison-plant; the Candyup poison-bush is a *Stypandra*; the dogwood and Ellangowan poison-bushes are species of *Myoporum*; the peach-leaved poison-bush (which is not toxic, but so fibrous in texture as to produce indigestion) is a *Trema*; the river poison-tree is an *Excaecaria*. Many species of *Gastrolobium* have, and nearly all species deserve, the same name; and other leguminous plants—e.g. the Darling pea, q.v.—have similar qualities.

Polding, JOHN BEDE (1794-1877), born at Liverpool in England on 18 November 1794, left an orphan at an early age and adopted by his uncle Dr. Brewer (who was president-general of the English Benedictines), was educated at Acton Burnell in Shropshire, admitted to the Benedictine order in 1811, and ordained priest on 4 March 1819. Appointed prefect—and later novice-master—of St. Gregory's College at Downside in Somerset, to which place the Acton Burnell school had been transferred in 1814, he embraced this work with a zeal that made him decline the offered bishopries of the Mauritius and of Madras. When, however, it was decided at Ullathorne's earnest request to detach Australia from the diocese of the Mauritius, and the new missionary bishopric was offered to him, Polding (who from youth had dreamed of work in Australia) yielded, and on 29 June 1834 was consecrated bishop of Hiero-Caesarea *in partibus infidelium* and made vicar apostolic of New Holland and Van Diemen's Land.

Reaching Sydney on 13 September, Polding at once set himself to provide an embryo organization for the vast diocese in his charge. This, however, was probably the least arduous of his duties; his most strenuous and remarkable work was done among the convicts, especially the new arrivals. Obtaining permission from the governor to have all Catholic newcomers left in his charge for a few days, he used to give them personal advice and exhortation both on religion and on their future behaviour and prospects, to such good purpose that only one or two out of thousands became criminals within the colony. The time not thus employed he spent in visits to the chain-gangs and road-gangs, or in long journeys to the settlements inland, well earning the praise later given him as 'the greatest missionary of the age.' On 29 June 1836 he consecrated the cathedral of St. Mary at Sydney, begun in 1820 by Father Therry (q.v.). In 1841 he visited Europe, and while in Rome was made (20 July 1842) archbishop of Sydney and metropolitan of Australia; this use of local names was thought by some opponents of his Church to be an infringement of the rights of the Anglican Church, and a formal protest was made by Bishop Broughton, without effect. Other visits to Europe, each resulting in the introduction to Australia of new agencies for religious work, were paid in 1846-7 (when Polding was given a coadjutor bishop), 1854-5, and 1865-7. In 1869 he left Australia to attend the Vatican council of 1870, but was unable at his age to stand the tropical heat, and returned to Sydney from Aden. He died at the Sacred Heart presbytery in Darlinghurst on 16 March 1877.

Of Archbishop Polding's work it is difficult to speak without appearing to exaggerate. When he reached Sydney in 1834, his Church was served by three priests, and he brought three more with him. By the end of his life the territory first placed under his jurisdiction had been divided into 12 dioceses—Sydney (1834), Hobart (1842), Adelaide (1844), Perth (1845), Port Victoria (1847), Melbourne (1848), Maitland (1848), Brisbane (1859), Bathurst (1865), Goulburn (1866), Armidale (1869), Ballarat (1874), and

Sandhurst (1874); and in the archdiocese of Sydney—a mere corner of his original diocese—there were 82 churches and 53 schools. Of his personal qualities contemporaries relate that his learning was equalled only by his industry and excelled by his piety. Richard Windeyer in 1843 described him as 'the person who possessed the greatest share of dignity and commanded the greatest respect and influence in the colony.' 'In his own Church,' wrote an Anglican in 1859, 'he is adored, in ours he is admired.' But nothing short of the full story of his life in Australia—which may be found in Birt's *Benedictine Pioneers*—can do justice to his worth and achievements.

Christened 'John,' he adopted the name 'Bede' at his entry into the Benedictine order. See ROMAN CATHOLIC CHURCH.

E.M.O'B.

Police. In the early years of Australian settlement, as in the England of those days, the maintenance of public order was purely a military matter. (It will be remembered that during the trial of Queen Caroline London ran grave risks because the guard regiments, which were relied on to maintain order, sympathized with the queen; the London police force originated from the Duke of Wellington's report on this episode.) Governor Phillip in August 1789 appointed a night-watch, selected from the best-behaved of the convicts; this grew into a so-called 'constabulary,' with constables stationed at Parramatta, Toongabbie, and the Hawkesbury as well as at Sydney. Hunter, finding in 1796 that at Sydney at least this force was not to be trusted, substituted for it a system whereby the town was divided into areas whose inhabitants had to choose three 'decent and respectable' fellow-residents as watchmen. On 1 June 1801 King ordered a weekly inspection of the 'police' at George's River and of the watchmen in Sydney. The police were under military control, supervised by John Harris, who was police magistrate at Sydney as well as surgeon of the New South Wales Corps; in 1802, when Paterson objected to the use of military officers for civilian duties, King discharged Harris and put Paterson himself in charge of police affairs—whereupon Paterson begged that Harris should be reinstated, and King, after a long delay—designed to teach Paterson a lesson—on 8 June 1804 granted the request. In 1807 Bligh dismissed Harris, replacing him with Robert Campbell, but in January 1809 Paterson put Harris back. His departure for England as a witness in the trial of Colonel Johnston gave Macquarie a free hand with the police. For a year he used patrols of his own regiment to maintain order in the streets at night, but on 1 January 1811 established a system of semi-civilian constables under a superintendent—D'Arcy Wentworth (q.v.) was the first—who was given 'power to punish all prisoners, freemen, rogues and vagabonds,' and had to keep a list of all householders and a 'black-book' of all offences and offenders. Sydney was divided into five districts, seven constables being allotted to each; at night the patrols 'called' every half-hour, and saw to it that householders closed their houses at a reasonable time. This system revived the principle of the curfew, and of hour-calling, but was progressive in that it provided civilian control under a single head.

For many years afterwards such changes as were made were the result rather of an alteration in material conditions than of any deliberately intended reform. The most important was the creation of a body of mounted police for service in country districts. When settlement began to spread beyond the Blue Mountains westwards, and up the Hunter valley to the north, it became obvious that some such body was needed to protect settlers from the convict bushrangers, and to regulate their relations with the aborigines. Accordingly, Governor Brisbane in 1824 organized a mounted police force by drafting from the troops in the colony (all infantry) men who could ride; they remained subject to military law, and wore a semi-military uniform. As the roads lengthened, and as the transport of valuable produce to Sydney grew in importance, the mounted police were called upon to protect it while in transit, and in several districts thus almost imperceptibly found themselves converted into the renowned 'gold escort.' For work of this kind the semi-military organization was most suitable, and it was not till well into the seventies that the mounted police became thoroughly civilianized.

With the appointment of J. T. Morisset in 1828 a more modern type of superintendent arrived, and further improvement resulted from an act of 1833 'for Regulating the Police in the Town and Port of Sydney.' This was followed in 1838 by another dealing primarily with the Hawkesbury; in 1840 increased powers were given to the water-police magistrates, and in 1842, when Sydney was incorporated, it was required to contribute 'one moiety of the cost of police'—a responsibility protested against and for some time evaded. On 1 January 1851 William Spain was appointed inspector-general, but retired at the end of the year. William Colburne Mayne followed him, and was succeeded in 1856 by John McLerie, who had been adjutant of mounted patrol, then governor of Darlinghurst gaol, and then superintendent of police. The uniforms worn at this time by police were:—ordinary, black coat, white trousers, 'bell-topper' hat; mounted, full dress, 'a becoming military uniform similar in every respect to that of the 13th light dragoons;' gold escort, a nearly full military uniform of similar character, described by Superintendent McLerie as 'most unsuitable.' The establishment of a true police-force in New South Wales was initiated by the police regulations act of 1862, which enacted that the inspector-general, under the direction of the colonial secretary, should control the entire police of the colony, making all appointments except those of inspectors, sub-inspectors, and the immediately subordinate grade of superintendents (in these cases the inspector-general recommended, and the governor-in-council appointed). The consolidating act of 1899 made no change in the system; in fact, the only important alterations since 1862 are a modification of the superannuation conditions in 1906, and the institution of a police appeals board in 1923. This board, and the formation of a police union, limits the autocratic power of the inspector-general without altering the principle of undivided control for the State.

The act of 1862 also put a definite term to the pretensions of the water police, and, more particularly, to the independent authority exercised by water-police magistrates. As at first Sydney consisted of little more than the waterfront, and as the perpetual arrival and despatch of government ships, arriving with convicts and leaving with time-expired troops, was the main event, in every sense, of the early years of

the colony, there had not unnaturally grown up a certain sort of precedence which made the 'water-police court' and its officers count themselves as of a higher grade. The act definitely reduces them to their proper level of subordination, and places them by special mention under the absolute control (so far as the police) of the inspector-general. Subsequently there grew up another and special body of water police and a special court, and a certain segregation of duty. On 1 September 1926 the strength of the New South Wales force was 2928, inclusive of 33 trackers.

Victoria.—In March 1837 Melbourne was guarded by one district and two ordinary constables; by October there were seven, but Lonsdale considered this force to be inadequate and procured several mounted men from Sydney. Disliking their appearance, he demanded that they should be supplied with some recognizable uniform—a scarlet waistcoat, he thought, would suit them well. It would seem that nothing came of this, for in the early forties the Melbourne police had a uniform of dark blue with pewter buttons and a top-hat with a glazed leather crown and upright side-bars of iron to protect them against brickbats and bottles. Throughout the Port Phillip district the bulk of the force was aboriginal, with white officers, but at Melbourne and Geelong a certain number of 'border police'—enlisted from refractory soldiers and ticket-of-leave men—were on duty; these, however, were disbanded towards the end of the forties. The first head of the Port Phillip police was Henry Batman, brother of the more famous John; he was not a success. Henry Pulteney Dana was the first head of the native police.

The sudden rise of Melbourne in 1852 to the status of a city—and a populous one—necessitated the creation of a genuinely civilian police force. The colonial office was asked to procure from the English and Irish police a number of trained men, and 50 constables arrived in the *Bangalore* and *Exodus* under a ten years' engagement, with the right to remain in the colony. Under Samuel Freeman (an imported officer) this nucleus expanded into a properly constituted and uniformed force of the true British civilian type. Despite the handicaps of poor material and of commissioners who—excellent officers though they were—had no sympathy with civilian organizations, Freeman successfully insisted on the extirpation, in Melbourne, at least, of the military ideals; the country districts he wisely left in charge of the military-minded officials. The native police, whom Dana had made into a fine body, began to decay after his death in 1852, and were soon extinct; they were revived more than 20 years later to deal with the Kelly gang.

With all Freeman's success, won against heavy opposition, the old type persisted in his superiors. The first three chief commissioners, H. F. Mitchell (1853-4), Charles McMahon (1854-7), and Frederick C. Standish (1858-80), were all of the military type and tradition. The first 'policeman' to hold office was H. M. Chomley (1881-1902). The higher air long remained too rarefied for a 'policeman' to breathe, yet even the chief commissionership capitulated at last.

Freeman's work is the more valuable because under him, directly or indirectly, all those who organized police in the other States (and even in New Zealand) were trained. Thus Edmund Fosbery, the first dominating inspector-general in New South Wales, was a Freeman-trained man; and Queensland and other colonies gladly borrowed from Freeman's staff men to set in order their own police establishments. In the sixties, however, through no fault of its author Freeman's organization in Victoria became less effective, and disorders arose which it took many years of stern effort to correct.

Police organization in the other colonies has less historical interest. *South Australia* consolidated a little later than Victoria: her system derives directly from Victoria: she has made two changes only; of these one is merely a matter of title—her head is styled 'commissioner;' the other, of more interest, that special constables cannot be created except by leave of the ministry of the day—a slight intrusion upon the absolute power of the commissioner. In South Australia the cost of the police force is divided equally between the district and the general revenues.

Queensland's consolidating act, passed in 1921, adds nothing of real moment. The strength of the Queensland force is 1113, i.e. 1 to every 762 of the population, almost the same proportion as in New South Wales; the cost is slightly higher than that in New South Wales. In *Western Australia*, considering its huge area, the cost is relatively low, and the proportion to inhabitants remarkably so. *Tasmania's* cost per head is the lowest: the ratio to population the highest except that in Victoria.

Native Police.—This force, which was in the early days separate and important, has disappeared from most States, but remains in Queensland and the Northern Territory. Native police must not be confused with black trackers (q.v.). In the Northern Territory there are 40 white and 40 native police, with varied duties, ranging from clerks' work to the dipping of cattle for ticks. Much of their time is taken up in finding and relieving parties of would-be explorers.

Commonwealth Police.—The Federal and Northern territories are policed by forces under Commonwealth control; expenditure in the Northern Territory is exceptionally high in proportion to the population—about £4 10s. per inhabitant—but this is unavoidable in a vast and scantily populated area. Further, police duties there consist largely of supervision of the aborigines, always a costly work. On special occasions small forces of Commonwealth police have been enlisted for work in the States—by W. M. Hughes when prime minister in 1917, and by Stanley Bruce, the present prime minister, in 1925; the last-mentioned force, required because the premier of New South Wales refused to allow the State police to act in certain Commonwealth matters, was officially named 'Commonwealth peace officers.' The Hughes force was disbanded when no longer required, and Bruce's force has been absorbed into the Commonwealth attorney-general's department.

Women Police.—In all the States except Queensland women police are employed, always in metropolitan areas and usually on preventive work only. Their superiors in South Australia (which has 10 of them) and Western Australia (which has 6) consider their work useful and important; New South Wales and Victoria have 4 each and Tasmania 2.

Police Associations.—Throughout Australia the police have been allowed to form what are virtually unions. In each State there is a police association; but, except in Queensland, these

associations have no access to the arbitration courts, and so the name 'union' has been carefully avoided. The Queensland association, however, makes full use of the arbitration court, and decisions to its advantage secured in Brisbane have a strong influence on police conditions in Sydney and, to a less degree, in Melbourne. Except for this access to arbitration courts the New South Wales association is typical. It is open to all members of the police 'of and under the rank of sergeant, 1st class.' Its executive is elected from the members, and its funds are vested in trustees. It may conduct business enterprises (e.g. the publication of a newspaper). Its objects are 'to promote by every means, consistent with the Regulations and with loyalty to throne and government, the interests of the Police Service, to afford means of discussing any matter relating to the general welfare of the police, to consider any grievance or complaint affecting the Force, and obtain redress through the proper channel, and finally, to encourage esprit de corps.' H.A.T.T.

In November 1902 the Victorian parliament passed an act abolishing pensions for members of the Victorian police force and substituting a compulsory scheme of insurance. This change did not prove altogether a success. Men joining the service found that, while one section was entitled to a pension on retirement, another was not; consequently there arose a certain discontent. For 20 years deputations waited on successive governments in the vain endeavour to obtain pension rights for the non-pensioners.

Shortly after the appointment of Chief Commissioner Nicholson (11 April 1922) four senior constables were appointed as special supervisors. These went in plain clothes from district to district in the metropolitan area to see that constables were properly performing their duties. To such supervision a number took exception, and among them there was drawn up a petition for the redress of what they termed legitimate grievances. This was signed by over 600 men, who pledged themselves to stand firmly by it and its consequences.

On 29 October 1923, 29 uniformed men, who were due to parade at Russell Street for night duty, refused to fall in for the roll call. The chief commissioner was informed, and hastened to the barracks. On arrival, after meeting with a hostile reception, he stated that he would remove the supervisors for the night and would consult the premier in the morning. The men then fell in and went on their beats. A conference took place between the chief commissioner and the premier, H. S. W. Lawson, who decided that the men must return to duty unconditionally while he placed their complaints before cabinet.

On 1 November the same men refused duty at 10 p.m., and the chief commissioner again went to Russell Street. The outlying stations had been instructed to send men to the barracks for duty, but on arrival these joined the strikers. After a futile attempt to address the men, the commissioner dismissed the two ringleaders, and discharged the others. During the night some of the seceders travelled from district to district in a motor-car, persuading the men on duty to cease work, and informing them that a mass meeting would be held in the morning. This meeting was largely attended, and, against the advice of several speakers, carried a resolution not to return to duty. There followed negotiations with the premier, but he remained firm, and that night the city went unpoliced. The following morning the chief commissioner and the attorney-general, Sir Arthur Robinson, addressed a number of men who had arrived at Russell Street from the country, with the result that most of these remained loyal. The mounted men and recruits in training were then addressed on the seriousness of the position, and besought to stand firm; but they joined the strikers, and left the depot.

On Saturday evening the city was crowded with visitors attending the spring racing carnival. The traffic became confused through the absence of traffic police; the rowdy element took charge of the city, and windows in the main thoroughfares were broken and goods stolen from shops. The detectives and plain-clothes men, assisted by the uniformed men who remained loyal, did yeoman service, and many arrests were made. Sunday saw a recurrence of rowdyism. The position was very serious. Cabinet met and decided on the formation of a special constabulary force under Major-general Sir J. W. M'Cay (q.v.). Volunteers enlisted in large numbers; prominent business men and their employees joined up. Depots were established, and the specials, armed with batons, for some weeks effectively policed the city and suburbs. This force was augmented by police pensioners who had been recalled for duty. The work of reconstructing the permanent force then began. By recruiting in both the country and the metropolitan area, a permanent force was soon in the making, the accepted candidates being put through intensive training and drafted to stations. These men, considering the short period of training, did remarkably well. Meanwhile the discharged men formed themselves into what was known as the Discharged Police Reinstatement Association.

Overtures made to the government on their behalf met with no success. In 1924, upon a change of government, a royal commission was appointed to enquire into (*a*) the general state and efficiency of the police force prior to November 1923; (*b*) any alleged grievances prior to that date; (*c*) the causes moving members of the force to refuse duty or strike in that month; (*d*) the consequences arising from such refusal or strike. General Sir John Monash was appointed chairman of the commission, 54 sittings were held in public, and 115 witnesses were examined.

The commissioners reported, *inter alia*:

> Having had a number of strikers before us as witnesses, and having had an opportunity of noting their demeanour and personality, we were surprised that such a large body of men who are above the average in intelligence, judgment, and experience, should have permitted themselves to be carried off their feet and to prefer to follow a self-constituted leader like Brooks rather than their own elected representatives on the Police Association. The motives which actuated these men were many and varied. Some, doubtless, had resentment at the system of supervisors uppermost in their minds; others either surrendered their judgment altogether, merely blindly following the crowd, or were actuated by a definite view that loyalty to comrades, right or wrong, came before loyalty to their service; while no inconsiderable number joined the strikers mainly out of fear of the consequences to themselves of remaining loyal to the service.

A.H.MacK.

Police Fund, The. The expenses of the early settlement were a charge on the British budget—which meant that the naval governors had to obtain leave from London before any important work could be carried out. The pro-

ceeds of the few customs duties that were levied at Sydney and Hobart were for the most part used in the upkeep of the female orphan school. Macquarie, from the first eager to make improvements without the delay involved in obtaining approval from London, determined to create a local fund for that purpose; on 3 March 1810 he doubled the duty on imported spirits (bringing it up to 3s. per gallon), and on 31 March allotted one quarter of the thus augmented customs revenue to the orphan school, and with the remainder established a 'police fund,' of which a mere modicum was to be spent on police. Out of it were 'to be defrayed the Expence of the Jail and Police Establishments, the Erection of Wharves, Quays, Bridges, and the making and repairing of Streets and Roads within the limits of the Town of Sydney.' In October 1810 market tolls and dues were also allotted to the fund, and it soon became a sort of colonial treasury. Liverpool in 1812 saw with apprehension the creation of such a fund, and, while he sanctioned it for the moment, warned Macquarie that very soon it must be used to relieve the British Treasury, not to finance a large public works policy; if the free settlers, he said, cannot pay for their own roads and wharves, it may be presumed that such roads and wharves are not really needed. Macquarie disregarded this warning with much success, and proceeded to use the fund for any purpose that occurred to him—e.g. in 1816 he drew on it for a reward to G. W. Evans (for his discoveries west of the Blue Mountains) and for raising the salary which the colonial office had allotted to the customs officer at Hobart. In 1820 the judge-advocate, John Wylde, told Bigge that 'there is no charge which can be made or arise in the Colonial Government that has not been from time to time defrayed out of the Police Fund.' At that time the principal sources of revenue were customs duties, public-house licences, and slaughter-house dues; more than half the salaries paid to civil officials (£9824 against £8475) were paid from the fund, and when the colonial office refused to pay D'Arcy Wentworth a salary as treasurer of it, Macquarie simply authorized him to retain out of it a sum equal to £100 a year during his term of office. A similar fund established at Hobart was similarly placed under the sole control of the lieutenant-governor of Tasmania; in 1821 it paid £2006 towards official salaries as against £2897 paid by the British Treasury.

Bigge, who might have been expected to recommend the abolition of the fund, merely commented on the various purposes to which it had been put. But the establishment in 1824 of a legislative council for the colony, with power to impose duties and vote moneys for civil expenditure, certainly implied the abolition of the fund, though no formal order for it was issued.

H.A.T.T.

Polygonaceae, a large family of plants dispersed over most parts of the globe, consisting of herbs, shrubs or climbers with small petal-less flowers clustered in the leaf axils, and scarious stipules which form a sheath round the branches. The genus *Rumex*, which contains the well-known rhubarb and docks, is widely distributed. Of the four species indigenous to Australia, three are endemic, the fourth extending to New Zealand. They are perennial herbs, with jagged brown stipules and small reddish flowers; *R. crystallinus* is an inland species. *Polygonum* is chiefly composed of herbs with knotted stems and small green or white flowers; of the 13 indigenous species one (*P. articulatum*) is endemic. *P. plebium*, a widespread prostrate herb, contains about 11 per cent of tannic acid. Of the seven indigenous species of *Muehlenbeckia* five are endemic; they are undershrubs or twiners, with flowers clustered within a sheathing bract, the sepals enlarging and becoming succulent with age. *M. Cunninghami* is a divaricately-branched, spiny shrub, upon which the leaves are frequently undeveloped. It forms on the inland plains dense thickets known as Lignum scrubs. *M. adpressa* (Native Ivy) has a sub-acid, currant-like fruit which was used by the pioneers for tarts, puddings, and preserves; its leaves taste like sorrel.

Polyosma, a small genus of the family Saxifragaceae, consisting of trees; a few species extend to India and the South Pacific islands. The flowers are white or greenish; calyx 4-toothed; petals narrow and short-lived;

Feather-wood, and fruit.

fruit an ovoid berry, with a large single seed; leaves irregularly opposite. *P. Cunninghami* (Feather-wood, the 'yeralla' of the Illawarra aborigines) has fragrant tubular flowers, fluted fruits, and a pale fissile timber.

Polyprotodonts. See MARSUPIALS.

Pongamia, a genus of the family Leguminosae, is limited to one species, *P. glabra* (Indian Beech), widely diffused over tropical Asia. It is a large tree, with leaves divided into numerous leaflets; flowers in pairs; pod broad and oblique, slightly curved, thick and flat. Dr. T. L. Bancroft states that all parts of the plant contain an active emetic principle. In India an oil (Poonga oil) is extracted from the seed and used as an illuminant; it is also used to cure various cutaneous diseases.

Population, GROWTH OF. The following table shows the growth of the Australian population from 1790 onwards, in ten-year periods up to 1820 and in five-year periods subsequently.

On 26 January 1788 there were altogether 1024 persons in the settlement then founded. On 31 December of that year, a party having been despatched to Norfolk Island, the population of Port Jackson was 859. On 31 December of the years hereunder stated the population of all the Australian settlements taken together, but excluding aborigines, was as follows:—

1790	2,056	1845	279,148	1885	2,694,518
1800	5,217	1850	405,356	1890	3,151,355
1810	11,566	1855	793,260	1895	3,491,621
1820	33,543	1860	1,145,585	1900	3,765,339
1825	52,505	1865	1,390,043	1905	4,032,977
1830	70.039	1870	1,647,756	1910	4,425,083
1835	113,354	1875	1,898,223	1915	4,970,054
1840	190,408	1880	2,231,531	1920	5,411,297

At the census of 4 April 1921, the last date on which the exact population was definitely ascertained, the numbers were 5,435,734, being less than two to the square mile. The official estimate for 31 December 1925 was 5,992,084.

The three periods of marked increase are 1810-20, 1830-40, and 1850-60, in each of which decades the population almost trebled. In 1810-20 the increase was chiefly due to an abnormal influx of convicts, nearly 17,000 arriving during the period. In 1830-40 the policy of assisting immigration from the proceeds of land-sales was in full swing. In 1850-60 the discovery of gold was the dominant attraction. When the influx of would-be gold-diggers slackened, the rate of growth declined considerably. From 1858 to 1889, while immigrants were still being assisted by several colonies, the average yearly rate of increase was 3½ per cent; between 1889 and 1918 it was only 1¾ per cent, but this average includes a minimum of 1⅝ in 1902-6 and a maximum of over 2 in 1907-11. In recent years the rate has averaged just below 2 per cent.

On 31 December 1925, according to the official estimate, population was distributed among the States as follows:—New South Wales, 2,298,442; Victoria, 1,684,017; Queensland, 861,185; South Australia, 551,633; Western Australia, 372,183; Tasmania, 217,032. In the Northern Territory there were 3635 persons, and in the Federal Capital Territory 3936.

The proportion of town-dwellers to country-dwellers is of grave importance. In 1871 about 27 per cent of the population lived in the six colonial capitals, 19 per cent in smaller towns, and the remainder (54 per cent) in the country areas. By the end of 1906 the population of the six capitals had increased to 35½ per cent of the total, and by 1924 to 45½. In Victoria and South Australia the metropolitan population exceeds half the total. The occupational census of 1921 tells a similar story:—

Percentage of Bread-winners.

	1871	1881	1891	1901	1911	1921
Professional class	5.1	5.5	6.2	6.8	7.4	8.7
Domestic	11.5	12.2	11.6	12.3	10.3	9.1
Commercial	8.1	9.2	12.3	13.6	14.6	15.3
Transport	3.8	4.5	6.8	7.5	8	9
Industrial	26.5	29.5	30.7	26	28.7	31.2
Primary Producers ..	44	38.2	30.7	32.5	29.9	25.8

The almost steady decline of the primary producers is alarming, especially since it is due, not to a corresponding growth in secondary industries, but largely to the disproportionate growth of the professional and commercial classes. In 1871 17 per cent of the bread-winning population sufficed to do the business, transport, etc., for the 70 per cent who were engaged in production of some sort. In 1921 only 57 per cent were producing, and 33 per cent were carrying, trafficking, or professionally employed.

See MIGRATION. The *Official Year Book of the Commonwealth* No. 18 (1925) deals fully with recent developments and with the several factors of increase; *Year Book* No. 15 (for 1922) has a special article on censuses and on the methods of compiling estimates of population.

Porcelain Crab. See HERMIT CRABS.

Porcupine-fishes, members of the family Diodontidae, related to the well-known toadoes or puffers, which they closely resemble in both form and habits. They differ principally in the many strong spines that cover their skin and form an effective armament against enemies. Some species have short and stout spines; in others they are long and almost bristle-like; and they are provided with spreading roots, sometimes so large as to maintain the spines permanently erect. Like the toadoes, porcupine-fishes can inflate themselves with water or air—this causes the spines to stand out stiffly, and so renders them unsafe to touch. Further, their flesh is often highly poisonous, and they are therefore better left alone.

Porcupine-fishes occur in all seas, and a number of different species are recorded from Australian waters, ranging from the warm shallows of the tropics to the cold depths. A common species in Port Jackson, *Dicotylichthys punctulatus*, is white, with numerous black, round spots. Others, in the tropics, are marked with large ocelli, and still others have broad blackish bands crossing the back. A.R.McC.

Port Darwin. See NORTHERN TERRITORY.

Port Essington. See NORTHERN TERRITORY.

Port Jackson. See HARBOURS and SYDNEY.

Port Jackson or Bull Head Sharks, a remarkable group of sharks of the family Heterodontidae, of which the first living representative was secured in Port Jackson and made known by Governor Phillip, after whom it was called *Heterodontus philippi*. Various allied species have since been found in other parts of the world; fossil remains of related forms, known from as far back as the Carboniferous period, indicate that the family was far more plentifully represented in Palaeozoic and Mesozoic times than at present. The teeth of the Port Jackson shark are extraordinary scroll-like structures, formed by the fusion of several adjacent teeth, and are adapted for crushing the shells of small animals upon which they feed. Two species of the family are known from Australian waters. Both deposit eggs of remarkable form; the central cavity is pear-shaped, and provided with two ribbons of a flexible horn-like material that extend in spirals round it. In one species these spirals terminate abruptly at the base, and serve to hold the egg securely when it becomes wedged in among rocks. In the other the spirals are produced into two long tendrils, which twine round marine growths and so keep the egg safely in position until the young shark hatches out. These sharks attain a length of four feet and are quite harmless to man. A.R.McC.

Port Phillip. See HARBOURS and MELBOURNE.

Portuguese Men-of-war. See BLUEBOTTLES.

Portulaca, a genus of the family Portulaceae, consisting of 14 species of succulent herbs, most of which are endemic in Australia. The cosmopolitan species *P. oleracea,* in Europe known as Purslane or Pigweed, is used as food by aborigines on the Cloncurry River in Queensland; they collect the plants in a heap which they turn over at intervals, partly to dry it, partly to let the seeds fall out from the capsules. The seeds are washed, ground in stone mills, and eaten raw, forming a highly nutritious food which, while it lasts, keeps the consumers in splendid condition. The succulent leaves are also eaten raw; their taste resembles that of watercress, and they are said to be anti-scorbutic. Of *P. napiformis* both seeds and roots are eaten. See FODDER-PLANTS.

Portulaceae, a small family of herbs, chiefly American, with a few species in South Africa and Australia. Three genera and 32 species are indigenous to Australia. *Calandrinia* has 22 species, chiefly endemic. *C. balonensis* is an inland species extending from South Australia into northern Australia; aborigines mix it with baked bark, and use it as a food. *C. polyandra* (the Coonda of the natives of Western Australia, who use it as a food), also ranges across the inland districts of the continent. Sheep are very fond of it and, while feeding on it, can subsist for a long time without water. This quality belongs to most Australian members of the family. See PORTULACA.

Posidonia. See MARINE FIBRE.

Possession Island. See EXPLORATION BY SEA.

Posts and Telegraphs. *New South Wales.*—For 23 years after the first settlement of New South Wales there were no regular post-offices in operation, and only the most imperfect means of postal communication; the bulk of the correspondence then circulating consisted of government despatches and official communications, and these were carried by constables, who were also allowed at times to carry settlers' letters. The first mention of any other form of letter-delivery occurs in the *Sydney Gazette* of 10 July 1803—regulations for the passage-boatmen between Sydney and Parramatta, which authorized a charge of 2d. each for the carriage of private letters.

On 25 April 1809 Lieutenant-governor Paterson issued the following order:

Complaints having been made to the Lieut Governor that numerous frauds had been committed by individuals repairing on board ships on their arrival at this port and personating others, by which they have obtained possession of letters and parcels to the great injury of those for whom they were intended.

The Lieut Governor, in order to prevent the practice of such frauds in future, has been pleased to establish an office at which all parcels and letters addressed to the inhabitants of this Colony are to be deposited previous to their distribution, which office shall be under the direction of Mr. Isaac Nichols, assistant to the naval officer, who has entered into security for the faithful discharge of the trust reposed in him.

The following regulations are, therefore, to be observed, viz:—

On arrival of any vessel, Mr. Nichols, or a person properly authorised by him, is to repair on board, and to require that all letters and parcels, directed for the Colony, be delivered to him, for which he is to give a receipt to the master, mate, or supercargo.

An office for their reception shall be established at his house, and in consideration of the trouble and expense attended on the duty, the following sums shall be charged by him on their delivery, viz:—

For every letter, 1s.

For every parcel not exceeding 20 lb. weight 2s. 6d., and

For all exceeding that weight, 5s.

A list to be published in the *Gazette* of the names of persons to whom letters and parcels are directed.

Soldiers' letters (agreeable to the established regulations) to be charged only one penny.

On 23 June 1810 Governor Macquarie issued a similar order in which the charges were varied, and the scope of Nichols's duties somewhat widened. Nichols's house in High-street (now George-street) under this order became a regular post-office. Nichols died in 1819; his successor, George Panton, who acted also as wharfinger, did all his work in a small office on the King's wharf.

Up to 1825 postal arrangements in the colony were not legislated for, probably because under an act passed in the reign of Queen Anne the power to 'settle' posts for the carrying and receiving of letters within British dominions was vested in the postmaster-general of the United Kingdom. In November 1825, however, Brisbane put through the legislative council an act to regulate the postage of letters in New South Wales. This act made reference to that of Queen Anne, as well as to the fact that no post had been established in New South Wales by the postmaster-general of Great Britain; affirmed the expediency, in the meantime, of providing for the temporary postage and conveyance of letters; gave power to establish post-offices in the colony and to fix rates of postage, and provided that all postage collected was to be paid to the treasury. A proclamation issued under it set out the rates of postage, the salaries and allowances of postmasters, and the regulations for their guidance, and invited tenders for the conveyance of mails between Sydney and Parramatta, Windsor and Liverpool, Liverpool and Campbelltown, and from Parramatta to Emu Plains and thence to Bathurst. In 1828 a system of general postal communication was established, and new rates of postage were fixed, depending upon distance and the difficulty of transmission—the lowest inland single rate was 3d. and the highest 1s., the postage on a letter increasing according to weight; the minimum fee was charged on weights up to a quarter of an ounce. The fee for newspapers was 1d. Letters from New South Wales to Tasmania cost 3d. each; other letters by ship cost 4d. each, single rate, and 6d. for any weight in excess. In the same year postmasters were appointed at Bathurst, Campbelltown, Liverpool, Newcastle, Penrith, and Windsor, and arrangements were made for the conveyance of mails either by contract with private individuals or by the mounted police. The Sydney staff in 1828 consisted of a chief postmaster (usually called the postmaster-general), one clerk, and one letter-carrier; there were also eight country postmasters, and a letter-carrier at Parramatta, who received as his sole remuneration a penny for every letter he delivered.

George Panton died in 1829, and was succeeded by James Raymond. In 1829-30 fairly regular services were given to the settled portions of the colony, extending approximately 120

miles south of Sydney and 238 miles west. In 1831 a regular 2d. post was inaugurated for Sydney, and unpaid 'receipt boxes' were fixed in different parts of the town and cleared twice a day. The only place at which letters could be 'post paid' was the chief post-office. Postage revenue at that time (and for many years afterwards) was collected directly in cash at the post-offices or on delivery. Stamped covers were introduced in 1838 to be sold at 1s. 3d. per dozen, and letters enclosed in them were delivered in Sydney without further charge. After 1834 mounted troopers ceased to carry letters, contracts for the conveyance of mails being substituted. In that year a post-office was established at Moreton Bay. An act of 1835 ordained fresh rates of postage, at the same time increasing the initial weight for letters from ¼ oz. to ½ oz. Inland letters were still chargeable according to distance, the minimum charge (4d.) covered 15 miles, and for 300 miles the charge was 1s., with 1d. for each additional 100 miles. In 1837 a post-office was established at Melbourne. In 1838 another act amended the rates and increased the charge on ship-letters. The following figures show the expansion between 1828 and 1838:—

	1828	1838
Revenue	£598	£8,390
Expenditure	£890	£10,357
Number of offices	8	40
Inland letters	15,598	168,551
Inland newspapers	34,832	297,245

The Sydney staff in 1838 consisted of a chief postmaster (called postmaster-general), an accountant, six clerks, six letter-carriers, and an office-keeper. In the same year a town delivery of letters in Sydney was instituted, and (on 4 December) the first overland mail was despatched to the settlement at Port Phillip. This service ran fortnightly via Liverpool, Campbelltown, Berrima, Goulburn, and Yass, at each of which places mails were made up. At the request of senders, and on prepayment of inland and sea rates, correspondence for Launceston, Hobart, and Adelaide could be sent by this route. In 1840 communication by steamer was established with Melbourne, the charge for a single letter being 1s. 3d., as by land; in the following year the first steamboat plied to Moreton Bay. In 1844 was initiated a monthly service with the United Kingdom by contract packet, the first vessel to arrive under this arrangement being the *Mary Sharp* on 11 June. An act of 1849 consolidated and amended the postal laws, abolished the privilege of 'franking' letters (which had been allowed to the principal officials), and extended the exclusive right of the post-office to carry letters and packets, making it applicable to packets weighing up to 16 oz. instead of 4 oz. as previously.

In May 1851 Raymond died and was succeeded by F. L. S. Merewether, who soon resigned to become auditor-general; Major Christie then became postmaster-general.

On 1 July 1851 all post-offices in the Port Phillip district were withdrawn from Sydney's jurisdiction. A consolidating act of 1851 authorized postmasters to refuse packets or letters which weighed more than 16 oz. or contained anything likely to injure the contents of the mails, made prepayment of postage on letters (other than those to the United Kingdom) compulsory, and allowed newspapers to go through the post free of charge if posted within seven days of publication. Prepayment of postage by stamps became obligatory from 1 May 1852, and by an act passed in December of that year maps, charts, books, and music were allowed to circulate in the colony at a reduced rate of postage. In 1854 negotiations were concluded with the British post-office for the exchange of letters at the uniform rate of 6d. per ½ oz.

In 1855 carriage of mails by railway was initiated, and glass-fronted private letter-boxes were installed in the general post-office at Sydney. At this time there were 155 post-offices in operation in New South Wales, 71 of which exchanged direct mails with Sydney. The staff numbered 223, of whom 56 were located in Sydney. In 1856 improved means of obliterating stamps were introduced, and to exercise a check on individual offices the stamp of each office was given a different number. In 1858 3,551,773 letters and packets and 2,808,140 newspapers passed through the post, the revenue for the year amounting to £39,953, and the expenditure £69,507. The number of post-offices in operation was 221.

On 10 December 1859 Queensland became a separate colony, thus reducing the length of postal lines in New South Wales by 1558 miles, and the number of post-offices by 15. In 1862 a board appointed to enquire into post-office management recommended that the position of postmaster-general be a political and independent office, and that a new general post-office be erected; consequently in 1863 the office was temporarily removed from George-street to a building in Wynyard-square. In October 1862 a money-order system was established under the control of the treasury, but was transferred to the post-office when, on the retirement of Major Christie in 1865, the position of postmaster-general was made a political and ministerial office. The first political head of the department was James A. Cunneen.

In 1867 the electric telegraph department was transferred to the control of the postmaster-general. This department had been established under the control of the minister for public works in 1857, and in 1858 Edward Charles Cracknell—who had been brought from England by Charles Todd, superintendent of telegraphs in South Australia—was appointed superintendent of telegraphs in New South Wales. He still occupied that position when the transfer to the post-office took place. A short telegraph-line (the first erected in the colony) was opened between Sydney and South Head on 26 January 1858, and in the following October the line to Albury, connecting with the Victorian line from Melbourne, was completed. The line connecting Sydney and Brisbane was opened in November 1861.

After the transfer many post- and telegraph-offices were amalgamated, and this operation was practically completed by 1870. Travelling post-offices on the railways were first established in 1870, when special vans for the carriage of mails, in charge of mail-guards, were provided on the southern line, and fitted with letter-boxes, so that letters could be posted at places along the line. In September 1871 a government savings-bank system was inaugurated under the control of the postmaster-general; by April 1872 there were 53 branches in operation, the amount to the credit of depositors being £14,226. In 1872 a penny post was established for Sydney, and was extended in the following year to the municipalities within a radius of 10 miles. On 1 September 1874 the new general post-office in Sydney was opened. In 1881 a

private telephone service was established at the Sydney stock exchange in Bridge-street, which in 1882 was taken over by the government and placed under the control of the postmaster-general. In 1893 an inland and inter-colonial parcels post was established, and the postal-note system introduced.

Although the electric telegraph department, the money-order service, and the savings-bank department had been transferred to the control of the postmaster-general, each continued to be administered as a separate entity by an officer having direct access to the minister. In 1893, however, it was decided to secure economy and efficiency in administration by incorporating these sections with the postal service in one department, under one permanent head, who would act as adviser to the minister and be responsible under him for the administration of the whole department. Stephen Harbord Lambton was made permanent head, with the designation of deputy postmaster-general, and retained that office until the transfer of the department to the Commonwealth on 1 March 1901.

Victoria.—In July 1836 John Batman, at the request of the principal settlers of Port Phillip, undertook to look after their correspondence, and may therefore be said to have been the first postmaster in Melbourne. Letters and fees were received at his house, and those for Tasmania and Sydney were entrusted by him to the masters of sailing-vessels trading with those settlements. The first officially appointed postmaster seems to have taken up duty on 13 April 1837, the only mails received and despatched at that time being conveyed by sailing-vessels between Sydney and Tasmania; but the postal service was under the control of the postmaster at Sydney till 1851. In January 1838 the overland mail first ran to Sydney. In January 1839 the first direct mail was despatched to England, by a barque named the *Thomas Laurie*. In December 1840 the *Clonmel*, the first steamer to arrive at Port Phillip with mails, reached Melbourne from Sydney. In 1841 the first government building for postal purposes was erected in Melbourne, and a town delivery of letters by carrier was commenced on 10 August. In August 1842 H. D. Kemp, an officer of experience from Sydney, was appointed postmaster, with general supervision of postal matters in the province. In 1844 receiving-boxes were erected at each end of the town, clearances taking place twice a day, except on Sunday. In 1847 mails were exchanged with Adelaide; they were sent by steamer to Geelong, thence overland to Mount Gambier, whence they were carried by South Australian troopers to Adelaide. In 1849 the number of post-offices had increased to 36; the staff in Melbourne consisted of one postmaster, five clerks, and four letter-carriers; the revenue was £6951, and the expenditure £7542.

The first Victorian postage act, passed in 1852, established rates within the colony:—not exceeding ½ oz., 2d.; above ½ oz. but not exceeding 1 oz., 4d.; thereafter 4d. per oz. or fraction thereof.

The year 1853 was one of exceptional activity owing to the stream of immigrants drawn to the colony by the gold discoveries:—

	1851	1853
Letters handled	544,425	2,038,999
Newspapers handled	450,741	1,618,789
Post-offices in operation	43	54
Staff	17	97
Revenue	£7,929	£25,733
Expenditure	£11,483	£73,040

The first electric telegraph-line in Australia was erected between Melbourne and Williamstown. S. W. McGowan, who had studied telegraphy under Professor Morse, arrived in Victoria early in 1853, with the intention of forming a private company to establish and work telegraph-lines between Melbourne, Sydney, Adelaide, Ballarat, and Sandhurst (Bendigo). He brought with him instruments, batteries, and other necessary material, but during his negotiations the government decided to take the matter into its own hands, and in September 1853 invited tenders for the construction of a line between Melbourne and Williamstown. McGowan's offer for the work was accepted, and communication between the two places was established in January 1854, though the line was not fully opened to the public until 3 March. McGowan then received the appointment of general superintendent of telegraphs.

In 1854 a new postage act increased postage rates to 2d., single rate for town letters; 6d., single rate for inland letters; and 1s. for ship letters. An act of 1855, however, reduced the rates for inland and ship letters to 4d. and 6d. respectively. Before 1857 the post-office service had been under the treasury, but in April of that year William Henry Fancourt Mitchell was appointed postmaster-general with ministerial control.

On 1 July 1858 the money-order system was introduced, and in the same year cast-iron letter-receivers were erected in Melbourne, and delivery by letter-carrier in the suburbs was made three times a day. In 1869 the post and telegraph departments were amalgamated under W. Turner as deputy postmaster-general. In 1871 the central telegraph-office was transferred from William-street to Elizabeth-street.

The post-office act of 1883 increased the initial weight for letters to 1 oz.; authorized the postmaster-general to prohibit delivery of letters to persons engaged in lotteries, race-sweeps, or other illegal occupations; vested in him the sole right of constructing, leasing, or otherwise providing for public use telegraph- and telephone-lines; and made it an offence to send through the post articles containing indecent or obscene prints, photographs, etc. The issue of postal notes was commenced in 1885. At that time there was a private telephone company in Melbourne, whose charges were alleged to be exorbitant; efforts were made to buy out the company, which asked £78,750, but accepted £40,000, and on 22 September 1887 the government took over the business. In the same year the first railway-carried mails were exchanged between Melbourne and Adelaide. Letter-cards were introduced in 1889, and the rate of postage on letters reduced from 2d. to 1d. single rate. In 1890 special trains were first used for the carriage of English mails between Adelaide and Melbourne, the cost being apportioned between Victoria, New South Wales, and Queensland on a population basis.

The following table shows the development of the postal service between 1841 and 1901:—

Year.	Post-offices.	Letters and post-cards.	Newspapers.
1841	3	56,000	120,000
1861	369	6,110,000	4,277,000
1881	1158	26,308,000	11,441,000
1901	1637	82,599,000	26,297,000

Queensland.—A post-office is said to have been opened at Brisbane in 1834, but the earliest

official record of a post-office in Queensland is that relating to the appointment of one White as postmaster at Brisbane in 1842. Offices were opened at Drayton in 1845, Ipswich in 1846, Warwick in 1848, Gayndah and Maryborough in 1849, and Nanango in 1850. By 1852 the work of the post-office at Brisbane had so increased as to necessitate individual attention, and Captain J. E. Barney was appointed in that year, a town delivery by letter-carrier being also instituted. Captain Barney died in 1855, and his widow took over his duties. In 1858 post-offices were opened at Toowoomba and Rockhampton.

Queensland was made a separate colony on 10 December 1859, and soon afterwards Robert Ramsay Mackenzie, the colonial treasurer, became acting postmaster-general. The staff in Brisbane at this time consisted of a postmistress, three clerks, two letter-carriers, and one messenger and sorter. Iron letter-receivers were erected there in 1860, in which year also the first issue of Queensland postage-stamps, printed in England from dies prepared there, was circulated.

Complaints having been made about the irregularity of the service, parliament in 1861 authorized the appointment of a non-political postmaster-general, and Thomas L. Murray-Prior was given the post on 6 November. The staff of the general post-office then consisted of a postmaster-general (also postal inspector), a postmistress, an accountant (also secretary and cashier), four clerks, two sorters, and four letter-carriers—13 in all. The revenue in the colony was £6348 and the expenditure £16,064. On 1 August 1861 a savings-bank was established in Brisbane. A branch of the general post-office was opened in Ipswich in 1862, and in the same year the money-order system came into operation.

In 1865 the government decided to abolish the position of permanent postmaster-general and appoint a responsible minister of the crown as postmaster-general, with ministerial control of the postal and electric telegraph departments—the latter had been under the colonial secretary. Murray-Prior accordingly retired, and on 1 March 1866 John Douglas assumed office as postmaster-general with ministerial status. Shortly afterwards the government of which Douglas was a member was defeated, and Murray-Prior returned to the department on 21 July 1866 as its ministerial head for seven weeks. He held the position also from August 1867 to November 1868 and from May 1870 to January 1874.

During 1866 70 steamers carrying 378 mails left Brisbane for the northern ports of Queensland, and during 1867 83 steamers carrying 483 mails. At the end of 1867 the revenue was £19,906, and the expenditure £33,444. In 1870 a permanent head of the department was appointed, with the title of under-secretary, John McDonnell being transferred to the position. The original portion (post-office) of the general postal building in Brisbane was opened in 1872. Travelling post-offices were established in January 1877 on the Brisbane-Warwick and Brisbane-Dalby railway-lines.

In 1879-80 the post and telegraph departments were amalgamated, the under-secretary being appointed permanent head of the combined department. The telegraph department had been previously in charge of a superintendent of telegraphs (J. J. Austin in 1861-3 and W. J. Cracknell in 1863-80), who occupied offices in William-street some way from the post-office. A general inspector for the Northern district, located at Bowen, had immediate control of the telegraph service in the northern part of the colony. The first telegraph-line in Queensland was erected in April 1861, connection with Sydney by wire being made in the same year. The line to Normanton and Burketown was erected in 1871, and the line to Cape York in 1887. Post-cards and postal notes were issued in 1880, in which year also a telephone service was initiated, several government departments being placed in communication with one another through an exchange to which private lines were subsequently connected. In June 1881 there were 36 instruments in circuit with the exchange.

A contract of 1881 for the conveyance of mails to Europe via Torres Straits brought about a reduction in the rates of postage from the colony to the United Kingdom. These rates had been, for letters via Brindisi 9d. per ½ oz., via Southampton 6d. per ½ oz. Under the new arrangement the charges per ½-oz. for letters were as follows:—

All the way by sea via Torres Straits	4d.
via Torres Straits and Brindisi	6d.
via Melbourne and Brindisi	9d.
via San Francisco	8d.

The first mail-steamer via Torres Straits arrived in December 1883. At the beginning of 1888 the railway-line to Sydney (with the exception of the Hawkesbury bridge) was opened for traffic, and thereafter all mails for the southern colonies were sent overland. The rate of postage on letters to the United Kingdom was reduced to 2½d. per ½ oz. in 1890, and from 1 October 1891, the date on which the Australian colonies became members of the universal postal union, that rate applied to letters to all countries which had entered the union.

In 1891 an agreement was made between the governments of Queensland and New South Wales and the Société Française des Télégraphes Sous-Marins de Paris for the laying of a cable from Queensland to New Caledonia, on a guarantee for 30 years of a subsidy of £12,000 per annum, £8000 to be paid by the French government, and £2000 each by the governments of Queensland and New South Wales. The laying of this cable was completed in 1893, the terminus in Queensland being Burnett Heads near Bundaberg. The rates charged for cablegrams between Queensland and the United Kingdom were reduced on 7 July 1897 from 9s. 5d. to 5s. 1d. per word. In 1898 an express delivery service was organized, and telephone regulations were framed to assist station-holders and others in outlying districts in obtaining telephonic communication with the nearest available telegraph-office. In 1899 John McDonnell, who had been permanent head of the department since 1870, retired, and was succeeded by Robert Townley Scott, who later became permanent head of the postmaster-general's department under the Commonwealth.

South Australia.—On the first establishment of the colony in 1836 Thomas Gilbert, the colonial storekeeper, was directed to act as postmaster, an allowance of £30 a year being made to him; mails were received, sorted, and delivered at his residence. A uniform charge of 1d. was made on all letters received and despatched, the proceeds being paid to masters of the ves-

sels conveying them. This arrangement appears to have continued until December 1838, by which time the work had so increased as to justify the appointment of Henry Watts as postmaster-general. Under the first local post-office act, passed in 1839, the rate of inland postage was fixed at 3d. per letter or packet, irrespective of weight or size; on ship-letters only 1d. was charged, to cover the gratuity to ships. In the same year a post-office was opened at Port Adelaide, with a daily mail to and from the city; an office was opened at Port Lincoln, and a fortnightly mail, carried by the police, was instituted between Adelaide, Willunga, and Encounter Bay; and in Adelaide delivery by letter-carrier was commenced.

Henry Watts resigned in 1841, and on 1 April a Captain Watts succeeded him; there were then only six post-offices in the colony, but one at Gawler was opened during the year. Under an act of 1841 inland letters were charged according to distance (maximum 2s. 6d.) and the postage on newspapers was abolished; during 1842 the inland rate of postage was imposed (in addition to the ship rate) on all ship-letters posted or delivered at country post-offices. Up to 1843 members of the council and the governor's private secretary had power to 'frank' other persons' private letters; in 1843 this extraordinary privilege was abolished, and inland postage was reduced to a uniform rate of 4d. for each ½ oz., with half-rates for letters between Adelaide and Port Adelaide and those posted for town-delivery. The inland postage on ship-letters for and from the interior was discontinued. In 1853 a private-box system was put into operation. Postage-stamps were introduced in 1855—2d. on 1 January, and 1d. and 6d. on 26 October; thenceforward prepayment of postage, by means of stamps, was compulsory. The stamps were obtained from England.

The first telegraph-line erected in the colony (from Adelaide to Port Adelaide) was opened for business in February 1856. In 1855 the government had asked the colonial office to appoint a superintendent of telegraphs; Charles Todd (q.v.) was appointed, and arrived in Adelaide in 1855, with an assistant, E. C. Cracknell. Work on the line to Port Adelaide was put in hand almost immediately. A private line erected by James Macgeorge between the same places was opened just before the completion of the government line, and was ultimately purchased by the government and dismantled. A line between Adelaide and Melbourne was commenced in April 1857, and opened for traffic on 21 July 1858.

Captain Watts retired on 30 June 1861, and was succeeded by W. J. Lewis; he held office until 1869, when the government decided to amalgamate the post and telegraph department under Charles Todd as 'postmaster-general and superintendent of telegraphs.'

Before 1848 post-office business was conducted at the private residence of the postmaster; in that year it was removed to a building afterwards known as the Gresham Hotel, from which in June 1851 it was transferred to the government buildings north of Victoria-square. On 1 November 1867 the Duke of Edinburgh laid the foundation-stone of the building at the corner of King William- and Franklin-street, which was completed and occupied in 1872; and in this (with alterations and extensions) the department is still housed.

In 1872 the transcontinental line to Darwin (2230 miles) was completed (see OVERLAND TELEGRAPH-LINE), and on 9 December 1877 the line from Adelaide to Perth was opened for traffic. The post-office act of 1876 brought post-office law and practice in South Australia into line, as far as possible, with those of the other colonies. On 8 December of that year post-cards were issued. The telephone exchange in Adelaide was opened on 14 May 1883, with 48 subscribers. An act of 1886 authorized the issue of postal notes, and another legalized the parcels-post; postal notes were issued on 1 March 1887, but the parcels-post was not established until 1889.

Western Australia.—Arrangements for handling postal matter in Western Australia seem to have been first made in 1830, when J. Purkis of Perth, and Lionel Samson of Fremantle, acted as receivers of mails at those places. An act to establish a postal department was passed by the legislative council in 1834, Charles McFaull being shortly afterwards appointed postmaster at Perth, and J. Bateman postmaster at Fremantle. An act of 1837 provided that the postmasters at Perth, Fremantle, and Albany should be independent officers, responsible only to the colonial secretary. McFaull resigned in 1840, his place being taken by E. Picking on 12 March in that year—on which date the post-office was removed to a room in the public buildings. In 1841 a weekly mail was established between York and Guildford, and a monthly one between Perth and Albany (King George's Sound). In the following year a regular mail-service was established with all the settled districts and H. Camfield succeeded Picking as postmaster-general. In 1853 A. Helmich, who had been made permanent head of the department (postmaster-general), removed the general post-office to premises in Murray-street, but it was taken back to the public buildings in 1857. In 1863 a post-office savings-bank was opened; in the same year a money-order system was established with the United Kingdom and other places outside the colony, but its extension to places within the colony did not take place until 1876.

In June 1869 a private electric telegraph-line was erected between Perth and Fremantle. This, the first in the colony, was taken over by the government in 1871. The initiation and the early and rapid extension of the government telegraph-service was due, in a great measure, to the zeal and energy of James Coates Fleming, the first superintendent of telegraphs; he retained the position until his death in 1885. By May 1877 1515 miles of line had been erected, and 23 telegraph-offices brought into communication with Perth. The total value of telegraph business for 1876 was £3780.

In 1878 the government instituted its own road-service between Albany and Perth to carry English and intercolonial mails, with a limited number of passengers and parcels; the result was satisfactory, and in January 1880 similar services were established in the south-eastern and eastern districts—all controlled by the police department in co-operation with the post-office. Halfpenny post-cards were issued in 1879. In 1887 the first telephone exchange was established at Perth, and in 1888 at Fremantle; the service was controlled by the works and railways department, and was not transferred to the post and telegraph department until 1 January 1890. The office of postmaster-general was held successively by A. Helmich (1885-7), C. F. Ga-

han (1887-9), and R. A. Shole (1889-1901). The office of postmaster-general in Western Australia, as in South Australia, was always filled by a departmental officer, never by a cabinet minister.

The cable between Roebuck Bay and Batavia was opened for traffic on 9 April 1889; it was used only for messages to and from Western Australia, except when interruptions occurred on the overland line between Adelaide and Darwin. The laying of the Cape-Australian cable connecting Perth with South Africa was completed on 30 October 1901. In 1889 the great southern railway was opened, and a travelling post-office was established between Albany and Perth. The new general post-office in St. George's-terrace was formally opened on 27 August 1890. In 1895 a travelling post-office was installed on the Midland railway, and the system was extended to other main lines as opportunity offered.

The following table indicates the development of the service between 1861 and 1901:—

Year.	Post-offices.	Letters and post-cards.	Newspapers.
1861	14	193,000	138,000
1881	52	995,000	715,000
1901	187	17,451,000	7,975,000

Tasmania.—The first Tasmanian post-office is said to have been opened at Hobart in 1809. In 1812 John Beaumont was appointed postmaster there, with permission to retain all postages collected in the colony as remuneration for his services; he was also allowed rations for himself and two servants. In 1814 he was succeeded by James Mitchell, who held office until 1822. In October 1816 it was arranged that mails should be carried by a government messenger between Hobart and Launceston; he was to leave Hobart on Sunday, walk the 120 miles, and leave Launceston on the return journey on the following Sunday. Up to that time the settlement on the Tamar had been more isolated than Hobart, since few vessels entered the Tamar River. A messenger also carried letters to Coal River and to Sorell on Pitt Water. In 1822 John Thomas Collicott succeeded Mitchell as postmaster at Hobart, and Arundel Wright was appointed postmaster at Launceston. By 1828 the Hobart-Launceston messenger had been allowed a horse, and called at Greenponds, Old Branch, Bagdad, Constitution Hill, and various inns and private houses; from Greenponds and other centres messengers on foot carried mails to Black Marsh, the Clyde, the Shannon, and places adjacent. Mails were also conveyed from Launceston to Georgetown and from Hobart to New Norfolk; mails for Sorell and Orielton went by boat; to Oyster Bay a messenger was despatched once a week, or as often as the state of the weather, river, and roads permitted. The rate was 3d. per ½-oz. letter for the first 10 miles, with a proportionate increase for longer distances.

In July 1832, the post-office having been made a government department, the clerk of the council and the acting auditor of civil accounts were constituted a committee for 'regulation of the post;' Collicott was made principal postmaster and given the services of a clerk. There were then 25 post-offices in operation and 36 messengers were employed at 'post stations' for the receipt and delivery of letters. In May 1833 the committee was dissolved, and a 'director-general of the post-office department' (Captain James England) appointed; at this time mails were carried between Hobart and Launceston twice a week by a one-horse mail-cart. A postal act of 1834 appointed Collicott postmaster-general, and established a general post-office in Hobart and branch post-offices throughout the territory; postage on letters not exceeding 4 oz. in weight, posted in Hobart or Launceston for delivery in the same town, was fixed at 2d.; if intended for delivery at a distance of 2-15 miles, 3d.; 15-30 miles, 4d.; 30-45 miles, 5d.; and so on in proportion. Letters carried by sea cost 4d. per single letter in addition to the inland rate; and newspapers directed to persons more than 60 miles away were charged 1d. each—if under 60 miles, ½d. In 1835 messengers at branch post-offices were withdrawn on account of the expense, but were afterwards replaced by prisoners holding tickets of leave, who worked on a promise of emancipation for continued good conduct. The general post-office at Hobart, which had been situated in Murray-street, was removed in 1836 to the corner of Collins- and Elizabeth-street. Collicott died in 1840, when Captain F. C. Smith was appointed, and held the office till 1858.

By an act of 1842 a uniform rate of postage according to weight, irrespective of distance, was introduced; ½-oz. letters delivered beyond Hobart and Launceston were charged 4d., those posted and delivered within Hobart and Launceston 2d., and those for places oversea 4d. The postage on newspapers was abolished in September of the same year. A money-order system was inaugurated on 25 September 1852. An act of 1853 made prepayment by stamps compulsory, and reduced the rate for town letters from 2d. to 1d. An act of 1858 established a 'suburban' rate of 2d., applicable within five miles of the Hobart and Launceston post-offices. In 1858 the position of postmaster-general was abolished, and the permanent head of the department (Stephen Tunbridge Hardinge) was called secretary to the post-office.

The first electric telegraph-line was erected between Hobart and Launceston in 1857, and on its completion W. H. Butcher was appointed superintendent of telegraphs under the control of the public works department. A cable between Tasmania and the mainland was laid in 1859, but had a life of a few weeks only; it was not until 1869, when a second cable had been laid, that the colony was permanently connected with the telegraph-systems of the other colonies. Another cable was completed in February 1909 at a cost of £49,455. Telephone exchanges at Hobart and Launceston were opened in 1883, and at New Norfolk in 1888. The post-office act of 1881 fixed the rate for town letters at 1d. and for inland letters at 2d. A government savings-bank was instituted in 1882, and the amalgamation of the post and telegraph departments was effected in 1894.

Oversea Mail-services.—In 1844 the first monthly-contract sailing-packets reached Melbourne from the United Kingdom, and until 1852 oversea mails to and from Australia were carried by transports and other sailing-vessels; in that year the Peninsular and Oriental Company's steamer *Chusan* arrived in Sydney on 3 August via the Cape of Good Hope, followed later in the year by the Royal Mail Steam Navigation Company's steamer *Australian*, under a contract made by the British government for the conveyance of mails every alternate month. The service was, however, not satisfactory, and in 1853 a contract was entered into with the Peninsular and Oriental Company for a service

every alternate month from Singapore to Sydney, via King George's Sound, Adelaide, and Melbourne. The *Shanghai*, the first vessel to arrive under this contract, reached Adelaide on 14 May 1853. In 1857 the British government contracted for a monthly service between Southampton and Sydney, and in 1859 for a monthly service via the Mauritius; in 1860 Point de Galle in Ceylon was substituted for the Mauritius. This contract remained in operation until 1873. In 1866-8 a line of steam-packets ran from Sydney to Panama via Wellington, and in 1869 a monthly service from Sydney to San Francisco via Auckland was inaugurated. The last of the San Francisco contracts expired in 1906, since which date Australian mails have been carried by that route on a poundage basis. In 1873 Victoria contracted for a service to Point de Galle, New South Wales for a service to San Francisco, and Queensland for a service to Singapore. Contracts were also made by the Queensland government in 1881 and subsequent years for the conveyance of mails to the United Kingdom via Torres Straits and Suez; but the principal mails between Australia and Europe have been carried by the Peninsular and Oriental and Orient companies, via Suez.

Oversea Cables.—The cables connecting Australia with places oversea are:—

Darwin-Banjuwangi (Java). Completed in 1871.
Sydney-New Zealand (Eastern Extension Company). Completed in 1876.
Darwin-Banjuwangi (duplicate). Completed in 1879.
Sydney-New Zealand (duplicate). Completed in 1890.
Burnett Heads (Queensland)-New Caledonia. Completed in 1893.
Fremantle-Durban, via Cocos. Completed in 1901.
Southport (Queensland)-Vancouver Island (Canada). Completed in 1902.
Sydney-New Zealand (Pacific Cable Board). Completed in 1912.

International Postal Congresses.—In 1897 the Australian colonies and New Zealand (represented by John Gavan Duffy, postmaster-general of Victoria, and James Smibert as *fonctionnaire attaché*) took part at Washington for the first time in a congress of the Universal Postal Union, to which they had been admitted in accordance with a decision of the previous congress held at Vienna in 1891. Subsequent congresses were held as follows:—

1906 Rome—
Austin Chapman, postmaster-general
Justinian Oxenham, *fonctionnaire attaché*
1920 Madrid—
Justinian Oxenham, secretary of the postmaster-general's department
James Kay, *fonctionnaire attaché*
1924 Stockholm—
W. G. Gibson, postmaster-general
James Kay, *fonctionnaire attaché.*

Intercolonial Postal Conferences, to deal with oversea mail arrangements, oversea cables, and general postal and telegraphic matters affecting the Australian colonies, were held in 1867, 1877, 1878, 1883, 1888, 1889, 1890, 1891, 1892 (2), 1893, 1894, 1896, and 1898; at the first of the two conferences held in 1892 a draft Australian postal convention was adopted. At some of these conferences New Zealand was represented.

Commonwealth.—The proclamation constituting the Commonwealth of Australia as from 1 January 1901 having been issued on 17 September 1900, the permanent heads of the State post and telegraph departments met in Sydney in November-December of that year to draft a Commonwealth consolidating post and telegraph bill, and to suggest other arrangements for the working of the department under federation. The Commonwealth post and telegraph act of 1901 practically embodied their principal recommendations, and provided for the management of the department by a postmaster-general (a responsible minister with cabinet rank), a permanent secretary with chief control under the minister, and a deputy-postmaster-general in each State.

Sir John Forrest, the first postmaster-general appointed, did not take over the duties, his term of office extending only from 1 to 17 January 1901; J. G. Drake succeeded him on 5 February. On 1 March 1901 the department was transferred by proclamation to the Commonwealth, but the State departments continued to function under State law, pending the passing of a federal post and telegraph act. No steps were taken to appoint administrative staffs to the various Commonwealth departments, but Justinian Oxenham (private secretary to the postmaster-general) acted as official secretary to the postal department until June 1901, when the central administration was constituted with Robert T. Scott as secretary and permanent head. In December 1901 the Commonwealth post and telegraph act came into operation, but State rates, charges, and regulations remained in operation until revoked. Commonwealth regulations came into force on 30 June 1902; uniformity as regarded rates charged for the conveyance of newspapers and the transmission of telegrams was secured by a rates act which took effect from 1 November 1902; but State charges for letters, post-cards, and packets remained unaltered until 1 May 1911, when the rates act of 1910 came into operation. This act inaugurated penny-postage throughout the Commonwealth for ½-oz. letters. Victoria had had penny-postage for years within its own borders, but in other States the rate had been 2d. per ½-oz. letter, except within certain town limits. Owing to the book-keeping provisions of the constitution act (which operated for a period of ten years after federation) each State had to continue using its own postage-stamps, which were not available for the prepayment of postage in another State. The need for continuing this arrangement disappeared in 1910, and from October of that year stamps of any State might be used to prepay postage in any part of the Commonwealth. The issue of a Commonwealth stamp followed soon afterwards (see PHILATELY).

In 1905 a wireless telegraphy act was passed, and tenders were accepted in 1910 for the erection of two high-power stations, one near Sydney, and the other near Fremantle; but it was not until after 1911, when an engineer for wireless telegraphy (J. G. Balsillie) was obtained from England, that that section of the department was organized for general service round the coast of Australia (see RADIO-TELEGRAPHY). In 1907 a conference with the railway departments of the States resulted in an agreement for a uniform charge for the conveyance of mails by rail.

Sir Robert Scott retired from the position of secretary on 31 December 1910, after 47 years' service; Justinian Oxenham succeeded him on 1 January 1911, and was himself succeeded on 17 December 1923 by H. P. Brown—an officer with distinguished service in the British post-office, who had been lent to the department in an advisory capacity for 12 months.

The expansion of the department since federation is indicated by the following figures:—

Year.	Offices in operation.	Letters and post-cards.	Newspapers.	Revenue.	Expenditure.
				£	£
1901–2	4,994	238,000,000	116,000,000	2,372,861	2,478,796 (gross).
1924–5	10,020	692,043,000	173,148,000	10,074,854	9,2[illegible]0,629 (working).

The amount spent on new works in 1903-4 was £37,149; in 1924-5 the capital expenditure on fixed assets and plant was £5,450,681.

See OVERLAND TELEGRAPH-LINE, PACIFIC CABLE, PHILATELY, and SAVINGS BANKS. J.O.

Potamogetonaceae, a family of aquatic plants, marine or fluvial, with six genera indigenous to Australia. *Posidonia* has one endemic species, and one found in the Mediterranean and on the European shores of the Atlantic; both are submerged maritime plants, covering large areas in shallow water along the coasts. *P. australis* (Sea-grass or Sea-wrack) extends from Western Australia to New South Wales, and is very plentiful in Spencer and St. Vincent gulfs, where it has been exploited on a commercial scale for some years. It is rolled up into felted balls by the action of the waves, and thrown up on the beach in great quantities. The fibre manufactured from it has been used in paper-making, and for weaving into a coarse cloth, as well as for carpet-making (see MARINE FIBRE). *Ruppia* is limited to a single species, *R. maritima* (Sea Tassel), a slender herb with thread-like branches that forms a tangled network in brackish lagoons in most temperate and subtropical regions.

Potatoes. In 1798 Hunter reported that out of a cultivated area of about 6200 acres 14 were laid down in potatoes, and Bligh in 1807, writing 'The Gardens are now giving Supplies of Potatoes,' explained that this was due to his having 'demanded personally the exertions of everyone to this culture.' It is evident, therefore, that (as might be expected from more recent experience) potatoes did not grow easily in the comparatively poor soil of the Sydney district. The colonial office, however, could not be brought to believe this, and at the end of 1807 Bligh was rebuked for leaving the crop out of his calculations—in London they knew that potatoes were 'a certain crop in the colony.' Under Macquarie in 1811 potatoes accounted for 123 acres out of 5278 cultivated, and in 1821 (when the spread of settlement west of the Blue Mountains was beginning to show results) 737 acres out of 32,269; in Tasmania the proportion was lower—14 acres out of 871 in 1811, and 95 out of 10,050 in 1820. By 1828, however, the special suitability of the Tasmanian soil had been discovered, and Darling told the colonial office that New South Wales grew potatoes 'chiefly for the Table and of an excellent quality, but little inferior to those of Van Diemen's Land and New Zealand, whence, particularly from the former, considerable quantities are imported.' In 1834 the Tasmanian potato crop was 7114 tons, grown on 2495 acres out of a total of 69,217 cultivated. During the 1840s two new centres of potato-growing were opened up—the Pambula district on the south coast of New South Wales, and the since famous Warrnambool district in western Victoria.

At the present time the potato is cultivated chiefly in Victoria, Tasmania, and New South Wales where under suitable conditions of soil and climate it reaches a high state of perfection. Only in the two southern States does supply exceed demand; they, however, supply the needs of the other States, and only in years of exceptional drought is it necessary to import New Zealand potatoes.

Victoria generally produces more than half the total Commonwealth crop. The rich volcanic soils of the Portland Bay and Warrnambool districts are especially famed for their productiveness. In proportion to population, however, Tasmania has by far the greatest yield, especially in the north-west, where is grown the well-known 'Circular Head' crop. The Brown's River and Huon River districts have also produced large quantities for many years. The average production per head of population in Tasmania for the past five seasons is 7.5 cwt. as against 2.6 cwt. for Victoria. In New South Wales excellent crops are grown (*a*) round Guyra, Armidale, and Orange on the high tablelands, where there is a considerable area of volcanic soil and a good rainfall, and (*b*) in the rich alluvial soils of the Hunter and Clarence river districts; but the Orange district produces one-third of the total yield. The high cost of railway carriage to the central markets, compared with the cheaper water transport from Victoria and Tasmania, is a handicap to the New South Wales industry. In South Australia potato-growing shows a marked progress, the average for the past ten seasons being 3.47 tons per acre. In recent years the dreaded 'Irish blight' has made its appearance, but vigorous measures for its suppression have succeeded to a considerable extent. The area under potatoes, yield and value for 1924-5 was as follows:—

	Area (acres)	Yield (tons)	Value (£)
New South Wales ..	23,044	49,485	419,310
Victoria	61,196	169,863	910,733
Tasmania	32,109	82,094	608,652
Other States	16,691	44,649	496,394
Commonwealth	133,040	346,091	2,435,089

The Native Potato (*Gastrodia sesamoides*), which is really an orchid, is indigenous to all the States except South Australia; it is also known as 'potato orchid' and 'black man's potato.' Its tubers are of the size, and almost of the shape, of kidney potatoes, and are attached by thick fleshy fibres to the root of some tree on which the orchid is parasitic. The Tasmanian aborigines roasted them for food—their taste resembles that of beetroot. W.S.C.

Pottinger, SIR FREDERICK WILLIAM (1831-1865), born in India on 27 April 1831, was the second son of Lieutenant-General Sir Henry Pottinger, a distinguished public servant who was political resident in Cutch (1835-40), British envoy to China (1841-2), first governor of Hong Kong (1843-4), governor of The Cape Colony (1846), and governor of Madras (1847-54), and in April 1840 was made a baronet for his services in India. Frederick about 1856 migrated to New South Wales, and in that year succeeded to his father's title. He secured employment in the police force, just then beginning its long warfare against the bushrangers of the gold-rush period, and in 1862 was inspector in charge of the Lachlan goldfield.

He thus came into close contact with the gang led at first by Frank Gardiner (q.v.) and afterwards by Ben Hall (q.v.), and had little success against either leader. His repeated failures to arrest Gardiner, even when he had him at arm's length with eight police in the neighbourhood, and his avowed belief that Gardiner had nothing to do with the Eugowra escort robbery (see BUSHRANGING), raised much ill-feeling in Sydney and made him the subject of many jeers and suspicions. Ben Hall he certainly did his best to capture—indeed, it was probably Pottinger's arrest of Hall in June 1862, before he had joined any gang, that drove him into Gardiner's arms. For two years Pottinger strove to keep the Lachlan roads safe for traffic and incidentally to hunt down the gang, and by the middle of 1864 was so hampering Hall's movements as to force him southwards into the Goulburn-Gundagai district. In January 1865, however, it was reported that Hall and a friend had been spectators at the Wowingragong racecourse (near Forbes) while Pottinger took part in a race there; the report was probably false, as Hall was then operating near Goulburn, but in March Pottinger was recalled to Sydney to explain the matter. On his way there his pistol exploded accidentally, giving him a fatal wound, and he died on 9 April.

Pouched Mice, a name generally applied to a group of small marsupials which, though mouse-like in size and to some extent in general appearance, have in reality little in common with the true mice (Rodentia) or harvest mice (Insectivora). The pouched mice are members of the family Dasyuridae, which includes also the native cats (q.v.). Pouched mice belong to five genera—*Phascogale, Chaetocercus, Sminthopsis, Antechinomys,* and *Dasyuroides*—and altogether some 22 species have been described from Australia and Tasmania. One of the best-known of the smaller kinds is the Common Pouched Mouse (*Sminthopsis murina*), a slender, mouse-like animal whose head and body together are about 3½ inches long, and tail about the same; its fur is soft, fine, and gray, and its ears of variable size. Its hinder parts are of slaty flesh-colour, its hands and feet white, and the slender tail is covered uniformly with short hair. It occurs over the whole Australian mainland outside the tropics, as does the comparatively large, grayish, Brush-tailed Pouched Mouse (*Phascogale penicillata*), a sub-species of which (*P. p. pirata*) occurs in Arnhem Land in the Northern Territory. The Lesser Brush-tailed Pouched Mouse (*P. calura*) is similar to *penicillata,* but is considerably smaller and of a more brownish general coloration; it is also more rare, and has been recorded from south-western and south Australia, as far north as Alice Springs, but it is not possible to define its present range. The Pigmy Pouched Mouse (*P. minutissima*)—which is only 5½in. in length including the tail—is only found in central and southern Queensland; the Little Pouched Mouse (*P. minima*) is confined to Tasmania and the neighbouring islands; Swainson's Pouched Mouse (*P. swainsoni*), occurring in Tasmania as well as Victoria and New South Wales, is a medium-sized strongly-built species of a sombre, grizzled, dark brown colour. The Yellow-footed Pouched Mouse (*P. flavipes*) ranges from Papua to South Australia. The Long-tailed Pouched Mouse (*P. longicaudata*) is an inhabitant of the Aru Islands.

Some pouched mice are arboreal, and make nests among branches, or in hollows in the trunk or limbs of trees. Others live in burrows, and some in holes among rocks, and under stones. In general their diet is of an animal nature, and consists largely of insects.

The 'Jerboa' Pouched Mouse (*Antechinomys laniger*), which is an inhabitant of the far interior of New South Wales and southern Queensland, gets its name from its long kangaroo-like feet, long brushy tail, and habit of locomotion by a series of leaps or hops. A second species (*A. spenceri*) has been described from Charlotte Waters, and it doubtless inhabits central and northern South Australia. Both species are very rare. The so-called long-snouted pouched or honey-mouse (q.v.) is a phalanger. See MARSUPIALS.

W.A.H.

Praed, ROSA CAROLINE, born in southern Queensland on 27 March 1851, in 1872 married Arthur Campbell Mackworth Praed, nephew of the poet W. M. Praed. In 1876 she migrated to London and soon afterwards began a series of Australian novels, the first (*An Australian Heroine*) appearing in 1880. She also collaborated with Justin McCarthy in a series of novels dealing mainly with British political life. At the time of publication her Australian work was considered brilliant and life-like, reproducing as it did scenes of Queensland life in Brisbane and on stations which she knew well; but with the changes in Australian politics, and the advent of more broadly representative Australian fiction-writers, her novels are neglected.

Pratincoles. See WADERS.

Pratt, SIR THOMAS SIMSON (1797-1879), born in 1797 and educated at the university of St. Andrews, joined the army in 1814 (ensign, 1814; captain, 1825; lieutenant-colonel, 1841; colonel, 1862; major-general, 1873; lieutenant-general, 1878). He served in the Netherlands in 1814-5 and in China in 1841. In 1856 he was appointed to command the British forces in Australia (with the local rank of major-general), and conducted a campaign against the Maoris in 1860-1; on his return to Australia he took command of the forces in Victoria. He left Australia in 1862, retired from active service in 1877, and died in England on 2 February 1879. (C.B., 1841; K.C.B., 1861.)

Prawn-killer. See CRAYFISHES.

Prawns and Shrimps, marine or freshwater crustaceans belonging to three tribes of the sub-order Macrura, order Decapoda; three other tribes of the sub-order contain the crayfishes. They are generally distinguished by the great size of the abdomen, which is symmetrical and not folded under the body but carried more or less extended rearwards. The last pair of abdominal appendages (uropods), which are often wanting in the other groups, are always present in the Macrura, and are generally broad and flattened, forming, with the median-placed telson, a 'tail-fan.' Members of the first tribe (Peneidea) are characterized by the possession of certain structural features that distinguish them from a great number of superficially similar forms which are commonly confused with them by the casual observer; the first three pairs of legs are usually chelate (i.e. bear small pincers at their tips), and the side-plates of the second abdominal segment (somite) do not overlap those of the first. The common commercial prawns

of Australia are representatives of the Peneidea, and fall into the typical family Peneidae.

Australian prawns provide an industry of considerable economic value. They are secured by netters in shallow bays and estuaries of the more populous parts of the Commonwealth, and are generally plentiful between the months of October and March. Very little is known of their migrations beyond the fact that they occasionally appear in large numbers, and then almost completely disappear again. The three common species are the School Prawn (*Penaeopsis macleayi*), the King Prawn (*Peneus plebejus*), and the Tiger Prawn (*P. esculentus*). The school prawn, the smallest of the three, is in great demand as bait for fishermen. When alive, it is semi-transparent and covered with small reddish spots. The mottled colours of the king are distinctly pleasing; blue predominates; the swimmerets and tail are prettily marked. This species commonly attains a length of six inches, and, on account of its uniform size, is in greatest demand for consumption. The largest of the three is the handsome tiger prawn, readily recognized by the brown, tiger-like stripes that extend across its sides; specimens 12 inches in length have been recorded from Port Jackson. Egg-bearing or 'berried' females of the tribe Peneidea have never been observed, and it is now practically accepted that the ova are cast adrift singly in the water. From the scant data to hand regarding the larval stages of these crustaceans, it seems that they quit the egg at a very much earlier stage than do any of the other higher forms. The earliest known stage was discovered by Fritz Müller in 1864, and proved to possess a structure like that of the larval nauplius form so frequent among the groups of smaller Crustacea.

Peneus plebejus.
